## ABSTRACT

### Background

Coenzyme Q10, or ubiquinone, is a non-prescription nutritional supplement. It is a fat-soluble molecule that acts as an electron carrier in mitochondria, and as a coenzyme for mitochondrial enzymes. Coenzyme Q10 deficiency may be associated with a multitude of diseases, including heart failure. The severity of heart failure correlates with the severity of coenzyme Q10 deficiency. Emerging data suggest that the harmful effects of reactive oxygen species are increased in people with heart failure, and coenzyme Q10 may help to reduce these toxic effects because of its antioxidant activity. Coenzyme Q10 may also have a role in stabilising myocardial calcium-dependent ion channels, and in preventing the consumption of metabolites essential for adenosine-5'-triphosphate (ATP) synthesis. Coenzyme Q10, although not a primary recommended treatment, could be beneficial to people with heart failure. Several randomised controlled trials have compared coenzyme Q10 to other therapeutic modalities, but no systematic review of existing randomised trials was conducted prior to the original version of this Cochrane Review, in 2014.

### Objectives

To review the safety and efficacy of coenzyme Q10 in heart failure.

### Search methods

We searched CENTRAL, MEDLINE, Embase, Web of Science, CINAHL Plus, and AMED on 16 October 2020; ClinicalTrials.gov on 16 July 2020, and the ISRCTN Registry on 11 November 2019. We applied no language restrictions.

### Selection criteria

We included randomised controlled trials of either parallel or cross-over design that assessed the beneficial and harmful effects of coenzyme Q10 in people with heart failure. When we identified cross-over studies, we considered data only from the first phase.

### Data collection and analysis

We used standard Cochrane methods, assessed study risk of bias using the Cochrane 'Risk of bias' tool, and GRADE methods to assess the quality of the evidence. For dichotomous data, we calculated the risk ratio (RR); for continuous data, the mean difference (MD), both with

95% confidence intervals (CI). Where appropriate data were available, we conducted meta-analysis. When meta-analysis was not possible, we wrote a narrative synthesis. We provided a PRISMA flow chart to show the flow of study selection.

## Main results

We included eleven studies, with 1573 participants, comparing coenzyme Q10 to placebo or conventional therapy (control). In the majority of the studies, sample size was relatively small. There were important differences among studies in daily coenzyme Q10 dose, follow-up period, and the measures of treatment effect. All studies had unclear, or high risk of bias, or both, in one or more bias domains. We were only able to conduct meta-analysis for some of the outcomes. None of the included trials considered quality of life, measured on a validated scale, exercise variables (exercise haemodynamics), or cost-effectiveness.

Coenzyme Q10 probably reduces the risk of all-cause mortality more than control (RR 0.58, 95% CI 0.35 to 0.95; 1 study, 420 participants; number needed to treat for an additional beneficial outcome (NNTB) 13.3; moderate-quality evidence).

There was low-quality evidence of inconclusive results between the coenzyme Q10 and control groups for the risk of myocardial infarction (RR 1.62, 95% CI 0.27 to 9.59; 1 study, 420 participants), and stroke (RR 0.18, 95% CI 0.02 to 1.48; 1 study, 420 participants).

Coenzyme Q10 probably reduces hospitalisation related to heart failure (RR 0.62, 95% CI 0.49 to 0.78; 2 studies, 1061 participants; NNTB 9.7; moderate-quality evidence).

Very low-quality evidence suggests that coenzyme Q10 may improve the left ventricular ejection fraction (MD 1.77, 95% CI 0.09 to 3.44; 7 studies, 650 participants), but the results are inconclusive for exercise capacity (MD 48.23, 95% CI -24.75 to 121.20; 3 studies, 91 participants); and the risk of developing adverse events (RR 0.70, 95% CI 0.45 to 1.10; 2 studies, 568 participants).

We downgraded the quality of the evidence mainly due to high risk of bias and imprecision.

## Authors' conclusions

The included studies provide moderate-quality evidence that coenzyme Q10 probably reduces all-cause mortality and hospitalisation for heart failure. There is low-quality evidence of inconclusive results as to whether coenzyme Q10 has an effect on the risk of myocardial infarction, or stroke. Because of very low-quality evidence, it is very uncertain whether coenzyme Q10 has an effect on either left ventricular ejection fraction or exercise capacity. There is low-quality evidence that coenzyme Q10 may increase the risk of adverse effects, or have little to no difference.

There is currently no convincing evidence to support or refute the use of coenzyme Q10 for heart failure. Future trials are needed to confirm our findings.

## PLAIN LANGUAGE SUMMARY

### Coenzyme Q10 for heart failure

Heart failure is a term used to describe the state that develops when the heart cannot maintain adequate cardiac output, or can do so only at the expense of overfilling the heart chambers. People with heart failure commonly experience a relapsing and remitting disease course, with periods of stability and episodes of decompensation (failure to cope with heart damage), leading to worsening symptoms that necessitate hospitalisation.

Treatment options for heart failure range from drugs to heart transplantation, with each having its own limitations. Coenzyme Q10 (or ubiquinone) has been suggested as a treatment option in some trials. Coenzyme Q10 is a non-prescription nutritional supplement. It is a fat-soluble molecule that has a role in energy production within the cells of the body. It may also have antioxidant properties.

Low levels of coenzyme Q10 may be related to the severity of heart failure. Coenzyme Q10 has been found in all tissues and organs in the body, with the highest concentrations in the heart. Emerging data have suggested that the harmful effects of reactive oxygen species (unstable molecules that contains oxygen and easily reacts with other molecules) are increased in people with heart failure. Because of its antioxidant activity, coenzyme Q10 may help to reduce these toxic effects, which damage the components of the cardiac cells, and disrupt cellular signalling. Coenzyme Q10 plays an important role in conducting signals within the heart muscle and in generating energy. The concentration of coenzyme Q10 has been inversely related to the severity of heart failure. Supplementation with coenzyme Q10 may improve heart failure. Coenzyme Q10 is sometimes used because it is thought to have an acceptable safety profile, with no significant side effects.

We conducted this review to assess the available evidence on the effects of coenzyme Q10 in people with heart failure. We included 11 randomised controlled trials, involving 1573 participants. They were relatively small, and followed up participants for a relatively short period of time. The analyses show that coenzyme Q10 probably reduces the risk of mortality from all causes, and hospitalisations due to heart failure. It may result in increased, or little or no difference in the risk of myocardial infarction, stroke, or adverse events. The effect of coenzyme Q10 on cardiac function and symptom improvement is uncertain.

---

The evidence, current to October 2020, is of a moderate quality at best, because of the high risk of bias in some of the included studies and the absence of precise and consistent results. There is currently no convincing evidence to support or refute the use of coenzyme Q10 for heart failure.

## SUMMARY OF FINDINGS

### Summary of findings 1. Coenzyme Q10 compared to placebo or conventional therapy for heart failure

#### Coenzyme Q10 compared to placebo or conventional therapy for heart failure

**Patient or population:** people with heart failure

**Setting:** outpatient departments

**Intervention:** coenzyme Q10

**Comparison:** placebo or conventional therapy

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	N° of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with placebo or conventional therapy	Risk with coenzyme Q10				
<b>All-cause mortality</b> <i>follow-up: 26 months</i>	Study population		RR 0.58 (0.35 to 0.95)	420 (1 RCT)	⊕⊕⊕⊕ Moderate <sup>a</sup>	Coenzyme Q10 probably reduces all-cause mortality
	179 per 1000	104 per 1000 (63 to 170)				
<b>Myocardial infarction</b> <i>follow-up: 26 months</i>	Study population		RR 1.62 (0.27 to 9.59)	420 (1 RCT)	⊕⊕⊕⊖ Low <sup>a, b</sup>	The results for the effect of coenzyme Q10 on risk of myocardial infarction are inconclusive.
	9 per 1000	15 per 1000 (2 to 88)				
<b>Stroke</b> <i>follow-up: 26 months</i>	Study population		RR 0.18 (0.02 to 1.48)	420 (1 RCT)	⊕⊕⊕⊖ Low <sup>a, b</sup>	The results for the effect of coenzyme Q10 on risk of stroke are inconclusive.
	28 per 1000	5 per 1000 (1 to 41)				
<b>Hospitalisation for heart failure</b> <i>follow-up: mean 19 months</i>	Study population		RR 0.62 (0.49 to 0.78)	1061 (2 RCTs)	⊕⊕⊕⊖ Moderate <sup>c</sup>	Coenzyme Q10 probably reduces hospitalisation for heart failure.

\***The risk in the intervention group** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

**CI:** confidence interval; **MD:** mean difference; **RCT:** randomised controlled trial; **RR:** risk ratio

#### GRADE Working Group grades of evidence

**High certainty.** We are very confident that the true effect lies close to that of the estimate of the effect

**Moderate certainty.** We are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different

**Low certainty.** Our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect

**Very low certainty.** We have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect

<sup>a</sup>Downgraded by one level due to indirectness. The findings are applicable only to the characteristics of participants and dosing regimen as included in this one study.

<sup>b</sup>Downgraded by one level due to imprecision. The effect size has a very wide confidence interval that includes the possibilities of substantial harm, no difference, and a lower risk with coenzyme Q10.

<sup>c</sup>Downgraded by one level due to risk of bias. The included study that contributed most weight to the analysis had unclear risk for selection, detection, and reporting biases, and high risk for attrition bias.

<sup>d</sup>Downgraded by one level due to imprecision. The effect size has a very wide confidence interval that includes the possibility of only a minimal benefit with coenzyme Q10.

<sup>e</sup>Downgraded by two levels due to substantial risk of bias. Within the 7 included studies, selection bias was unclear in 6, performance bias was high in 1, detection bias was unclear in 3 and high in 1, attrition bias was high in 4, reporting bias was unclear in 3 and high in 1, and other bias was high in 1.

<sup>f</sup>Downgraded by two levels for imprecision. The effect size has a very wide confidence interval that includes the possibility of substantial harm, no difference, and a lower risk with coenzyme Q10. Also, the sample size is small.

<sup>g</sup>Downgraded by one level due to risk of bias. The 3 included studies had unclear risk of selection and detection biases, and high risk of attrition bias. Two of them also had unclear risk of reporting bias.

<sup>h</sup>Downgraded by one level due to indirectness. The findings are applicable only to the characteristics of participants and dosing regimen as included in the study that contributed the most weight to this analysis.

## BACKGROUND

### Description of the condition

Heart failure is a term used to describe the state that develops when the heart cannot maintain adequate cardiac output, or can do so only at the expense of an elevated filling pressure (Boon 2006; Savarese 2017). Heart failure may be acute or chronic, and can be caused by a variety of conditions, including ischaemic heart disease (coronary artery disease), hypertension, elevated blood pressure, diseases of the heart valves, cardiomyopathy, and congenital heart diseases (Drexler 2004; Ho 1993; Richardson 1996; Teerlink 1991). The most commonly used classification system to quantify the degree of heart failure-associated functional limitation was first developed by the New York Heart Association (NYHA; (NYHA 1964)). This system assigns people to one of four functional classes, depending on the degree of effort needed to elicit symptoms:

- class I – symptoms of heart failure only at activity levels that would limit normal individuals;
- class II – symptoms of heart failure with ordinary exertion;
- class III – symptoms of heart failure with less than ordinary exertion;
- class IV – symptoms of heart failure at rest.

It is now appreciated that heart failure often occurs with preserved left ventricular systolic function (Redfield 2016). Various studies estimate that as many as 40% to 60% of people with heart failure have diastolic dysfunction, as defined by a preserved left ventricular ejection fraction (Elesber 2001; Gottdiener 2002). Thus, heart failure can be classified as ejection fraction reduced, ejection fraction mid-range, and ejection fraction preserved (Ponikowski 2016).

There are at least 26 million people who have heart failure worldwide (Savarese 2017). It is estimated that 6.2 million Americans older than 20 years of age had heart failure between 2013 and 2016, compared to 5.7 million between 2009 and 2012 (Virani 2020). The prevalence of heart failure in the USA is expected to increase from 2.42% in 2012 to 2.97% in 2030 (Virani 2020).

Chronic heart failure is a common condition, and is one of the most frequent causes of disability and admission to hospital in older individuals (Lippi 2020; Savarese 2017). The prevalence of heart failure increases with age, and is associated with high morbidity and mortality worldwide (Rodriguez 2004; Savarese 2017). Based on European data, the 12-month all-cause mortality rate was 17% of hospitalised people with stable heart disease, and 7% in ambulatory people with heart disease, despite major advances in drug treatments (Ponikowski 2016). American data showed even higher mortality rates (Virani 2020).

People with chronic heart failure commonly experience a relapsing and remitting disease course, with periods of stability and episodes of decompensation that lead to worsening symptoms that necessitate hospitalisation. The clinical picture depends on the nature of the underlying heart disease, the type of heart failure that it has evoked, and the neural and endocrine changes that have developed (Boon 2006).

### Description of the intervention

Coenzyme Q10, or ubiquinone, is a non-prescription nutritional supplement. It is a fat-soluble molecule that acts as an electron carrier in mitochondria, and as a coenzyme for mitochondrial enzymes (Gutierrez-Mariscal 2019; Raizner 2019). Coenzyme Q10 is obtained through both tissue synthesis and diet (Raizner 2019). Supplementary oral administration of coenzyme Q10 has been found to increase coenzyme Q10 levels in plasma, platelets, and white blood cells (Niklowitz 2007). Absorption of dietary coenzyme Q10 is slow and limited because of its hydrophobicity and large molecular weight. Solubilised coenzyme Q10 formulations show enhanced bioavailability, with a T<sub>max</sub> (time to reach maximum concentration) of approximately six hours, and an elimination half-life of approximately 33 hours. Oral preparations of coenzyme Q10 are used in human therapeutics (Bhagavan 2007).

