## ABSTRACT

### Background

Souvenaid is a dietary supplement with a patented composition (Fortasyn Connect™) which is intended to be used by people with Alzheimer's disease (AD). It has been designed to support the formation and function of synapses in the brain, which are thought to be strongly correlated with cognitive function. If effective, it might improve symptoms of Alzheimer's disease and also prevent the progression from prodromal Alzheimer's disease to dementia. We sought in this review to examine the evidence for this proposition.

### Objectives

To assess the effects of Souvenaid on incidence of dementia, cognition, functional performance, and safety in people with Alzheimer's disease.

### Search methods

We searched ALOIS, i.e. the specialised register of the Cochrane Dementia and Cognitive Improvement Group, MEDLINE (Ovid SP), Embase (Ovid SP), PsycINFO (Ovid SP), Web of Science (ISI Web of Science), Cinahl (EBSCOhost), Lilacs (BIREME), and clinical trials registries up to 24 June 2020. We also reviewed citations of reference lists of landmark papers, reviews, and included studies for additional studies and assessed their suitability for inclusion in the review.

### Selection criteria

We included randomised, placebo-controlled trials which evaluated Souvenaid in people diagnosed with mild cognitive impairment (MCI) due to AD (also termed prodromal AD) or with dementia due to AD, and with a treatment duration of at least 16 weeks.

### Data collection and analysis

Our primary outcome measures were incidence of dementia, global and specific cognitive function, functional performance, combined cognitive-functional outcomes and adverse events. We selected studies, extracted data, assessed the quality of trials and intended to conduct meta-analyses according to the *Cochrane Handbook for Systematic Reviews of Interventions*. We rated the quality of the evidence using the GRADE approach. We present all outcomes grouped by stage of AD.

### Main results

We included three randomised, placebo-controlled trials investigating Souvenaid in 1097 community-dwelling participants with Alzheimer's disease. One study each included participants with prodromal AD, mild AD dementia and mild-to-moderate AD dementia. We

rated the risks of bias of all trials as low. One study (in prodromal AD) was funded by European grants. The other two studies were funded by the manufacturer of Souvenaid.

One trial investigated the incidence of dementia in people with prodromal AD at baseline, and found little to no difference between the Souvenaid group and the placebo group after 24 months (RR 1.09, 95% CI 0.82 to 1.43; 1 trial, 311 participants; moderate quality of evidence).

In prodromal AD, and in mild and mild-to-moderate Alzheimer's disease dementia, Souvenaid probably results in little or no difference in global or specific cognitive functions (moderate quality of evidence). Everyday function, or the ability to perform activities of daily living, were measured in mild and mild-to-moderate AD dementia. Neither study found evidence of a difference between the groups after 24 weeks of treatment (moderate quality of evidence). Two studies investigated combined cognitive-functional outcomes with the Clinical Dementia Rating Sum of Boxes and observed conflicting results. Souvenaid probably results in slight improvement, which is below estimates of meaningful change, in participants with prodromal Alzheimer's disease after 24 months (moderate quality of evidence), but probably has little to no effect in mild-to-moderate Alzheimer's disease dementia after 24 weeks (moderate quality of evidence).

Adverse effects observed were low in all trials, and the available data were insufficient to determine any connection with Souvenaid.

### Authors' conclusions

Two years of treatment with Souvenaid probably does not reduce the risk of progression to dementia in people with prodromal AD. There is no convincing evidence that Souvenaid affects other outcomes important to people with AD in the prodromal stage or mild-to-moderate stages of dementia. Conflicting evidence on combined cognitive-functional outcomes in prodromal AD and mild AD dementia warrants further investigation. Adverse effects of Souvenaid seem to be uncommon, but the evidence synthesised in this review does not permit us to make a definitive statement on the long-term tolerability of Souvenaid. The effects of Souvenaid in more severe AD dementia or in people with AD at risk of nutritional deficiencies remain unclear.