Coenzyme Q10 is considered a cell membrane stabiliser, and thought to be useful in preventing atherosclerosis, abnormal protein synthesis, and age-related degenerative diseases (Migliore 2004). Coenzyme Q10 deficiency may be associated with a multitude of diseases, as diverse as coronary artery disease and congestive heart failure, Parkinson's disease, diabetes, breast cancer, and hypertension (Niklowitz 2007).

Coenzyme Q10 appears to be generally safe, with no significant side effects. Potential adverse effects include abdominal discomfort, headache, nausea, vomiting, and allergic maculopapular rash (Baggio 1994; Singh 1999). Coenzyme Q10 may reduce the effectiveness of warfarin, and may limit or prevent effective anticoagulation (Heck 2000).

Some drugs can cause depletion of coenzyme Q10, such as statins (Berthold 2006; Folkers 1990; Mortensen 1997), and beta-blockers (Kishi 1977).

### How the intervention might work

Emerging data suggest that oxidative stress is increased in people with heart failure, and may predict outcome. Markers of oxidative stress have been shown to be elevated in people with both ischaemic and non-ischaemic cardiomyopathy (McMurray 1990; McMurray 1993), to be inversely correlated with the left ventricular ejection fraction (Belch 1991), and directly correlated with the chronicity and severity of heart failure (Diaz-Velez 1996; Nishiyama 1998), and to predict mortality in people with heart failure (Tsutsui 2002). Coenzyme Q10 may reduce oxidative stress because of its antioxidant activity (Rauchova 1995), which has been shown to be similar to that of vitamin E (Tappel 1972). In addition, Coenzyme Q10 supplementation in animal models ameliorated left ventricular dysfunction, decreased left ventricular fibrosis, and improved endothelial function by enhancing nitric oxide bioavailability (De Blasio 2015; Tsai 2012).

Besides preventing oxidative stress in heart failure, coenzyme Q10 may also have a role in stabilising myocardial calcium-dependent ion channels, and in preventing the consumption of metabolites essential for adenosine-5'-triphosphate (ATP) synthesis (Greenberg 1990). Plasma concentration of coenzyme Q10 was found to be an independent predictor of mortality in a cohort of participants with congestive heart failure (Molyneux 2008). Moreover, coenzyme Q10 myocardial tissue levels in people with chronic heart failure, are on average 33% lower than in a control population (Mortensen 1990;

(Mortensen 1993). The severity of heart failure correlates with the severity of coenzyme Q10 deficiency (Mortensen 1984). Therefore, supplementing this deficiency may play a role in the treatment of heart failure.

### Why it is important to do this review

Despite the suggested potential benefits, the quality of evidence for the use of coenzyme Q10 in the treatment of heart failure has not been determined, and it is not included in American or European management guidelines for heart failure (Ponikowski 2016; Yancy 2017). This review is important because it summarises the best available evidence for the safety and efficacy of coenzyme Q10 in people with heart failure. The information derived from this review could assist clinicians and heart associations to determine whether to recommend coenzyme Q10 for heart failure.

An updated review to add new published trials and GRADE analysis is needed to reassess the safety and effectiveness of coenzyme Q10 in heart failure.

### OBJECTIVES

To review the safety and efficacy of coenzyme Q10 in heart failure.

### METHODS

#### Criteria for considering studies for this review

##### Types of studies

We included all randomised controlled trials (RCT) that assessed the beneficial and harmful effects of coenzyme Q10 in heart failure. Cluster-randomised clinical trials (cRCTs) were eligible for inclusion. We placed no restrictions on blinding, publication status, abstracts, conference proceedings, or language. We excluded quasi-randomised and observational studies. When we identified cross-over studies, we only considered data from the first phase. When first-phase data were not available, we contacted the authors to obtain these data, if possible.

##### Types of participants

- We included all participants, regardless of age, with chronic heart failure, defined as a clinical syndrome characterised by breathlessness and fatigue, which was caused by an inability of the heart to support adequate circulation, which may limit exercise tolerance, and may lead to pulmonary congestion and peripheral oedema; also, if possible, defined by more objective evidence of left ventricular systolic or diastolic function (e.g. echocardiography, radionuclide ventriculography, cardiac magnetic resonance, cardiac catheterization, and biomarkers, such as brain natriuretic peptide (BNP), and N-terminal pro-brain natriuretic peptide (NT-proBNP).
- We included participants with ejection fraction reduced heart failure, ejection fraction mid-range heart failure, and ejection fraction preserved heart failure.
- We included participants with chronic heart failure of any severity.
- Chronic heart failure included left-sided and right-sided heart failure.
- We excluded participants with acute heart failure, defined as rapid onset or worsening of sign, symptoms, or both, of heart failure (Ponikowski 2016).

- We included any studies in which the majority of participants met our inclusion criteria, We asked the trial authors for data for the subgroup of interest, and (if no data forthcoming) used sensitivity analysis to investigate the impact of including studies in which not all participants met the inclusion criteria.

##### Types of interventions

- Coenzyme Q10 versus placebo
- Coenzyme Q10 versus another active agent for use in heart failure
- High-dose versus low-dose coenzyme Q10

##### Types of outcome measures

We used all outcome data from the longest follow-up. We did not base our decision to include or exclude the study solely on the reporting of our outcomes of interest. When a published report did not appear to report one of these outcomes, we accessed the trial protocol and contacted the trial authors to ascertain whether the outcomes were measured but not reported. We included relevant trials, which measured these outcomes but did not report the data at all, or not in a usable format, in the review as part of the narrative.

##### Primary outcomes

- All-cause mortality
- Cardiovascular (CV) mortality
- Fatal and non-fatal myocardial infarction
- Fatal and non-fatal stroke
- Revascularisation procedures (percutaneous coronary intervention (PCI) and coronary artery bypass grafting (CABG))
- Hospitalisation due to heart failure (number of people with at least one hospitalisation due to heart failure)
- All-cause hospitalisation (number of people with at least one hospitalisation for any cause)
- New York Heart Association (NYHA) classification of clinical status (four classes, lower = better)

##### Secondary outcomes

- Left ventricular ejection fraction, determined by echocardiography, contrast, or radionuclide angiography
- Symptom improvement, measured by individual trials, by exercise capacity (exercise duration or walking distance, or both), or both
- Other exercise variables (peak  $VO_2$ , exercise haemodynamics)
- Quality of life
- BNP and NT-pro BNP
- Measurement of post-therapeutic serum levels of coenzyme Q10
- Adverse events (number of people with at least one adverse event)
- Cost-effectiveness

##### Search methods for identification of studies

##### Electronic searches

We updated the searches from 2013 on 16 October 2020. We searched the following databases:

- The Cochrane Central Register of Controlled Trials (CENTRAL, 2020 Issue 10), in the Cochrane Library (searched 16 October 2020);
- Epub Ahead of Print, In-Process & Other Non-Indexed Citations, MEDLINE Daily and MEDLINE Ovid (1946 to 15 October 2020);
- Embase Ovid (1980 to 2020 week 41);
- Web of Science Clarivate Analytics (1900 to 16 October 2020);
- CINAHL Plus EBSCO (1981 to 16 October 2020);
- AMED Ovid (Allied and Complementary Medicine; 1985 to October 2020).

We also searched the following clinical trials registers for ongoing or unpublished studies:

- International Standard Randomised Controlled Trial Number Registry (ISRCTN; [www.isrctn.com/](http://www.isrctn.com/); searched 11 November 2019);
- ClinicalTrials.gov ([clinicaltrials.gov/](http://clinicaltrials.gov/); searched 16 July 2020).

The RCT filter for MEDLINE is the Cochrane sensitivity-maximising RCT filter, and for Embase, we applied the terms recommended in the Cochrane *Handbook for Systematic Reviews of Interventions* (Lefebvre 2011). For CINAHL, we used an adaptation of the Cochrane RCT filter. We applied no language restrictions. Searching the World Health Organization (WHO) International Clinical Trials Registry Platform (ICTRP) was not possible, as the database was not available. The search strategies are in [Appendix 1](#).

### Searching other resources

We checked the bibliographic references of the included randomised controlled trials to find randomised controlled trials not identified by the electronic searches. When possible, we approached the principal authors of the identified randomised controlled trials and enquired if they knew of any other randomised controlled trials.

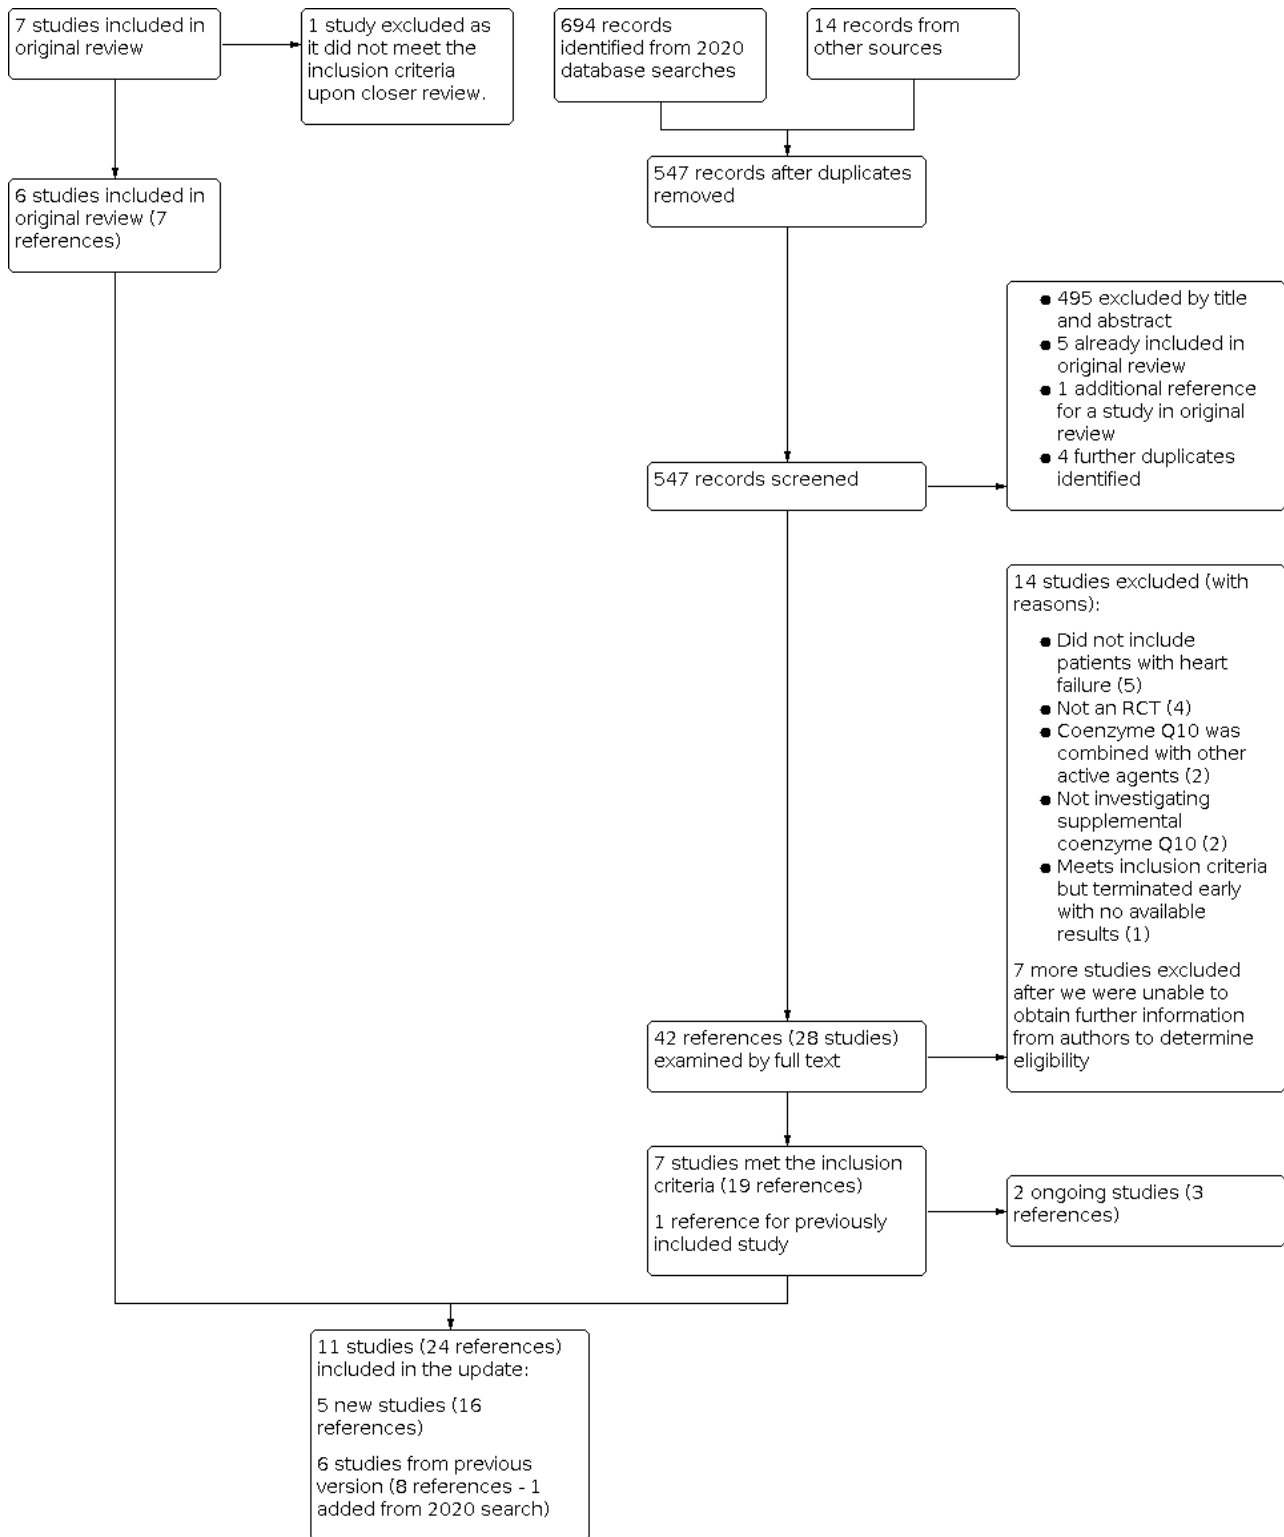

### Data collection and analysis

We conducted the meta-analyses according to Cochrane recommendations (Higgins 2019), using Review Manager 5.4 (Review Manager 2020).

### Selection of studies

Five authors (KT, BS, AM, MK, MF) independently assessed the identified references to determine if they fulfilled the inclusion criteria (two authors per reference). First, we screened the references by title, abstract, or both, and excluded those which were clearly not relevant to the review. Then, we obtained the full texts for the references that passed the first screening phase, and evaluated them for inclusion. In cases when references did not have sufficient information to determine their eligibility, we contacted the trial authors, asking for more information; if we did not receive a response, we excluded these studies. We listed the excluded trials with the reasons for exclusion. We resolved disagreements by discussion. We summarised the flow of papers through the search and selection process using a PRISMA flow chart (Figure 1; Moher 2009).

**Figure 1. PRISMA flow chart**

**Data extraction and management**

Five authors (KT, BS, AM, MK, MF) independently extracted data (two authors per trial), and resolved disagreements by discussion. We used a standardised data collection form to extract data on methods, participants, interventions, and outcomes. If we

identified more than one publication on a single randomised controlled trial, we extracted the most appropriate data.

We extracted data needed to assess risk of bias, conduct meta-analysis, and investigate any possible heterogeneity. The extracted data included data about study methodology (design,

duration, setting, inclusion and exclusion criteria, comparisons groups, randomisation, blinding), participants (total number, demographics, medical conditions), intervention (dose, route, preparation), control (placebo versus active compounds, dosing), outcomes (primary and secondary, outcome measures, time points measured), and funding.

### Assessment of risk of bias in included studies

We assessed methodological quality according to our level of confidence that the design and report of a published trial restricted bias in the intervention comparison (Moher 1998). In assessing the risk of bias, we used the Cochrane tool for assessing risk of bias, described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011). We assessed risk of bias in the following domains: random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessors, incomplete outcome data, selective reporting, and other biases.

### Measures of treatment effect

#### Dichotomous data

We reported absolute effect and risk ratios (RR), with 95% confidence intervals (CI). We calculated the the number needed to treat for an additional beneficial outcome (NNTB), and the number needed to treat for an additional harmful outcome (NNTH), if possible.

#### Continuous data

We calculated mean differences (MD) with 95% CIs for outcomes reported with the same measure. If the quality of life outcome was reported using different tools in different studies, we had planned to use the standardized mean difference (SMD).

### Unit of analysis issues

When we retrieved cross-over studies from the search, we only took the first arm into consideration.

We used all outcome data from the longest follow-up, as mentioned above.

We used guidelines from the *Cochrane Handbook for Systematic Reviews of Interventions* guidelines to inform the inclusion and analysis of cRCTs in our review (Higgins 2011). When analysing results from cRCTs, we had planned to adjust for clustering to avoid artificially narrow confidence intervals for the treatment effect. We also planned to estimate the intracluster correlation coefficient (ICC) to quantify the extent to which data from observations from the same cluster were correlated. However, we did not identify any relevant cluster-randomised trials.

We handled trials with more than one comparison (e.g. two doses of coenzyme Q10 versus placebo or coenzyme Q10 versus another treatment versus placebo), by splitting the shared group (placebo in the first example and coenzyme Q10 in the second) into two or more groups with smaller sample size, to enable us to include two or more comparisons.

### Dealing with missing data

We performed all analyses on an intention-to-treat basis, using the last reported observed response (carry forward) and including all

participants, regardless of compliance or follow-up. In addition, we planned to perform a 'worst-case scenario' analysis, considering all participants with missing data as treatment failures. We used the Review Manager 5 calculator to calculate missing data, like standard deviation (Review Manager 2020).

### Assessment of heterogeneity

We assessed statistical heterogeneity using a Chi<sup>2</sup> test, and we used the I<sup>2</sup> statistic to quantify inconsistency across included studies (Higgins 2003). We also assessed statistical heterogeneity by visually examining the graphical presentations (forest plots; (Egger 1997)).

### Assessment of reporting biases

We tried to locate the protocol for each included randomised controlled trial. If the protocol was available, we compared its outcomes with those in the published RCT report. If it was not available, we compared the outcomes listed in the methods section of the report with the actual reported results. We planned to use a funnel plot of all included trials to check the presence of publication bias, but there were insufficient trials (Egger 1997).

### Data synthesis

We undertook meta-analysis when there were sufficient data of a suitable type, using Review Manager 5 (Review Manager 2020). When there were too few clinically homogeneous trials for us to perform a meta-analysis, we presented a narrative synthesis.

We used the random-effects model to avoid the risk that the variability between the studies may be exclusively due to a random sampling variation around a fixed effect. Using the random-effects model is also recommended by *Clinical Evidence* (Clinical Evidence).

### Subgroup analysis and investigation of heterogeneity

In cases of significant heterogeneity, we aimed to address it by exploring clinical and methodological variations between the studies. If significant differences were identified, we conducted a subgroup analysis to offer new insights and confirm the effect in the different subgroups. Therefore, we conducted a posthoc subgroup analysis to compare studies without a maximum coenzyme Q10 dose against those with a maximum dose of 200 mg daily. Age and gender were the two subgroups planned for analysis in the protocol; however, we were unable to do so, due to insufficient data.

### Sensitivity analysis

We did not carry out any sensitivity analysis because of the small number of included studies for each outcome.

### Summary of findings and assessment of the certainty of the evidence

We used the GRADE approach to assess the quality of the evidence (Higgins 2019), and GRADEpro GDT ([grade.pro.org](http://grade.pro.org)), to import data from Review Manager 5 (Review Manager 2020), to create a 'Summary of findings' table. This table provides outcome-specific information concerning the overall quality of evidence from each included study in the comparison, the magnitude of effect of the interventions examined, and the sum of available data on all outcomes we rated as important to the care of people with

the disorder and decision-making. We selected the following main outcomes for the 'Summary of findings' table:

1. All-cause mortality
2. Fatal and non-fatal myocardial infarction
3. Fatal and non-fatal stroke
4. Hospitalisation due to heart failure
5. Left ventricular ejection fraction
6. Exercise capacity, measured by treadmill exercise test duration
7. Adverse events

Although important, we did not include NYHA clinical status as available data were exhaustive and non-combinable. We intended to include three comparisons (coenzyme Q10 versus placebo or no coenzyme Q10, coenzyme Q10 versus another active agent, and high dose versus low dose coenzyme Q10). However, the identified studies only compared coenzyme Q10 to placebo or standard care, thus, we only created one, instead of three, 'Summary of findings' table.

## RESULTS

### Description of studies

#### Results of the search

The search and screening in the original review resulted in seven included studies. After reviewing these seven studies, we found that one study did not meet the inclusion criteria, so we excluded it ([Adarsh 2008](#)).

For the update, the initial database search on 16 October 2020 yielded 694 records. We also identified 14 records from other sources (one reference was identified by checking the bibliographic references of the included RCTs; 13 references identified by searching the clinical trials databases). After de-duplication, there were 547 references for screening. We removed 505 records (we excluded 495 references by their title and abstract; 5 references were already included in the original review; 1 reference was an additional report for a study in the original review; we identified 4 further duplicate references). Of the 42 remaining references, we combined those belonging to the same study, resulting in 28 unique studies. We retrieved and examined the full texts for the 28 studies, and excluded 14 studies. For seven studies, we needed usable data and additional information, so we contacted the study authors. However, we did not get a response from the authors, so we excluded these seven studies. Of the seven remaining studies, two studies were ongoing (confirmed by contacting their authors). As a result, we identified five new studies with the updated search.

Including the six studies from the original review, the updated review includes a total of 11 studies. Please refer to the PRISMA flow chart for details on the updated search ([Figure 1](#)).

#### Included studies

This review included 11 randomised controlled trials (RCT) with 1573 participants. Only four studies had relatively large sample sizes (128 in [Zhao 2015](#); 148 in [Mareev 2017](#); 420 in [Mortensen 2014](#); 641 in [Morisco 1993](#)). Sample sizes for the rest of the studies ranged from 20 to 55 participants. Only one study had a cross-over design (from which only first phase data were used; ([Kawashima 2016](#))). All other studies had a parallel design.

Five studies were conducted in Asia ([Berman 2004](#); [Kawashima 2016](#); [Kocharian 2009](#); [Sobirin 2019](#); [Zhao 2015](#)), two studies in Europe ([Morisco 1993](#); [Munkholm 1999](#)), one study in Russia ([Mareev 2017](#)), one in Australia ([Keogh 2003](#)), and one in the USA ([Khatta 2000](#)). One study enrolled participants from Europe, Australia, and Asia ([Mortensen 2014](#)).

All studies were conducted with adults, except [Kocharian 2009](#), which included participants younger than 18 years. In addition, all studies used placebo plus conventional therapy in the control group except for two studies, which used conventional therapy alone ([Sobirin 2019](#); [Zhao 2015](#)).

The daily dose of coenzyme Q10 varied significantly among studies: 30 mg in [Zhao 2015](#); 60 mg in [Berman 2004](#); 150 mg in [Keogh 2003](#); 200 mg in [Khatta 2000](#) and [Munkholm 1999](#); 225 mg in [Mareev 2017](#); 300 mg in [Mortensen 2014](#) and [Sobirin 2019](#); and 400 mg in [Kawashima 2016](#). In [Kocharian 2009](#) and [Morisco 1993](#), participants received 2 mg/kg of coenzyme Q10 daily. In one study, coenzyme Q10 was given in a nasal drop form ([Mareev 2017](#)). In all other included studies, it was given orally.

The follow-up period varied among studies: one month in [Sobirin 2019](#); three months in [Berman 2004](#), [Kawashima 2016](#), [Keogh 2003](#) and [Munkholm 1999](#); and six months in [Khatta 2000](#), [Kocharian 2009](#) and [Mareev 2017](#). [Mortensen 2014](#) reported data at 4 and 26 months, while [Zhao 2015](#) reported data at 6 and 12 months. [Morisco 1993](#) followed participants up to 12 months.

Two studies were partially funded by pharmaceutical companies that manufacture and distribute coenzyme Q10 supplements ([Keogh 2003](#); [Mortensen 2014](#)).

See [Characteristics of included studies](#).

#### Excluded studies

In the original review, out of the 721 papers identified in the search, we excluded 567 early in the selection process because the title was irrelevant to the main area of interest. Of the remaining papers, 139 did not meet one or more of the inclusion criteria. We excluded randomised controlled studies with a cross-over design (which were identified in the original review) later, as their data were unsuitable for analysis.

In the update, we excluded 505 out of 547 references by title, abstract, or both, as they were clearly irrelevant to our review. After combining references belonging to the same study, and assessing the full text, we excluded 14 studies: five studies excluded people with heart failure ([Fedacko 2009](#); [IRCT2015070223018N1](#); [NCT03586414](#); [Rivera 2017](#); [Turk 2013](#)), four studies were not RCTs ([Chen 2017](#); [Chen 2018](#); [JPRN-UMIN000020203](#); [Miyazaki 2013](#)), two studies investigated coenzyme Q10 combined with other active agents ([Johansson 2013](#); [Pourmoghaddas 2014](#)), two studies did not investigate supplemental coenzyme Q10 ([JPRN-UMIN00007695](#); [McMurray 2009](#)), and one study met the inclusion criteria but was terminated early and had no available results ([JPRN-UMIN000027248](#)). We excluded seven more studies, as they had no usable data and their authors did not respond to our queries ([Kukharchik 2016](#); [Kukharchik 2016a](#); [Kukharchik 2017](#); [Kumar 2015](#); [Leonova 2018](#); [Oleg 2016](#); [Saurabh 2014](#)).

When we re-examined the studies included in the original review, we found that one study did not meet the inclusion criteria ([Adarsh](#)

2008). The study did not randomise its participants, and thus, is not an RCT. We deleted the study's findings from the updated review, and added it to the list of excluded studies.

See [Characteristics of excluded studies](#).