## PLAIN LANGUAGE SUMMARY

### The dietary supplement Souvenaid for preventing dementia or delaying cognitive decline in people with Alzheimer's disease

#### Review question

We investigated whether people with mild cognitive impairment (MCI) due to Alzheimer's disease (AD) can reduce their risk of developing dementia with a patented dietary supplement called Souvenaid. We also investigated the effect of Souvenaid on memory or other thinking skills, ability to carry out daily activities, and side effects in people with MCI or any stage of dementia due to AD.

#### Background

Alzheimer's disease is a brain disease. It is the commonest cause of dementia among older people. A person is said to have dementia when there has been a decline in their memory and thinking skills which is severe enough to stop them being fully independent in all their daily activities. Because AD develops slowly, it is also possible to pick up symptoms before dementia is fully developed. This pre-dementia stage, when people with AD have a detectable decline in memory and thinking skills but are still able to manage their usual activities independently, is known as mild cognitive impairment due to AD, or 'prodromal' AD.

Souvenaid is a patented mix of vitamins and minerals (Fortasyn Connect™) which was designed to improve brain function in AD. It is a drink which is to be taken once a day. It is intended to be consumed under medical supervision, in addition to the usual diet.

#### Search for evidence

We systematically searched for randomised controlled trials (RCTs) which were published up to June 2020 and which compared treatment with Souvenaid for at least 16 weeks with treatment with a dummy supplement (a placebo). For the comparison to be fair, it had to be decided randomly whether each participant was given Souvenaid or the placebo.

#### Key results

We found three RCTs with a total of 1097 participants to include in the review. Two of the trials investigated Souvenaid in people with dementia over a treatment period of 24 weeks. One of these included 527 participants with mild-to-moderate dementia due to AD and the other included 259 participants with mild dementia due to AD. The third trial investigated the use of Souvenaid for two years in 311 people with prodromal AD.

We considered all of the trials to be well-designed, but because of differences between them in the severity of the participants' symptoms and in the way the researchers measured their results, we were not able to combine the data numerically from the single trials. All the results we report are therefore based on single trials, which leads us to have only moderate confidence in the findings of this review. This means that results could be changed by further research.

We found that people with prodromal AD who took Souvenaid daily for two years were probably no more or less likely than those taking placebo to develop dementia.

Souvenaid probably had little or no effect on measures of memory or other thinking skills in people with prodromal AD (after two years of treatment) or with mild or mild-to-moderate dementia due to AD (after 24 weeks of treatment). It also probably had little or no effect on the ability of people with mild or mild-to-moderate dementia due to AD to manage everyday activities (again after 24 weeks).

Two studies used an outcome scale which combined memory and thinking skills with practical skills (described as a combined cognitive-functional outcome). There was probably a small benefit of Souvenaid on this outcome among people with prodromal AD who took Souvenaid for two years. However, there was probably little or no effect of Souvenaid on this outcome among people with mild-to-moderate AD dementia who took it for 24 weeks.

There were only a few adverse events reported in the trials, and it was not possible to know whether any of them were side effects of Souvenaid.

### **Study funding sources**

Two studies were funded by the manufacturer of Souvenaid. The third study (in prodromal AD) was funded by European grants.