### **Ongoing studies**

We identified two ongoing studies ([NCT02779634](#); [Pierce 2018](#)). We contacted authors from both studies; they confirmed that the studies are still ongoing, with no published results yet. Both studies are randomised, blinded, placebo-controlled trials with parallel design. [Pierce 2018](#) also investigates D-ribose supplements and has four arms (placebo only, coenzyme Q10 only, D-ribose only, coenzyme Q10 plus D-ribose). [NCT02779634](#) includes participants with heart failure with preserved ejection fraction, and follows them for 16 weeks. [Pierce 2018](#) also includes participants with heart

failure with preserved ejection fraction, and follows them for 12 weeks.

See [Characteristics of ongoing studies](#).

### **Risk of bias in included studies**

Two review authors independently assessed each of the included studies, and found that there was risk of bias in the included studies (see the 'Risk of bias' tables in the '[Characteristics of included studies](#)' tables). We re-evaluated studies included in the original review for risk of bias.

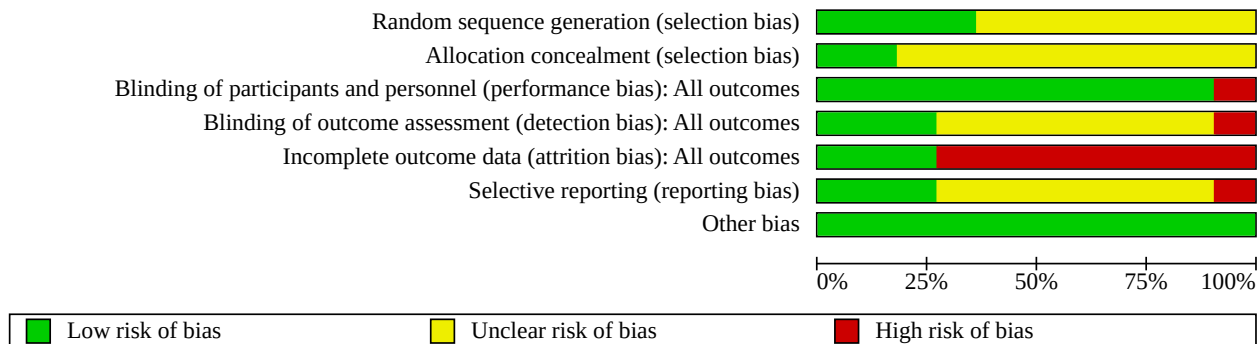

We used the 'Risk of bias' summary and graph figures to illustrate the proportion of studies with each of the judgements (low risk, high risk, unclear risk of bias) for each domain of the tool ([Figure 2](#); [Figure 3](#)).

**Figure 2. 'Risk of bias' summary: review authors' judgements about each 'Risk of bias' item for each included study**

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias): All outcomes	Blinding of outcome assessment (detection bias): All outcomes	Incomplete outcome data (attrition bias): All outcomes	Selective reporting (reporting bias)	Other bias
Berman 2004	?	+	+	?	-	?	+
Kawashima 2016	?	?	+	?	-	+	+
Keogh 2003	?	?	+	?	-	?	+

**Figure 3. 'Risk of bias' graph: review authors' judgements about each 'Risk of bias' item presented as percentages across all included studies**

**Allocation**

All included studies stated they were randomised. However, methods used for random sequence generation were not mentioned in seven studies, and thus, we deemed the risk of selection bias (random sequence generation) in these studies to be unclear (Berman 2004; Kawashima 2016; Keogh 2003; Kocharian 2009; Mareev 2017; Munkholm 1999; Zhao 2015). We assessed the remaining four studies at low risk of bias for random sequence generation.

Nine studies did not mention how they achieved allocation concealment, and therefore, we deemed the risk of selection bias (allocation concealment) to be unclear (Kawashima 2016; Keogh 2003; Khatta 2000; Kocharian 2009; Mareev 2017; Morisco 1993; Munkholm 1999; Sobirin 2019; Zhao 2015). We assessed the remaining two studies at low risk of bias in this domain.

**Blinding**

Only one study was unblinded, and thus, had a high risk of performance bias (Sobirin 2019). All other included studies were double blinded, and thus, we deemed them at low risk of performance bias.

Sobirin 2019 also had a high risk of detection bias, as it was not blinded. Only three studies mentioned that assessors were blinded, and thus, had a low risk of detection bias (Kocharian 2009; Mortensen 2014; Zhao 2015). The rest of the studies did not mention blinding of the assessors, and thus, we deemed them at an unclear risk of detection bias (Berman 2004; Kawashima 2016; Keogh 2003; Khatta 2000; Mareev 2017; Morisco 1993; Munkholm 1999).

**Incomplete outcome data**

In eight studies, some of the participants did not finish the study. They were not included in the analysis. We considered these studies to be at high risk of attrition bias (Berman 2004; Kawashima 2016; Keogh 2003; Khatta 2000; Mareev 2017; Morisco 1993; Sobirin 2019; Zhao 2015). In Munkholm 1999 and Kocharian 2009, all participants completed the trial, therefore, we considered these studies to be at low risk of attrition bias. Mortensen 2014 also had participants who did not finish the study, however, their data were included in the intention-to-treat analysis for the primary outcomes. Trial authors did not find significant differences between groups in the reasons

for withdrawal. Thus, we deemed the risk of attrition bias for this study to be low.

**Selective reporting**

Comparing outcomes reported in the published study was not possible for seven studies, as no published protocols were available (Berman 2004; Keogh 2003; Khatta 2000; Mareev 2017; Morisco 1993; Munkholm 1999; Zhao 2015). Subsequently, we classified the risk of reporting bias as unclear for these studies. We assessed only one study at a high risk of reporting bias, as some of the outcomes listed in the protocol were not reported in the manuscript (Sobirin 2019). We assessed the remaining three studies at low risk of reporting bias.

**Other potential sources of bias**

None reported.

**Effects of interventions**

See: [Summary of findings 1 Coenzyme Q10 compared to placebo or conventional therapy for heart failure](#)

We found no studies that compared coenzyme Q10 to other active agent for heart failure, or compared a high dose to a low dose of coenzyme Q10. All eleven included studies compared coenzyme Q10 to either placebo or conventional therapy. We combined the results from all of the studies into one comparison, coenzyme Q10 versus control, where control referred to placebo plus conventional therapy, or conventional therapy alone.

**Primary outcomes**

Two studies reported on some or all of the following primary outcomes: total mortality, major cardiovascular events, myocardial infarction, stroke, revascularisation procedures, and hospitalisation (Morisco 1993; Mortensen 2014). Seven studies reported on the New York Heart Association (NYHA) functional class (Berman 2004; Kawashima 2016; Keogh 2003; Mareev 2017; Morisco 1993; Mortensen 2014; Munkholm 1999).

In the primary report, Mortensen 2014 reported these outcomes as components of adverse events, and compared them between the two study groups as adverse events rather than as separate outcomes. We extracted these data and directly compared between coenzyme Q10 and control.

### All-cause mortality

One study reported data on mortality ([Mortensen 2014](#)). Coenzyme Q10 (CoQ10) probably reduces all-cause mortality (10% in the intervention group versus 18% in the control group; risk ratio (RR) 0.58, 95% confidence interval (CI) 0.35 to 0.95; one study, 420 participants; [Analysis 1.1](#); moderate-quality evidence) at 106 weeks, and was also superior to control for all-cause mortality survival (hazard ratio (HR) 0.51; 95% CI 0.30 to 0.89;  $P = 0.018$ , as reported by [Mortensen 2014](#)). The number needed to treat for an additional beneficial outcome (NNTB) was 13.3. We downgraded the evidence by one level due to indirectness ([Summary of findings 1](#)).

### Cardiovascular mortality

One study reported data on cardiovascular mortality ([Mortensen 2014](#)). Coenzyme Q10 probably reduces the risk of cardiovascular mortality (9% in CoQ10 group versus 16% in control group;  $P = 0.039$ ) at 106 weeks, with a NNTB of 15. We downgraded the evidence by one level, to moderate quality, due to indirectness.

[Mortensen 2014](#) also reported on major cardiovascular events (defined as unplanned hospital stay resulting from worsening heart failure, cardiovascular death, mechanical assist implantation, or urgent cardiac transplantation). There were fewer cardiovascular events in the coenzyme Q10 group compared to the control group (15% in CoQ10 group versus 26% in control group;  $P = 0.005$ ) at 106 weeks. CoQ10 was also superior to control in time-to-event analysis for cardiovascular events (HR 0.50; 95% CI 0.32 to 0.80;  $P = 0.003$ , as reported by [Mortensen 2014](#)).

### Fatal and non-fatal myocardial infarction

One study reported data on myocardial infarction ([Mortensen 2014](#)). The results were inconclusive for the risk of myocardial infarction between the CoQ10 and control groups (RR 1.62, 95% CI 0.27 to 9.59; one study, 420 participants; low-quality evidence; [Analysis 1.2](#)). We downgraded the quality of the evidence two levels for indirectness and imprecision ([Summary of findings 1](#)).

### Fatal and non-fatal stroke

One study reported data on strokes ([Mortensen 2014](#)). There was little or no difference in the risk of stroke between the CoQ10 and control groups (RR 0.18, 95% CI 0.02 to 1.48; one study, 420 participants; low-quality evidence; [Analysis 1.3](#)). Thus, the results were inconclusive between groups for the risk of stroke. We downgraded the quality of the evidence two levels for indirectness and imprecision ([Summary of findings 1](#)).

### Revascularisation procedures (percutaneous coronary intervention (PCI) and coronary artery bypass grafting (CABG))

One study reported data on revascularisation procedures ([Mortensen 2014](#)). The results were inconclusive between groups for the risk of revascularization procedures compared to control (RR 0.86, 95% CI 0.24 to 3.17; one study, 420 participants; [Analysis 1.4](#)).

### Hospitalisation due to heart failure

Two studies reported data on hospitalisation due to heart failure ([Morisco 1993](#); [Mortensen 2014](#)). Coenzyme Q10 probably reduces hospitalisations due to heart failure when compared to control (RR 0.62, 95% CI 0.49 to 0.78; two studies, 1061 participants;  $I^2 = 0\%$ ; moderate-quality evidence; [Analysis 1.5](#)). The NNTB was 9.7.

It is worth mentioning that those two studies were published more than 20 years apart, and reflect significant changes in medical care and hospitalisation criteria for people with heart failure over this time period. In [Mortensen 2014](#), hospital stays within 30 days of randomisation were not counted. We downgraded the quality of the evidence due to high risk of bias ([Summary of findings 1](#)).

### All-cause hospitalisation

None of the included studies reported on all-cause hospitalisation.

### New York Heart Association (NYHA) classification of clinical status

Seven trials reported on NYHA functional classification ([Berman 2004](#); [Kawashima 2016](#); [Keogh 2003](#); [Mareev 2017](#); [Morisco 1993](#); [Mortensen 2014](#); [Munkholm 1999](#)). They used different methods to report the change in NYHA clinical status, and therefore, we were unable to pool the results.

[Berman 2004](#) reported that the median NYHA class in the coenzyme Q10 group decreased from 3.1 to 2.4, whereas no change was reported in the control group (from median 3.68 to 3.6).

[Keogh 2003](#) reported that the NYHA class in the coenzyme Q10 group showed a small (0.5) but significant ( $P = 0.0001$ ) improvement, whereas the control group showed no significant change. In the coenzyme Q10 group, the NYHA class improved from 2.9 ( $\pm 0.06$ ) to 2.4 ( $\pm 0.12$ );  $P = 0.001$ . The difference in improvement between the coenzyme Q10 group and the control group in mean NYHA class was 0.5, which was statistically significant for the t-test ( $P = 0.012$ ) and for the Wilcoxon test ( $P = 0.02$ ).

[Morisco 1993](#) reported that there was a progressive reduction in the NYHA class in the coenzyme Q10 group, indicating an improvement in functional status that was statistically significant after three, six, and at 12 months. No significant change in functional class was observed in the control group.

[Munkholm 1999](#) reported that the participants in the coenzyme Q10 group tended to improve with respect to their functional class (from 3A to 2B), whereas no improvement was reported in the control group (2B). However, the improvement in the treatment group was not statistically significant.

[Kawashima 2016](#), a cross-over trial, reported data on NYHA functional class, however, they did not provide data separately for the first phase.

[Mortensen 2014](#) reported non-significant improvement in NYHA functional class in both the coenzyme Q10 and control groups at 16 weeks. However, at 106 weeks, a significantly larger proportion of participants in the coenzyme Q10 group showed NYHA functional class improvement compared to the control group (58% versus 45%;  $P = 0.028$ ).

[Mareev 2017](#) reported a greater change of NYHA functional class in the coenzyme Q10 group (NYHA class change -0.16) compared to the control group (-0.08;  $P = 0.033$ ).

### Secondary outcomes

None of the included trials measured quality of life, measured by a recognised scale, exercise variables (exercise haemodynamics), or cost-effectiveness.

### Left ventricular ejection fraction (LVEF)

Eight trials reported on left ventricular ejection fraction (Kawashima 2016; Khatta 2000; Kocharian 2009; Mareev 2017; Mortensen 2014; Munkholm 1999; Sobirin 2019; Zhao 2015). Data from Khatta 2000 were not useable as they did not report standard deviations. Five studies used echocardiography to assess ejection fraction (Kawashima 2016; Kocharian 2009; Mortensen 2014; Sobirin 2019; Zhao 2015). One study used radionuclide ventriculography (Munkholm 1999), and one study used either echocardiography, contrast, or radionuclide ventriculography (Mareev 2017). Two studies reported LVEF at two separate time points (16 and 106 weeks for Mortensen 2014; 6 and 12 months for Zhao 2015), however, we only used the data from the longest follow-up.