## SUMMARY OF FINDINGS

### Summary of findings 1. Souvenaid compared to placebo for MCI/prodromal AD

#### Souvenaid compared to placebo for MCI

**Patient or population:** People with MCI/prodromal AD

**Setting:** community

**Intervention:** Souvenaid

**Comparison:** placebo

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Nº of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with placebo	Risk difference with Souvenaid				
Incidence of dementia Follow-up: 24 months	Study population		RR 1.09 (0.82 to 1.43)	311 <sup>a</sup> (1 RCT)	⊕⊕⊕⊖ MODERATE <sup>b</sup>	Souvenaid probably results in little to no difference in incidence of dementia
	373 per 1000	34 more per 1000 (67 fewer to 161 more)				
Cognition (global cognitive function) Assessed with: NTB total composite z-score (16 components) Follow-up: 24 months	Single study reported no significant difference between Souvenaid and placebo when missing data were considered in a modified ITT analysis (LME: MD 0.10, 95% CI -0.04 to 0.24), or based on available-case analysis (MD 0.08, 95% CI -0.04 to 0.20) <sup>c</sup>		-	311 <sup>a</sup> (1 RCT)	⊕⊕⊕⊖ MODERATE <sup>b</sup>	Souvenaid probably results in little to no difference in cognition
Memory (specific cognitive function) Assessed with: NTB memory domain z-score (3 components) Follow-up: 24 months	Single study reported no significant difference between Souvenaid and placebo when missing data were considered in a modified ITT analysis (LME: MD 0.14, 95% CI -0.03 to 0.30), or based on available-case analysis (MD 0.13, 95% CI -0.01 to 0.27) <sup>c</sup>		-	311 <sup>a</sup> (1 RCT)	⊕⊕⊕⊖ MODERATE <sup>b</sup>	Souvenaid probably results in little to no difference in memory
Executive function (specific cognitive function) Assessed with: NTB executive function domain z-score (4 components) Follow-up: 24 months	Single study reported no significant difference between Souvenaid and placebo when missing data were considered in a modified ITT analysis (LME: MD -0.04, 95% CI -0.18 to 0.10), or based on available-case analysis (MD -0.11, 95% CI -0.22 to 0.01) <sup>c</sup>		-	311 <sup>a</sup> (1 RCT)	⊕⊕⊕⊖ MODERATE <sup>b</sup>	Souvenaid probably results in little to no difference in executive function

## BACKGROUND

### Description of the condition

The world's population is ageing (United Nations 2017). Improvements in health care in the past century have contributed to people living longer and healthier lives. However, since age is the strongest risk factor for dementia, this has resulted in an increase in the number of people with dementia (WHO 2012, WHO 2019). It is estimated that over 46 million people are currently affected worldwide, resulting in high costs and considerable burden to individuals and societies (Wimo 2015).

The term 'dementia' refers to a syndrome occurring in a group of diseases of typically chronic or progressive nature. It involves disturbances of multiple higher cortical functions, such as memory, thinking, orientation, perception and behaviour, and it affects the ability to perform everyday activities. Deterioration in emotional control, social behaviour, or motivation often precedes or accompanies cognitive decline. The most common form of dementia is due to Alzheimer's disease (AD), which is involved in 60% to 70% of cases. Vascular dementia is also very common. Dementia with Lewy bodies and frontotemporal dementia are less frequent forms. However, mixed forms are frequent and subtypes are indistinct (Prince 2009).

Alzheimer's disease is characterised by the accumulation of misfolded proteins, neuronal dysfunction and cell death in the brain. The deposition of amyloid  $\beta$  peptides in the brain as the central event in Alzheimer's disease pathology has been predominantly discussed over the last decades, but the causative mechanisms of these alterations are still being debated (Andrade-Moraes 2013; Bloom 2014; Querfurth 2010). However, the concomitant dysfunction of synapses, which mediate information transmission, is strongly correlated with cognitive decline and memory dysfunction in Alzheimer's disease (Querfurth 2010). There is also evidence and consensus that this pathophysiological process begins in very early stages of cognitive decline or even before memory symptoms occur (Dubois 2016; Kryscio 2014; Monsell 2014; Scheff 2007). In a hypothetical model of the Alzheimer's disease continuum, this pathophysiological process is also defined as the 'preclinical stage of Alzheimer's disease' which precedes the first signs of mild cognitive impairment (Sperling 2011). Current diagnostic criteria (i.e. Dubois 2014) therefore distinguish between pathophysiological processes and clinically observable syndromes (Jack 2011).

Mild cognitive impairment (MCI) generally describes a condition of intermediate symptomatology between normal cognitive changes of ageing and fully developed symptoms of dementia of all types (Petersen 1999). The term refers to a pre-dementia syndrome where individuals themselves, people who know them well, or clinicians observe a progressive cognitive decline, and there is objective evidence of lower-than-expected performance in one or more cognitive domains. MCI is distinguished from dementia in that the cognitive impairment does not interfere with the ability to function independently at work or in usual daily activities (McKhann 2011). In order to be considered 'MCI due to Alzheimer's disease', the aetiology of MCI should be consistent with the pathophysiological process of Alzheimer's disease, while other causes for cognitive impairment should be ruled out. These core criteria for the diagnosis of MCI due to Alzheimer's disease may be further supported by genetics or biomarkers (Albert 2011).