Coenzyme Q10 was associated with a small change in LVEF (mean difference (MD) 1.77, 95% CI 0.09 to 3.44; seven studies, 650 participants;  $I^2 = 38\%$ ; very low-quality evidence; Analysis 1.6). We assessed the quality of evidence for this outcome as very low, because of the substantial risk of bias in most of the studies, and the lack of precision, due to the wide confidence intervals (Summary of findings 1). Thus, it is uncertain whether Coenzyme Q10 improves LVEF or not.

### Symptom improvement

Overall, six trials reported on symptom improvement (Berman 2004; Kawashima 2016; Keogh 2003; Khatta 2000; Mareev 2017; Mortensen 2014).

#### Treadmill exercise test duration (seconds)

Three studies reported on exercise capacity, using the duration of treadmill exercise (Kawashima 2016; Keogh 2003; Khatta 2000). Reviewing data from the original version of the review, we found that we had mistakenly switched the numbers for coenzyme Q10 and control groups in the analysis; and input inaccurate numbers of participants in each group for Keogh 2003; and inaccurately converted minutes to seconds for the coenzyme Q10 group in Khatta 2000, although the accurate numbers were not significantly different. We subsequently corrected those numbers for this version.

The results were inconclusive for exercise duration between the coenzyme Q10 and control groups (MD 48.23, 95% CI -24.75 to 121.20; three studies, 91 participants;  $I^2 = 41\%$ ; Analysis 1.7). The sample size for this outcome is very small; it includes studies with high risk of bias; and the effect is imprecise (very wide confidence interval that includes possible harm, no effect, or possible benefit). Thus, the quality of evidence is very low, and it is uncertain whether coenzyme Q10 affects this outcome (Summary of findings 1).

#### Treadmill exercise metabolic equivalents (MET)

One study reported data on exercise capacity using treadmill exercise test metabolic equivalents (METs) (Kawashima 2016). Because this cross-over study did not report analysis for the first phase, we conducted the analysis using data provided by the authors. At three months, the results were inconclusive for METs on the treadmill exercise test between the coenzyme Q10 and control groups (MD -2.51, 95% CI -6.35 to 1.33; one study, nine participants; Analysis 1.8). This effect is imprecise and potentially biased.

### 6-minute walk distance (metres)

Four studies reported on exercise capacity using 6-minute walk test distance (Berman 2004; Keogh 2003; Mortensen 2014, Mareev 2017).

Berman 2004 noted improvement from baseline in the coenzyme Q10 group (269.5 to 382.2 metres;  $P < 0.0001$ ), and deterioration in the control group (254 to 177 metres).

Keogh 2003 found no difference in response between coenzyme Q10 and placebo (an increase of 21 meters in the coenzyme Q10 group, and a decrease of 16 meters in the control group;  $P = 0.29$ ).

Mortensen 2014 reported improvement in the 6-minute walk test in both the coenzyme Q10 and control groups at 16 weeks; the difference between groups was not significantly different.

Mareev 2017 reported improvement in both the coenzyme Q10 (288 to 320 metres;  $P = 0.001$ ) and control groups (311 to 324 metres;  $P = 0.103$ ); as well as in between the two groups ( $P = 0.03$ ).

We could not pool data for the 6-minute walk distance as Berman 2004 and Mareev 2017 did not report standard deviation (SD), and Mortensen 2014 reported only the differences from baseline.

#### Visual analogue scale (VAS)

One study evaluated symptom improvement with a visual analogue scale (VAS) at 16 weeks (Mortensen 2014). It found improvement in both groups; but no difference between groups was found.

#### The Minnesota living with heart failure questionnaire

One study reported on symptom improvement by measuring changes in the Minnesota living with heart failure questionnaire at 24 weeks (Mareev 2017). They found a decrease of 9.1 points in the scores for both the coenzyme Q10 and control groups.

#### The Kansas city cardiomyopathy questionnaire (KCCQ)

One study reported on symptom improvement by measuring changes in the Kansas city cardiomyopathy questionnaire score at 24 weeks (Mareev 2017). There was a larger increase in score for the coenzyme Q10 group (+9.9) compared to the control (+1.4;  $P = 0.034$ ).

#### Other exercise variables – peak oxygen consumption

One study reported data for peak oxygen consumption (Khatta 2000). Data showed an increase in the coenzyme Q10 group and a decrease in the control group; but no significant difference between the two groups.

#### Brain natriuretic peptide (BNP) and N-terminal pro-brain natriuretic peptide (NT-proBNP)

Two studies reported on BNP (Kawashima 2016; Mareev 2017). BNP blood levels were less in the coenzyme Q10 group compared to control (MD -91.97, 95% CI -103.11 to -80.83; two studies, 162 participants;  $I^2 = 0\%$ ; Analysis 1.9).

One study reported on NT-proBNP (Mortensen 2014). It found no difference in change from baseline for NT-proBNP blood levels between the two groups at 16 and 106 weeks.

## Serum levels of coenzyme Q10

Seven studies reported data on coenzyme Q10 serum levels (Berman 2004; Kawashima 2016; Keogh 2003; Khatta 2000; Mareev 2017; Mortensen 2014; Munkholm 1999). We were unable to use data from Berman 2004 as they did not report standard deviations. One study reported coenzyme Q10 serum levels at two separate time points (16 and 106 weeks; (Mortensen 2014)).

Coenzyme Q10 serum levels were higher for those taking the supplement compared to control (MD 1.25, 95% CI 1.09 to 1.42; six studies, 489 participants;  $I^2 = 91%$ ; Analysis 1.10). The high level of heterogeneity was likely due to the differences in coenzyme Q10 levels, caused by different daily coenzyme Q10 regimens administered among the studies. The daily dose of coenzyme Q10 was higher in three studies (400 mg in Kawashima 2016; 300 mg in Mortensen 2014; 225 mg in Mareev 2017), compared to the other studies (150 mg in Keogh 2003; 200 mg in Khatta 2000; 200 mg in Munkholm 1999). Therefore, we conducted a subgroup analysis to compare studies without a maximum coenzyme Q10 dose against those with a maximum dose of 200 mg daily.

### Subgroup analysis

Analysis for studies with doses  $\leq 200$  mg daily continued to show a higher coenzyme Q10 level in those who received coenzyme Q10 compared to the control group (MD 1.46, 95% CI 1.19 to 1.72; three studies, 112 participants;  $I^2 = 29%$ ; Analysis 1.10).

Test for subgroup differences indicated evidence for a difference between effect based on maximum dosage ( $P = 0.04$ ). Heterogeneity, however, remained high in the analysis for studies with dose  $> 200$ mg daily, which is unexplained ( $I^2 = 93%$ ; Analysis 1.10). The effect is inconsistent given the unexplained heterogeneity and potentially biased given the high risk of bias in the included studies.

### Adverse events

Two studies reported on adverse events (Mareev 2017; Mortensen 2014). The results were inconclusive between groups (RR 0.70, 95% CI 0.45 to 1.10; two studies, 568 participants;  $I^2 = 0%$ ; low-quality evidence; Analysis 1.11). We downgraded the quality of the evidence two levels, due to indirectness and imprecision, shown by the wide confidence interval (Summary of findings 1).

### Other cardiovascular outcomes

Morisco 1993 reported that the percentage incidence of acute pulmonary oedema was significantly smaller in the coenzyme Q10 group than in the control group ( $P < 0.001$ ). They also found the incidence of cardiac asthma was lower in participants treated with coenzyme Q10 than those in the control group ( $P < 0.001$ ). The incidence of arrhythmias was higher in the control group than in the coenzyme Q10 group ( $P < 0.001$ ).

## DISCUSSION

### Summary of main results

We included 11 studies comparing coenzyme Q10 to placebo. All had small sample size and all but one study (Kocharian 2009) were performed on adults. Only one of the included studies had a crossover design (Kawashima 2016). Follow up periods varied among the included studies: up to 6 months for 8 studies (Berman 2004; Kawashima 2016; Keogh 2003; Khatta 2000; Kocharian 2009;

Mareev 2017; Munkholm 1999; Sobirin 2019), up to 12 months for two studies (Morisco 1993; Zhao 2015), and 26 months for only one study (Mortensen 2014).

Many of the outcomes were reported by only one of the included studies so no meta-analyses were done. For those outcomes reported by multiple studies, we were not able to combine some of them (NYHA functional class and symptoms improvement in terms of 6-minutes walk test) due to the variability in reporting.

### Primary outcomes

Moderate-level evidence showed that coenzyme Q10 probably reduces the risk of all cause and cardiovascular mortality at 106 weeks (evidence from one study) and hospitalisations for heart failure (evidence from two studies).

Results from individual studies showed lower incidence of acute pulmonary oedema, cardiac asthma and arrhythmia, and fewer cardiovascular events (defined as unplanned hospital stay resulting from worsening HF, cardiovascular death, mechanical assist implantation, or urgent cardiac transplantation) with coenzyme Q10. However results were inconclusive for risk of myocardial infarction, stroke or revascularisation procedures.

Although seven studies reported on NYHA classification, we were unable to pool the results since they used different methods to report the change. Nevertheless, individual studies showed evidence of improvement in NYHA classification with coenzyme Q10.

### Secondary outcomes

Although many studies reported on LVEF, low-quality evidence leaves us uncertain about the effect of coenzyme Q10 on left ventricular ejection fraction (LVEF). The analysis showed improvement in the LVEF with coenzyme Q10, however, the effect size was small and likely not clinically significant (from 0.09% to 3.44% higher).

Overall, coenzyme Q10 was not associated with better outcomes for peak oxygen consumption, the duration of treadmill exercise, treadmill exercise metabolic equivalents, or heart failure symptoms measured on a visual analogue scale and the Minnesota living with heart failure questionnaire. It, however, improves the distance of the 6-minutes walk test and heart failure symptoms measured by the Kansas city cardiomyopathy questionnaire.

Coenzyme Q10 supplements results in higher serum levels of coenzyme Q10, even with a maximum daily dose of 200 mg daily. These findings, however, have significant inconsistency due to unexplained heterogeneity. Furthermore, coenzyme Q10 lowers BNP blood levels; but not lower NT-proBNP. The results for adverse events associated with coenzyme Q10 were inconclusive.

### Overall completeness and applicability of evidence

We were unable to pool the data for most of the outcomes, since they were reported in different ways in different studies, reported in only one study, or not reported in any study. For instance, important outcomes in heart failure (e.g. mortality, cardiovascular events, hospitalisation, adverse events) were rarely investigated. For other important outcomes, like symptom improvement and New York Heart Association classification status, assessment methods and numbers reported varied among studies, limiting our ability to

conduct meta-analyses. The dose of coenzyme Q10 also varied among the studies.

Small sample sizes, short follow up periods and lack of usable data inhibited our ability to pool the data and draw robust conclusions and recommendations for clinical practice. We did not investigate the effect of coenzyme Q10 on several biomarkers, such as C-reactive protein, high sensitivity troponin, myeloperoxidase, and uric acid, as we felt they were less relevant to the objectives of the review. Nevertheless, studying these outcomes in the future might enable a better understanding of the role of coenzyme Q10 in heart failure.

### Quality of the evidence

As noted in the [Risk of bias in included studies](#), most of the included studies had unclear or high risks of bias. There were also multiple pooled outcome measures with wide confidence intervals, often crossing the line of no effect, which we assessed as imprecision. These two factors decreased the quality and certainty of the evidence.

This was evident for five primary outcomes: risk of myocardial infarction, risk of stroke, left ventricular ejection fraction, exercise capacity, and adverse events. We found high levels of heterogeneity for one outcome (serum levels of coenzyme Q10); pooled analysis showed unexplained heterogeneity. Evidence derived from this review ranged from very low to moderate quality. Indeed, this confers the need for larger studies that are clear of risk of evidence evaluating coenzyme Q10.

### Potential biases in the review process

We conducted our review according to a protocol, and following the recommendations of Cochrane. Per the protocol, we used the random-effects model in our analyses. One limitation was the unavailability of data from the first phase of cross-over studies; these data were not published, nor were they provided by the trial authors after we contacted them, except for [Kawashima 2016](#). Therefore, we excluded all cross-over studies except for [Kawashima 2016](#). For variables reported in different ways in different studies, we were unable to pool data. This review combined participants with both heart failure with reduced ejection fraction (HFrEF), and heart failure with preserved ejection fraction (HFpEF). Given the differences in the pathophysiology and treatment of these two types of heart failure, separate analyses for each type would be beneficial in subsequent updates of this review. Finally, there is a lag time between the last search and the publication of this review; it is possible that new trials have been published.

### Agreements and disagreements with other studies or reviews

One meta-analysis concluded that the use of coenzyme Q10 in participants with congestive heart failure improved stroke volume, ejection fraction, cardiac output, cardiac index, and end diastolic volume index ([Soja 1997](#)).

A systematic review with a meta-analysis of studies ranging from 3 to 12 months long, reported non-significant trends towards increased ejection fraction and reduced mortality; they had an insufficient number of participants for meaningful results ([Rosenfeldt 2003](#)).

A systematic review with a meta-analysis concluded that the use of coenzyme Q10 in participants with heart failure improved ejection fraction more in participants who were not receiving angiotensin-converting enzyme inhibitors, and improved cardiac output. Treatment periods ranged from one to six months ([Sander 2006](#)).

A systematic review with a meta-analysis of studies ranging from 4 to 28 weeks long concluded that the use of coenzyme Q10 in participants with congestive heart failure improved ejection fraction, and showed a trend towards improved NYHA functional class that did not reach statistical significance ([Fotino 2013](#)).

Compared to these previous reviews, we are uncertain as to whether the use of coenzyme Q10 in heart failure improves LVEF or not, since the evidence is of very low quality. However, our review shows that coenzyme Q10 in heart failure probably reduces all-cause and cardiovascular mortality. Results in our review are limited by small studies that were at significant risk of bias. Thus, we are unable to draw robust conclusions.

The original Cochrane review concluded that the use of coenzyme Q10 in participants with heart failure did not have an effect on mortality ([Madmani 2014](#)). However, this was derived from the only study that reported on mortality, which we excluded in the current review, due to lack of randomisation ([Adarsh 2008](#)). The original review also concluded no effect on LVEF. This does not contradict the current review, since the studies in the original review only reported short-term follow-up.

## AUTHORS' CONCLUSIONS

### Implications for practice

The currently available evidence is not sufficient to draw robust conclusions about the safety and efficacy of coenzyme Q10 in heart failure.

Included studies provide moderate-quality evidence for a probable benefit for coenzyme Q10 in reducing all-cause mortality, cardiovascular mortality, and hospitalisation for heart failure. The results were inconclusive for risk of myocardial infarction, stroke, or revascularisation procedures.

With very low-quality evidence, it is very uncertain whether coenzyme Q10 has an effect on left ventricular ejection fraction or exercise capacity. Coenzyme Q10 may raise serum levels of coenzyme Q10, however, there is significant heterogeneity. Coenzyme Q10 appeared to lower BNP but not NT-proBNP blood levels. For adverse events, there is a low-quality evidence that coenzyme Q10 may result in possible harm, or little to no difference.

### Implications for research

There is a need for high quality, randomised controlled trials with large sample size, comparing coenzyme Q10 to placebo. Such studies should focus on long-term high-yield outcomes, especially mortality, cardiovascular events, hospitalisations, and side effects. It would also be helpful to examine similar doses of coenzyme Q10, and unified measures of treatment effects across the studies to allow for meta-analyses. Comprehensive reporting of the results of such studies is also key.

## ACKNOWLEDGEMENTS

We are grateful for peer review by Christopher M Florkowski and Taher Entezari-Maleki.

**CHARACTERISTICS OF STUDIES**
**Characteristics of included studies [ordered by study ID]**

**Berman 2004**
**Study characteristics**

Methods	RCT with parallel design
Participants	32 participants with end-stage heart failure awaiting heart transplantation were randomly allocated to receive 60 mg U/day of ultrasome coenzyme Q10 or placebo for 3 months Adults (> 18 years) All participants continued their regular medication regimen
Interventions	Intervention: oral coenzyme Q10 60 mg daily  Control: placebo
Outcomes	Symptoms improvement (NYHA classification)  Symptoms improvement measured on the Minnesota Living with Heart Failure Questionnaire  Quality of life on 6-minute walk test  Blood tests for atrial natriuretic peptide and tumor necrosis factor Echocardiography
Notes	—

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomised, no details about random sequence generation
Allocation concealment (selection bias)	Low risk	Group allocation was done by a third (external) party. Participants were given a personal addressed, sealed envelope containing the words "code A" or "code B"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double-blind
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information given
Incomplete outcome data (attrition bias) All outcomes	High risk	5 participants failed to complete the study because of death, need for heart transplantation, drug-induced intestinal upset, inconvenient travel connections and lack of compliance (1 participant each). Study also did not report the number of participants in the treatment and placebo groups
Selective reporting (reporting bias)	Unclear risk	No study protocol was available.
Other bias	Low risk	No other bias could be found

**Kawashima 2016**
**Study characteristics**

Methods	Randomised double-blinded RCT with cross-over design: participants randomised to coenzyme Q10 or placebo at initiation of study and received therapy for 3 months. They underwent 1-month wash-out period and then participants were crossed over to receive the other therapy (coenzyme Q10 or placebo).
Participants	<p>20 adult participants with chronic heart failure and ejection fraction <math>\leq 40\%</math> as documented with the modified Simpson method via echocardiogram, and who had received standard heart failure treatment for at least 1 month.</p> <p>Excluded: people with malignant disease, severe infectious disease, trauma, people undergoing haemodialysis, and who were receiving other supplements. Some people also excluded based on the decision of the attending doctor.</p>
Interventions	<p>Intervention with dose: oral ubiquinol 200 mg twice daily (400 mg/day)</p> <p>Control: placebo</p>
Outcomes	<p>Used in this review (only from the first phase, at 3 months):</p> <ul style="list-style-type: none"> <li>Levels of coenzyme Q10, Brain natriuretic peptide (BNP) measured by blood test.</li> <li>Exercise capacity measure by exercise duration and METs during treadmill exercise test.</li> <li>Left ventricular ejection fraction measured by echocardiography.</li> </ul> <p>Not used in this review (not outcomes of interest): weight, systolic and diastolic blood pressure, heart rate, white blood cell, haemoglobin, creatinine, eGFR, cystatin-C, total cholesterol, LDL cholesterol, triglycerides, high-sensitivity troponin I, C-reactive protein, urinary 8-OHdG/Cr, CoQ: reduced form, oxidized form, ratio for reduced form to total CoQ10, ratio for reduced form to oxidized form</p> <p>Data about NYHA clinical status from the first phase was not provided by the authors and thus, was not used.</p>
Notes	5 participants dropped out of the treatment group and 1 participant dropped out of the control group. Only 14 out of 20 participants completed the study and were included in the analysis.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Study was mentioned to be randomised, however, random sequence generation method was not mentioned.
Allocation concealment (selection bias)	Unclear risk	Details about allocation concealment were not mentioned.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double blinded
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information about blinding the assessors given.
Incomplete outcome data (attrition bias) All outcomes	High risk	Only 14 out of 20 participants completed the study and were included in the analysis. 5 participants dropped out of the treatment group and 1 participant dropped out of the control group.

**Kawashima 2016** (Continued)

Selective reporting (reporting bias)	Low risk	All outcomes listed in the protocol were reported in the manuscript.
Other bias	Low risk	No other bias could be found.

**Keogh 2003**
**Study characteristics**

Methods	RCT with parallel design
Participants	39 adult participants with NYHA class II or III heart failure were randomised in a double-blind, placebo-controlled study to 150 mg/day of oral coenzyme Q10 or placebo for 3 months 19 participants in the coenzyme Q10 group and 20 in the placebo group Adults (> 18 years)
Interventions	Intervention: oral coenzyme Q10 150 mg/day  Control: placebo
Outcomes	Symptom class by NYHA and specific activities scale  Exercise tolerance by a 6-minute walk test Walk test and treadmill exercise test (modified Naughton stress test) assessment for clinical outcomes of heart failure  Plasma levels of coenzyme Q10  Assessment for the clinical outcomes of heart failure including readmission, transplantation or death, serum creatinine, sodium and potassium
Notes	Study was partially funded by pharmaceutical companies that manufacture and distribute coenzyme Q10 supplements.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomised, no details about random sequence generation mentioned
Allocation concealment (selection bias)	Unclear risk	No information given
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double-blind
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information given
Incomplete outcome data (attrition bias) All outcomes	High risk	In the placebo group, 2 participants withdrew: 1 because of a rash and nausea and the other for epigastric burning with a history of peptic ulceration

**Keogh 2003** (Continued)

In the active group, 1 participant withdrew after 56 days due to increased lethargy and 1 withdrew in order to start carvedilol (prohibited medication)

Selective reporting (reporting bias)	Unclear risk	No study protocol was available.
Other bias	Low risk	No other bias could be found.

**Khatta 2000**
**Study characteristics**

Methods	RCT with parallel design
Participants	55 participants who had congestive heart failure with NYHA class III and IV symptoms to receive either coenzyme Q10 200 mg/day or placebo for a period of 6 months 28 in the treatment group and 27 in the placebo group Adults (> 18 years)
Interventions	Intervention: oral coenzyme Q10 200 mg/day Control: placebo
Outcomes	Left ventricular ejection fraction (measured by radionuclide ventriculography) Peak oxygen consumption
Notes	—

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation was performed using a random number generator
Allocation concealment (selection bias)	Unclear risk	No information given
Blinding of participants and personnel (performance bias) All outcomes	Low risk	All participants and study personnel were blinded to study group assignment until all data were final Double-blind
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information given
Incomplete outcome data (attrition bias) All outcomes	High risk	9 participants did not finish the study: 5 in the coenzyme Q10 group and 4 in the placebo group.
Selective reporting (reporting bias)	Unclear risk	No study protocol was available.
Other bias	Low risk	No other bias could be found

**Coenzyme Q10 for heart failure (Review)**

**Kocharian 2009**
**Study characteristics**

Methods	RCT with parallel design
Participants	38 participants younger than 18 years with idiopathic dilated cardiomyopathy were assigned to receive either coenzyme Q10 or placebo for a period of 6 months  17 participants in the coenzyme Q10 group and 21 in the placebo group Children (< 18 years)
Interventions	Intervention: oral coenzyme Q10 2 mg/kg/day in 2 or 3 divided doses, these being increased to the maximum dose of 10 mg/kg/day according to tolerance or the appearance of side effects  Control: placebo
Outcomes	Left ventricular ejection fraction
Notes	This is the only study that evaluated the use of coenzyme Q10 in children

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomised, no details about random sequence generation provided.
Allocation concealment (selection bias)	Unclear risk	No information given
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double-blind
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Assessors were blinded
Incomplete outcome data (attrition bias) All outcomes	Low risk	All participants completed the trial
Selective reporting (reporting bias)	Low risk	All outcomes listed in the protocol were reported in the manuscript.
Other bias	Low risk	No other bias could be found

**Mareev 2017**
**Study characteristics**

Methods	double-blinded, randomised controlled clinical trial with parallel design
---------	---

**Mareev 2017** (Continued)

Participants	148 participants with heart failure NYHA functional class I to IV and LVEF < 45% who were on optimal medical therapy. Randomisation ratio was 2:1  101 participants in the coenzyme Q10 group and 47 participants in the placebo group
Interventions	Intervention with dose: coenzyme Q10 nasal drops (90 mg/day = equivalent 225 mg/day for liposoluble tablets)  Control: placebo
Outcomes	All outcomes measured at 24 weeks  dynamics of NYHA functional class, The Minnesota Living with Heart Failure Questionnaire, the Kansas City Cardiomyopathy Questionnaire, distance of 6-minute walking test, LVEF, brain natriuretic peptide level, coenzyme Q10 levels, adverse events
Notes	300 participants were initially included in the study, 152 of them failed to follow up and were excluded from the analysis.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Random sequence generation method was not mentioned
Allocation concealment (selection bias)	Unclear risk	Details about allocation concealment were not mentioned
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double-blinded
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information about blinding the assessors given
Incomplete outcome data (attrition bias) All outcomes	High risk	Of 300 enrolled participants, 152 participants were excluded as they failed to follow up; only 148 participants were included in the analysis
Selective reporting (reporting bias)	Unclear risk	No study protocol was available
Other bias	Low risk	No other bias could be found

**Morisco 1993**
**Study characteristics**

Methods	RCT with parallel design
Participants	641 adult (> 18 years) participants with NYHA III or IV heart failure  319 participants in the coenzyme Q10 group and 322 in the placebo group

**Coenzyme Q10 for heart failure (Review)**

**Morisco 1993** (Continued)

Interventions	Intervention: coenzyme Q10 50 mg twice or 3 times daily Control: placebo
Outcomes	NYHA clinical status Incidence of severe cardiovascular complications (pulmonary oedema, cardiac asthma, arrhythmia) Length of hospitalisation
Notes	

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated allocation
Allocation concealment (selection bias)	Unclear risk	Details about allocation concealment were not mentioned
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double-blind
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information given
Incomplete outcome data (attrition bias) All outcomes	High risk	37 participants dropped out in the treatment group and 41 dropped out in the placebo group
Selective reporting (reporting bias)	Unclear risk	No study protocol was available
Other bias	Low risk	No other bias was found

**Mortensen 2014**
**Study characteristics**

Methods	Randomized, double-blinded RCT with parallel design with short-term (16 weeks) and long-term (106 weeks) follow-up
Participants	420 adult participants with heart failure were randomised. Inclusion criteria: chronic heart failure in NYHA functional class III or IV with stable HF therapy Exclusion criteria: myocardial infarction, unstable angina pectoris, percutaneous coronary intervention, cardiac resynchronisation device, cardiac surgery, or stroke, all within 6 weeks of enrolment; HF from congenital heart disease; uncorrected valvular heart disease or planned valve surgery; planned other cardiac surgery or resynchronisation therapy; on urgent waiting list for heart transplantation (status 1 person); implanted mechanical assist device; on continuous inotropic support for HF; restrictive or hypertrophic cardiomyopathy; alcoholic heart disease; acute inflammatory myocarditis; severe

**Coenzyme Q10 for heart failure (Review)**

**Mortensen 2014** (Continued)

non-cardiac disease including malignancy with life expectancy < 1 year; psychosocial instability or anticipated problems with compliance; women of childbearing potential and lactating women; allergy to the constituents of the test medication; supplementary Coenzyme Q10 intake within the last month before run-in; 6-minute walk distance > 450 metres at run-in; participation in another controlled trial

202 participants randomised to coenzyme Q10 group and 218 participants to the placebo group