Although MCI is a risk factor for Alzheimer's disease, we are still not able to predict if and when an individual with MCI might develop Alzheimer's disease dementia (Ritchie 2014; Sperling 2011; Williams 2010).

The term 'prodromal AD', which is used in the diagnostic criteria of the International Working Group (IWG) (Dubois 2007; Dubois 2014), also refers to the pre-dementia stage of AD but is based on objective measures of memory impairment. While biomarker abnormalities may support the diagnosis of MCI due to AD (Albert 2011), they are required for the diagnosis of prodromal AD (Dubois 2014). Similar to MCI, prodromal AD is distinguished from dementia in that the cognitive deficits do not interfere with the usual performance of "accustomed instrumental activities of daily living (IADL)" (EMA 2018). The European Medicines Agency (EMA 2018) stated in recent guidelines that "It is recognized that the clinical characteristics of patients with prodromal AD/MCI due to AD may overlap with those at the milder end of the AD dementia spectrum and that, despite all efforts for criteria harmonization, operationally defined stages of disease are not clearly demarcated". They further suggest that these populations may be studied together (EMA 2018).

The clinical course of dementia due to Alzheimer's disease is often described in progressive stages, although the stages are continuous and there is much variation between individuals in the way the disease presents. The early stages of the disease are typically characterised by forgetfulness, communication problems and difficulties in carrying out complex activities (e.g. finances). In the middle stage, symptoms become increasingly obvious. Memory loss and confusion progress and individuals gradually lose the ability to care for themselves without considerable support. In the late or severe stages individuals are dependent on others for all care (WHO 2019), and psychiatric and behavioural symptoms are very common (WHO 2012).

Currently, medical treatment options for dementia due to Alzheimer's disease are limited to acetylcholinesterase (AChE) inhibitors and memantine, while non-medical options to influence early symptoms or the course of the disease are limited to lifestyle modifications which address modifiable risk factors (WHO 2012; WHO 2019). Recent data indicate a falling incidence of dementia which supports the theory that modifying individual risk may be possible (Larson 2013). One option to alter risk is dietary modification, an option that has increasingly gained importance in research into the primary and secondary prevention of dementia (Prince 2014).

### Description of the intervention

The dietary supplement, Souvenaid, is marketed as a medical food product for individuals in the early stages of Alzheimer's disease. It is intended to be consumed under medical supervision, in addition to the usual diet. The recommended dose is one bottle (125 ml) daily. The preparation is available in several flavours and contains natural food ingredients in a special patented composition (Fortasyn Connect™) (Nutricia 2014).

According to the manufacturer, the composition is designed to promote synaptic formation, which in turn is assumed to be strongly correlated with cognitive function. The drink contains a combination of docosahexaenoic acid, eicosapentaenoic acid, uridine monophosphate, choline and folate, combined with vitamins, minerals and trace elements (see Table 1). The

manufacturer reports no safety concerns. Due to its ingredients, the preparation is not recommended for individuals with galactosaemia (Nutricia 2014).

### How the intervention might work

The manufacturer of Souvenaid claims that the formulation was primarily designed to support the formation and function of synapses in the brains of people with Alzheimer's disease.

Synapses undergo constant change and remodelling, a phenomenon described as synaptic plasticity. Synaptic loss and dysfunction, one of the hallmarks of Alzheimer's disease, is thought to be closely linked to cognitive decline (Alix 2011; Scheff 2007). Maintaining or remodelling synapses could maintain better functioning of brain networks, resulting in improved cognitive functions. This might be supported directly by the supply of nutrients important in brain cell metabolism. Phosphatide subunits are a major component of synaptic membranes. It has been proposed that their biosynthesis can be supported by the consumption of specific nutrients known to be precursors for membrane phosphatides (Cansev 2008).

Research findings indicate lower plasma levels of several nutrients in individuals with Alzheimer's disease compared with cognitively healthy elderly individuals (Doecke 2012; Lopes 2013). It has been hypothesised that individuals with Alzheimer's disease might have increased requirements for certain nutrients due to alterations in diet, metabolism, uptake or use of nutrients (Mi 2013). Supplementing the diet with these nutrients could improve nutritional status, which in turn could have a favourable effect on brain cell metabolism and hence on memory and cognition.

This theory gains some support from preclinical studies. The main components of Souvenaid (Fortasyn Connect™) are omega-3 long-chain poly-unsaturated fatty acids (omega 3 PUFAs), uridine monophosphate and choline. Several animal studies indicate that additional administration of these nutrients can increase levels of brain phosphatides, synaptic proteins, or the number of dendritic spines on hippocampal neurons (Cansev 2008). Souvenaid also contains several vitamins, minerals and trace elements which are claimed to enhance the bioactivity of the precursor components (Nutricia 2014).

### Why it is important to do this review

Souvenaid is claimed to improve the cognitive function of individuals with Alzheimer's disease and to have no significant side effects. Considering the enormous impact of dementia on quality of life, a safe and effective dietary intervention would be of great interest to people with Alzheimer's disease. We believe it is important to systematically review the evidence on the efficacy and safety of Souvenaid in order to help people with Alzheimer's disease make decisions about its use.

## OBJECTIVES

To assess the effects of Souvenaid on incidence of dementia, cognition, functional performance, and safety in people with Alzheimer's disease.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

We included randomised controlled trials (RCTs) and cluster-randomised trials, published or unpublished, reported in any language. Since Alzheimer's disease is a progressive disease, we planned to include only data from the first period of cross-over randomised trials.

#### Types of participants

We included individuals with mild cognitive impairment (MCI) due to AD, or prodromal AD, or any severity of dementia due to AD.

A diagnosis of MCI should have been made in accordance with published clinical core criteria for MCI due to Alzheimer's disease (Albert 2011) as follows.

- Concern about a change in cognition.
- Impairment in one or more cognitive domains.
- Preservation of independence in functional abilities.
- Not demented (no significant impairment in social or occupational functioning).

We also accepted earlier published criteria for MCI (e.g. Petersen 1999). We included diagnostic criteria incorporating biomarkers if they had been assessed in addition to common MCI criteria, e.g. in the IWG criteria for prodromal AD (Dubois 2007).

Diagnosis of Alzheimer's disease dementia should have been made in accordance with internationally-accepted guidelines such as *Diagnostic and Statistical Manual of Mental Disorders* (DSM), *International Classification of Diseases* (ICD) or the National Institute of Neurological and Communicative Disorders and Stroke and the Alzheimer's Disease and Related Disorders Association (NINCDS-ADRDA) criteria (DSM III-R; DSM IV; McKhann 2011; WHO 1992).

Since Alzheimer's disease is the most common cause of dementia (WHO 2012; WHO 2019), we planned in our protocol for this review (Burckhardt 2015) to include RCTs even when MCI or dementia subtype at baseline had not been specified, as long as data from people with dementia in general could be examined separately. We excluded studies specifically investigating other dementia types, or MCI due to other causes (e.g. vascular disease). If data from individuals with dementia or MCI were not presented separately from those of others (e.g. healthy volunteers) we aimed to obtain these data from the trial authors.

We included participants at any stage of dementia who were able to ingest Souvenaid (Fortasyn Connect™) orally or by tube feeding. There were no restrictions based on setting, gender, ethnicity or other characteristics.

#### Types of interventions

The intervention of interest was Souvenaid (Fortasyn Connect™). We considered any dosage and frequency of administration. The European Medicines Agency (EMA) suggested at the time of the protocol a follow-up of at least six months, to demonstrate short-term effects on outcomes related to cognition (EMA 2008). Meanwhile, a minimum trial duration of 18 months has been

assumed to be sufficient for disease-modifying treatments (EMA 2018). However, Souvenaid is not currently subject to the same regulatory requirements as drugs. We therefore did not expect to find many long-term studies. Following the approach of the German Institute of Quality and Efficiency in Health Care (IQWiG 2008), we decided to compromise and accept studies with a treatment duration of at least 16 weeks.

We investigated the following treatment comparison.