Interventions	Intervention with dose: oral coenzyme Q10 100 mg 3 times a day with standard HF therapy  Control: placebo with standard HF therapy.
Outcomes	Used in this review: all-cause mortality (at 106 weeks); cardiovascular mortality (at 106 weeks); major adverse cardiovascular events (at 106 weeks); myocardial infarction (at 106 weeks); stroke (at 106 weeks); revascularisation procedures percutaneous intervention and coronary artery bypass grafting (at 106 weeks); hospitalisation due to heart failure (at 106 weeks); left ventricular ejection fraction (at 16 and 106 weeks); symptoms improvement: NYHA, visual analogue scale score, 6-minutes walk test (at 16 and 106 weeks); N-terminal pro-brain natriuretic peptide (NT-proBNP; at 16 and 106 weeks); serum levels of coenzyme Q10 (at 16 and 106 weeks); adverse events (at 106 weeks).  Not used in this review (not outcomes of interest): heart rate, systolic and diastolic blood pressure, left ventricular end systolic and end diastolic pressure (at 16 and 106 weeks)
Notes	36 participants (22 in the coenzyme Q10 group and 14 in the placebo group) withdrew from the study; however, were included in the intention-to-treat analysis. 8 participants (4 in each group) were lost to follow-up at the end of the study period. Intention-to-treat analysis was used for all-cause mortality, cardiovascular mortality, hospitalisations, and adverse events (including revascularisation procedures, strokes, and MI). Study was partially funded by pharmaceutical companies that manufacture and distribute coenzyme Q10 supplements.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Study was randomised. Random sequence generation method was detailed in the methods section.
Allocation concealment (selection bias)	Low risk	Random numbers generated for randomisation were kept in sealed envelopes. Randomisation code was unavailable to investigators, participants, or statisticians.
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Study was double-blinded.
Blinding of outcome assessment (detection bias) All outcomes	Low risk	The randomisation code was unavailable to investigators, participants, or statisticians at any time during the study until all data and materials had been collected, all blood samples had been analysed, and statistical analyses had been performed.
Incomplete outcome data (attrition bias) All outcomes	Low risk	36 participants (22 in the coenzyme Q10 group and 14 in the placebo group) withdrew from the study; however, were included in the intention-to-treat analysis. Analysing withdrawal reasons did not show any significant differences between the groups. 8 participants (4 in each group) were lost to follow-up at the end of the study period.
Selective reporting (reporting bias)	Low risk	All outcomes listed in the protocol were reported in the manuscript.

**Mortensen 2014** (Continued)

Other bias	Low risk	No other risk of bias was found.
------------	----------	----------------------------------

**Munkholm 1999**
**Study characteristics**

Methods	RCT with parallel design
Participants	22 adult participants with NYHA II or III heart failure 11 participants in the treatment group and 11 in the placebo group Adults (> 18 years) Before and after the treatment period, a right heart catheterisation was done
Interventions	Intervention: oral coenzyme Q10 100 mg twice daily for 12 weeks Control: placebo
Outcomes	Baseline and post-therapeutic serum levels of coenzyme Q10 Left ventricular ejection fraction NYHA clinical status
Notes	This study is an invasive study investigating the treatment of congestive heart failure

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomised, no information about random sequence generation provided.
Allocation concealment (selection bias)	Unclear risk	No information given
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double-blind
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No information given
Incomplete outcome data (attrition bias) All outcomes	Low risk	All participants completed the study
Selective reporting (reporting bias)	Unclear risk	No study protocol was available
Other bias	Low risk	No other risk of bias was found

**Sobirin 2019**
**Study characteristics**

Methods	unblinded, randomised controlled clinical trial with parallel design
Participants	<p>30 participants with clinical heart failure were randomised.</p> <p>Inclusion criteria: age <math>\geq</math> 45 years, NYHA functional status II to IV, EF <math>\geq</math> 50%, evidence of diastolic dysfunction on non-invasive imaging, and who had received standard heart failure treatment for 4 weeks before the study</p> <p>Exclusion criteria: chronic atrial fibrillation, acute coronary syndrome or coronary revascularisation within 60 days, clinically significant valvular disease, significantly low systolic blood pressure (<math>&lt;</math> 100 mmHg) or high blood pressure, people with a prior LVEF <math>&lt;</math> 40%, known infiltrative cardiomyopathy (e.g. amyloidosis), hypertrophic cardiomyopathy or chronic pericardial disease, dyspnoea or oedema due to non-cardiac causes, such as pulmonary disease, and anaemia (Hb <math>&lt;</math> 8.0 g/dL), inability or refusal to provide informed consent, poor echocardiographic recordings</p> <p>15 participants were randomised to coenzyme Q10 group and 15 participants to the control group</p>
Interventions	<p>Intervention with dose: oral coenzyme Q10 100 mg three times a day + conventional therapy</p> <p>Control: conventional therapy alone</p>
Outcomes	<p>Outcomes measured at 30 days</p> <p>Used in this review: left ventricular ejection fraction measured by echocardiography</p> <p>Not used in this review (not outcomes of interest): parameters for diastolic function (E/e' ratio, medial and lateral e', E velocity, E/A velocity ratio, deceleration t and LAVI), diastolic and systolic left ventricle internal diameter. left ventricular mass index</p>
Notes	1 participant in the treatment group and 1 participant in the control group were lost to follow-up, and were excluded from the analysis

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	study is randomised; randomisation done by permuted blocks with a ratio of 1:1
Allocation concealment (selection bias)	Unclear risk	Details about allocation concealment were not mentioned
Blinding of participants and personnel (performance bias) All outcomes	High risk	Study was unblinded
Blinding of outcome assessment (detection bias) All outcomes	High risk	Study was unblinded
Incomplete outcome data (attrition bias) All outcomes	High risk	Of the randomised participants, 2 participants were not included in the analysis

**Sobirin 2019** (Continued)

Selective reporting (reporting bias)	High risk	Some outcomes listed in the protocol were not reported in the manuscript (plasma malondialdehyde level, quality of life was measured using the Minnesota Living with Heart Failure Questionnaire (MLHFQ))
Other bias	Low risk	No other risk of bias was found

**Zhao 2015**
**Study characteristics**

Methods	Randomized double-blinded RCT with parallel design
Participants	<p>128 consecutive adult participants with non-ischaemic heart failure were randomised.</p> <p>Inclusion criteria: NYHA functional status II to IV, EF &lt; 40%, and who had received standard heart failure treatment for 3 to 6 months before the study.</p> <p>Exclusion criteria: people with atrial fibrillation before the study, renal or liver dysfunction, acute heart failure, acute coronary syndrome, or heart failure of ischaemic origin</p> <p>62 participants randomised to coenzyme Q10 group and 66 participants to the control group.</p>
Interventions	<p>Intervention with dose: oral coenzyme Q10 30 mg/day + conventional therapy</p> <p>Control: conventional therapy alone</p>
Outcomes	<p>All outcomes measured at 6 and 12 months</p> <p>Used in this review: left ventricular ejection fraction measured by echocardiography</p> <p>Not used in this review (not outcomes of interest): incidence of atrial fibrillation, left ventricular end diastolic diameter (LVED) and left atrial end-diastolic diameter, TNF-<math>\alpha</math> and IL-6, high-sensitivity C-reactive protein (hs-CRP), malondialdehyde (MDA).</p>
Notes	14 participants died and 12 participants lost to follow-up and were excluded. Only 102 participants completed the study and were included in the analysis.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Study was mentioned to be randomised, however, random sequence generation method was not mentioned
Allocation concealment (selection bias)	Unclear risk	Details about allocation concealment were not mentioned
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Double-blind
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Physicians, echocardiography staff, laboratory, and the statistician were all blinded to the study.

**Zhao 2015** (Continued)

Incomplete outcome data (attrition bias) All outcomes	High risk	14 participants died and 12 participants lost to follow-up and were excluded. Only 102 participants (of 128 randomised) completed the study and were included in the analysis.
Selective reporting (reporting bias)	Unclear risk	Study protocol could not be located
Other bias	Low risk	No other risk of bias was found.

RCT: randomised controlled trial

### Characteristics of ongoing studies [ordered by study ID]

#### [NCT02779634](#)

Study name	Ubiquinol treatment in participants with heart failure and preserved ejection fraction
Methods	Randomized, triple-blinded (participant, investigator, outcomes assessor), placebo-controlled, parallel trial
Participants	<p>Adults &gt; 50 years old, meeting the following inclusion criteria:</p> <ul style="list-style-type: none"> <li>• Typical signs and symptoms of congestive heart failure (CHF; New York Association Class 2 to 4)</li> <li>• Normal ejection fraction on echocardiography (EF ≥ 50%)</li> <li>• Evidence of diastolic dysfunction on non-invasive imaging (E:e' &gt; 15 or e:e' &gt; 8, with other measures of diastolic dysfunction, such as E/A &lt; 0.5 with elevated deceleration time, or left atrial volume index &gt; 40 cc/m<sup>2</sup>, or presence of elevated left ventricular mass index, or elevated pulmonary pressures)</li> <li>• Stable medical therapy for 4 weeks prior to randomisation</li> </ul>
Interventions	<p>Placebo: sugar pill three times daily</p> <p>Ubiquinol (coenzyme Q10): pills of 100 mg, three times daily</p> <p>Interventions administered for 16 weeks</p>
Outcomes	<ul style="list-style-type: none"> <li>• Change in diastolic function as assessed by mitral valve inflow and tissue Doppler velocities on echocardiography</li> <li>• NT-pro brain natriuretic peptide (NT-proBNP) serum levels</li> </ul> <p>Outcomes assessed at 4 months</p>

**NCT02779634** (Continued)

Starting date	July 2016
Contact information	Sara Elias (sarae@hadassah.org.il) David Leibowitz, MD (oleibo@hadassah.org.il)
Notes	Recruitment done, finishing follow-up

**Pierce 2018**

Study name	Reducing symptom burden in participants with heart failure with preserved ejection fraction using ubiquinol and/or D-ribose
Methods	Randomized, double-blinded (participant, investigator), placebo-controlled, parallel trial
Participants	<p>Adults, 50 years and older, meeting the following inclusion criteria:</p> <ul style="list-style-type: none"> <li>• Diagnosed with heart failure with preserved ejection fraction within a 6-month period</li> <li>• New York Heart Association (NYHA) Classification II to III heart failure</li> <li>• Have left ventricular ejection fraction (EF) <math>\geq</math> 50% documented by an echocardiogram</li> <li>• Have a telephone or reliable phone contact</li> <li>• Have their own means of transportation to the study site</li> </ul>
Interventions	<p>Arm 1 (placebo only): placebo pills that are 300 mg capsules, two times daily plus 15 grams placebo powder, mixed with non-carbonated liquid, one time daily</p> <p>Arm 2 (coenzyme Q10 only): 300 mg capsules of coenzyme Q10, two times daily plus 15 grams placebo powder, mixed with non-carbonated liquid, one time daily</p> <p>Arm 3 (D-ribose only): 15 grams D-Ribose powder, mixed with non-carbonated liquid, one time daily plus placebo pills that are 300 mg capsules, two times daily</p> <p>Arm 4 (coenzyme Q10 + D-ribose): 300 mg capsules of coenzyme Q10, two times daily plus 15 grams D-Ribose powder, mixed with non-carbonated liquid, one time daily</p> <p>Interventions administered for up to 12 weeks</p>
Outcomes	<p>Primary outcomes: change in health status of participants, measured by the Kansas City Cardiomyopathy Questionnaire</p> <p>Secondary outcomes:</p> <ul style="list-style-type: none"> <li>• Change in vigour measured using the Vigor subscale from the Profile of Mood States (POMS) questionnaire</li> <li>• Left ventricular diastolic function</li> <li>• Change in 6-minute walk test</li> <li>• Change in venous blood B-type natriuretic peptide (BNP) levels</li> <li>• Change in lactate/adenosine triphosphate (ATP) ratio</li> </ul>
Starting date	February 5, 2018

**Coenzyme Q10 for heart failure (Review)**

## DATA AND ANALYSES

### Comparison 1. Coenzyme Q10 versus control

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 All cause mortality	1		Risk Ratio (M-H, Random, 95% CI)	Totals not selected
1.2 Myocardial infarction	1		Risk Ratio (M-H, Random, 95% CI)	Totals not selected
1.3 Stroke	1		Risk Ratio (M-H, Random, 95% CI)	Totals not selected
1.4 Revascularisation procedures	1		Risk Ratio (M-H, Random, 95% CI)	Totals not selected
1.5 Hospitalisation for heart failure	2	1061	Risk Ratio (M-H, Random, 95% CI)	0.62 [0.49, 0.78]
1.6 Left ventricular ejection fraction (%)	7	650	Mean Difference (IV, Random, 95% CI)	1.77 [0.09, 3.44]
1.7 Exercise capacity: treadmill exercise test duration (seconds)	3	91	Mean Difference (IV, Random, 95% CI)	48.23 [-24.75, 121.20]
1.8 Exercise capacity: metabolic equivalent on treadmill exercise test (METs)	1		Mean Difference (IV, Random, 95% CI)	Totals not selected
1.9 Brain natriuretic peptide (pg/mL)	2	162	Mean Difference (IV, Random, 95% CI)	-91.97 [-103.11, -80.83]
1.10 Serum levels of coenzyme Q10 (µg/mL)	6	489	Mean Difference (IV, Random, 95% CI)	1.25 [1.09, 1.42]
1.10.1 Studies with coenzyme Q10 dose >200 mg daily	3	377	Mean Difference (IV, Random, 95% CI)	1.13 [0.96, 1.30]
1.10.2 Studies with maximum coenzyme Q10 dose of 200 mg daily	3	112	Mean Difference (IV, Random, 95% CI)	1.46 [1.19, 1.72]
1.11 Adverse events	2	568	Risk Ratio (M-H, Random, 95% CI)	0.70 [0.45, 1.10]

**Analysis 1.1. Comparison 1: Coenzyme Q10 versus control, Outcome 1: All cause mortality**

**Analysis 1.2. Comparison 1: Coenzyme Q10 versus control, Outcome 2: Myocardial infarction**

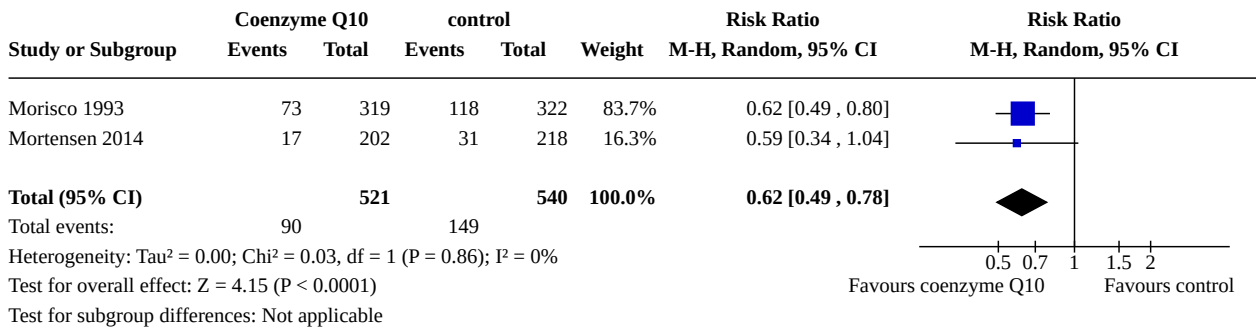

**Analysis 1.3. Comparison 1: Coenzyme Q10 versus control, Outcome 3: Stroke**

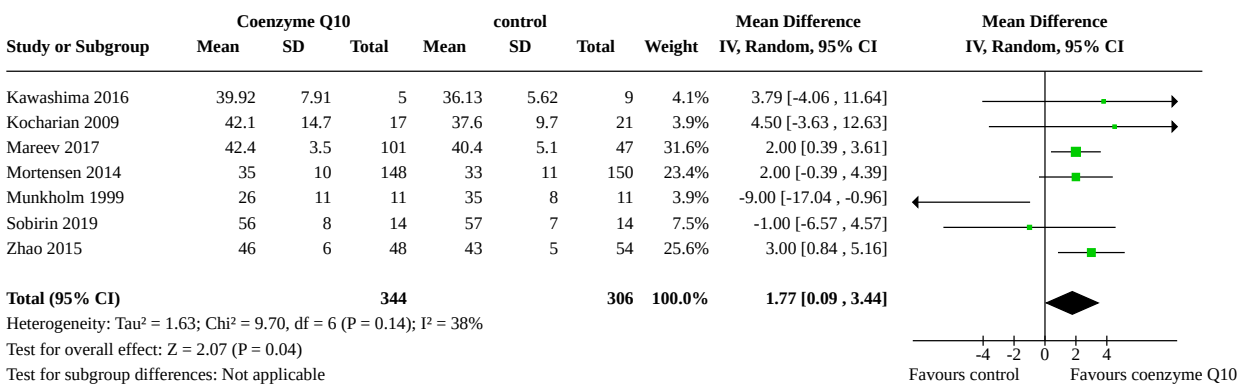

**Analysis 1.4. Comparison 1: Coenzyme Q10 versus control, Outcome 4: Revascularisation procedures**

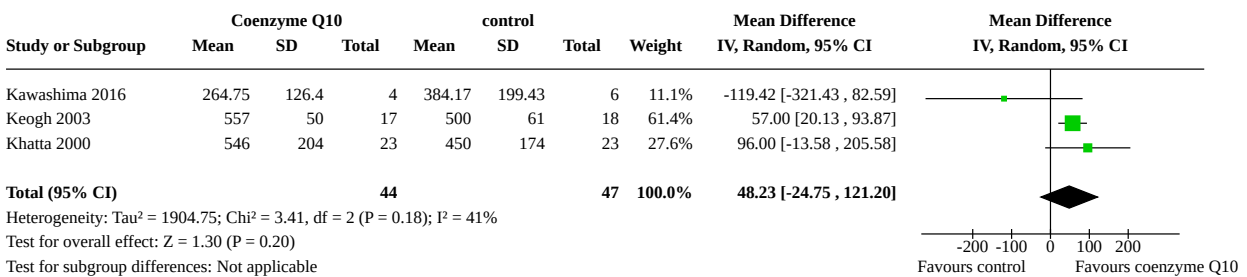

**Analysis 1.5. Comparison 1: Coenzyme Q10 versus control, Outcome 5: Hospitalisation for heart failure**

**Analysis 1.6. Comparison 1: Coenzyme Q10 versus control, Outcome 6: Left ventricular ejection fraction (%)**

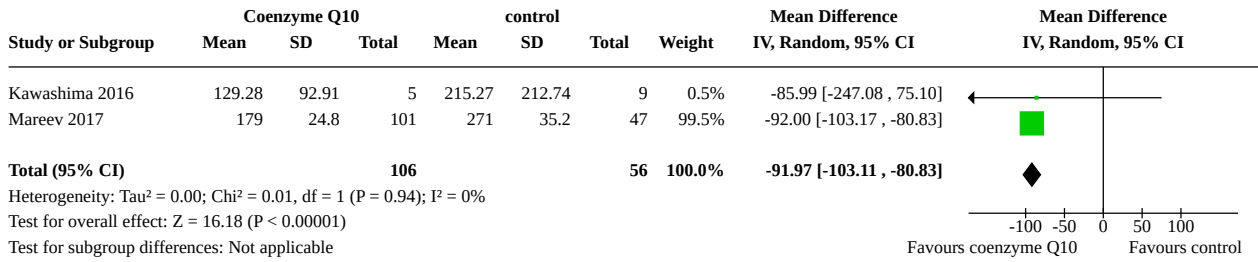

**Analysis 1.7. Comparison 1: Coenzyme Q10 versus control, Outcome 7: Exercise capacity: treadmill exercise test duration (seconds)**

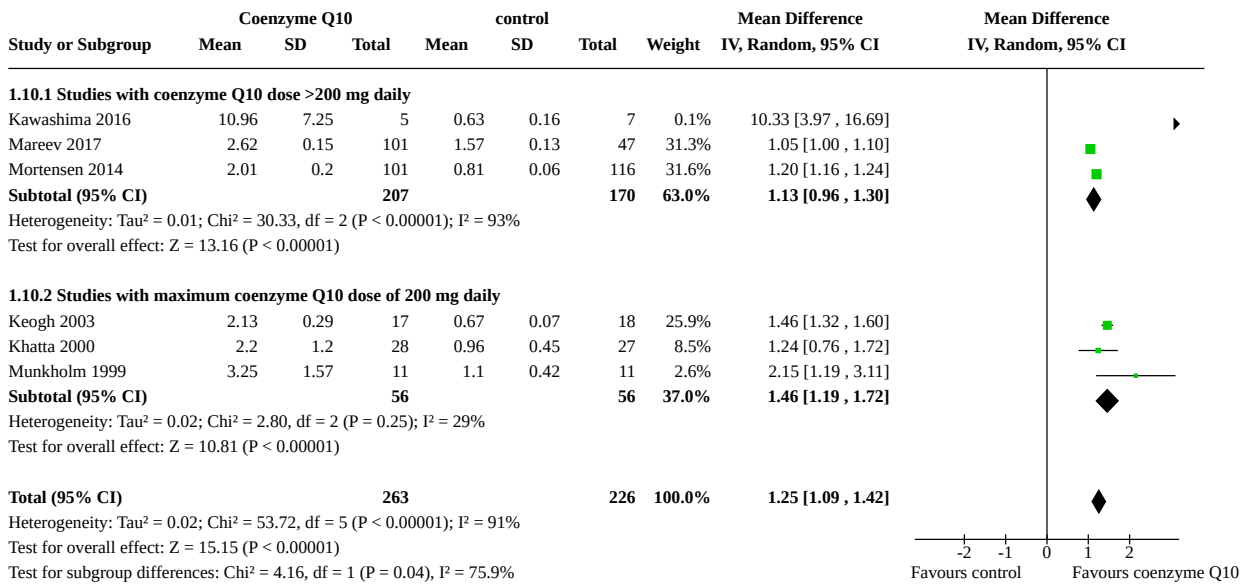

**Analysis 1.8. Comparison 1: Coenzyme Q10 versus control, Outcome 8: Exercise capacity: metabolic equivalent on treadmill exercise test (METs)**

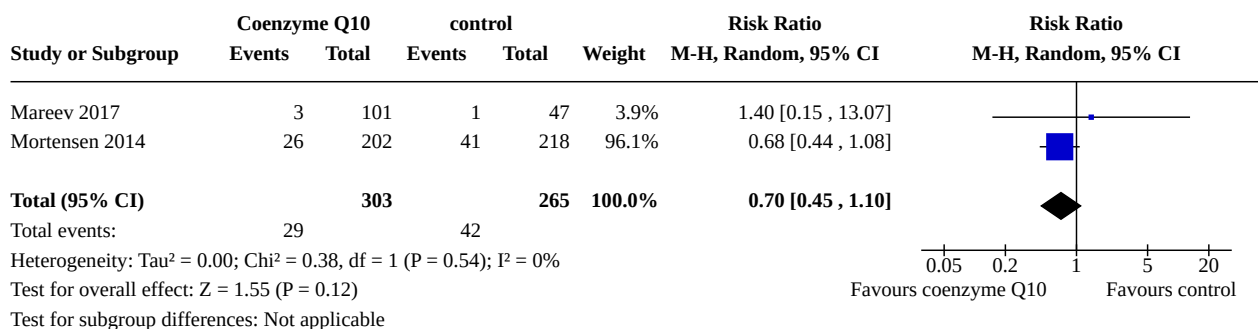

**Analysis 1.9. Comparison 1: Coenzyme Q10 versus control, Outcome 9: Brain natriuretic peptide (pg/mL)**

**Analysis 1.10. Comparison 1: Coenzyme Q10 versus control, Outcome 10: Serum levels of coenzyme Q10 (µg/mL)**

**Analysis 1.11. Comparison 1: Coenzyme Q10 versus control, Outcome 11: Aderse events**

Other terms: "coenzyme Q" OR "Ubiquinone" OR "ubidecarenone" OR "Q10" OR "CoQ10" OR "coenzyme Q" OR "co-enzyme" OR "Q neuquinon" OR "quinone" OR "ubiquinol Q-10"

## WHAT'S NEW

Date	Event	Description
16 October 2020	New citation required and conclusions have changed	Five new studies included, one of the previously included studies removed. Conclusions changed from 'no convincing evidence' to 'moderate evidence of a probable benefit'.
16 October 2020	New search has been performed	Review updated – the evidence is current to 16 October 2020

## HISTORY

Protocol first published: Issue 9, 2010

Review first published: Issue 6, 2014

## CONTRIBUTIONS OF AUTHORS

TA: trial identification, data extraction, 'Risk of bias, assessment, data analysis, 'Summary of findings' table, developed and finalised the protocol and the review.

YA: trial identification, data extraction, 'Risk of bias' assessment, developed and finalised the protocol and the review.

MF: trial identification, data extraction, 'Risk of bias' assessment, drafting the review.

KT: trial identification, data extraction, 'Risk of bias' assessment, 'Summary of findings' table, and drafting the review.

AM: trial identification, data extraction, 'Risk of bias' assessment, drafting the review.

BS: trial identification, data extraction, 'Risk of bias' assessment, drafting the review.

MK: trial identification, data extraction, 'Risk of bias' assessment, drafting the review.

AE: provided methodological support, trial identification, developed and finalised the protocol and the review

MM: provided methodological support, trial identification, developed and finalised the protocol and the review

All authors contributed to, and approved the final version of the review.

## SOURCES OF SUPPORT

### Internal sources

- No sources of support supplied

### External sources

- NIHR Infrastructure Funding, UK

This project was supported by the National Institute for Health Research via Cochrane Infrastructure funding to the Heart Group. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, NHS or the Department of Health and Social Care.

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

In this update, we re-ran searches for all databases listed in the Methods section from 2013. We reassessed studies included in the original review for inclusion, and subsequently excluded one. We also reassessed these studies for risk of bias. We added a 'Summary of findings' table to summarise available data on all outcomes we rated as important to care and decision making. Age and gender were the two subgroups planned for analysis in the protocol; however, this was not possible, due to insufficient data. We conducted a posthoc subgroup analysis to compare studies without a maximum coenzyme Q10 dose against those with a maximum dose of 200 mg daily.

## INDEX TERMS

### Medical Subject Headings (MeSH)

Ataxia; \*Heart Failure [drug therapy]; Mitochondrial Diseases; Muscle Weakness; \*Myocardial Infarction [drug therapy]; Quality of Life; \*Stroke; Stroke Volume; Ubiquinone [adverse effects] [analogs & derivatives] [deficiency]; Ventricular Function, Left

### MeSH check words