- Souvenaid (Fortasyn Connect™) compared with a placebo.

We considered a placebo as appropriate if it was not expected or known to influence cognitive performance.

## Types of outcome measures

### Primary outcomes

We assessed the effect of Souvenaid on the following.

- Incidence of Alzheimer's disease dementia in individuals with MCI/prodromal AD at baseline
- Changes in global cognitive function and specific cognitive functions (e.g. memory) measured by validated tools such as:
  - \* Alzheimer's Disease Assessment Scale-Cognitive subscale (ADAS-cog) (Rosen 1984);
  - \* Mini-Mental State Exam (MMSE) (Folstein 1975);
  - \* Rey Auditory Verbal Learning Test (RAVLT) (Schmidt 1996);
  - \* Wechsler Memory Scale (Wechsler 2010);
  - \* Neuropsychological Test Battery (NTB) (Harrison 2007).
- Changes in functional outcomes (e.g. activities of daily living) measured by validated tools such as:
  - \* Alzheimer's Disease Activities of Daily Living International Scale (ADCS-ADL) (Galasko 1997);
  - \* Gottries-Bråne-Steen-Skala, Activities of Daily Living (ADL) subscale (GBS-ADL) (Bråne 2001).
- Changes in combined cognitive-functional outcomes measured by validated tools such as:
  - \* Clinical dementia rating scale - Sum of Boxes (CDR-SOB) (O'Bryant 2008);
  - \* Alzheimer's Disease Co-operative Study-Clinical Global Impression of Change (CIBIC-Plus) (Schneider 1997).
- Adverse events and adverse effects

We use the term 'adverse events and adverse effects' in line with the terminology in the PRISMA harms checklist (Zorzela 2016) and the *Cochrane Handbook* (Peryer 2020), in which adverse event means "An unfavourable outcome that occurs during or after the use of a drug or other intervention but is not necessarily caused by it" and adverse effect means "An unfavourable outcome that occurs during or after the use of a drug or other intervention and the causal relation between the intervention and the event is at least a reasonable possibility" (Zorzela 2016; Peryer 2020). To report the adverse events, we have used an exploratory approach in order to capture all mentioned adverse events without prespecification (Peryer 2020).

### Secondary outcomes

The secondary outcomes are:

- concordance with intervention;

- quality of life;
- non-cognitive symptoms associated with dementia (e.g. changes in mood, alterations in circadian rhythm);
- entry to institutional care;
- hospital admissions; and
- mortality.

We concentrated on outcomes relevant for patients and included no biomarker outcomes.

## Search methods for identification of studies

### Electronic searches

We searched ALOIS ([www.medicine.ox.ac.uk/alois](http://www.medicine.ox.ac.uk/alois)), the Cochrane Dementia and Cognitive Improvement Group's Specialised Register, using the search terms: Souvenaid OR Fortasyn. The most recent search was performed on 24 June 2020.

ALOIS is maintained by the Information Specialist of the Cochrane Dementia and Cognitive Improvement Group and contains dementia and cognitive improvement studies identified from the following.

- Monthly searches of a number of major healthcare databases: MEDLINE, Embase, CINAHL, PsycINFO and Lilacs.
- Monthly searches of a number of trial registers: metaRegister of Controlled Trials; Umin Japan Trial Register; WHO portal (which covers [ClinicalTrials.gov](http://ClinicalTrials.gov); ISRCTN; Chinese Clinical trials Register; German Clinical trials register; Iranian Registry of Clinical trials and the Netherlands National Trials Register, plus others).
- Quarterly search of the Cochrane Library's Central Register of Controlled trials (CENTRAL).
- Six-monthly searches of a number of grey literature sources: ISI Web of knowledge Conference Proceedings; Index to Theses; Australasian Digital Theses.

To view a list of all sources searched for ALOIS see [About ALOIS](#) on the ALOIS website.

We ran additional separate searches in many of the above sources to ensure that we retrieved the most up-to-date results. The sources searched and the search strategies used can be seen in [Appendix 1](#).

### Searching other resources

We contacted the study authors of the included trials and the sponsor Nutricia for overlooked, unpublished and ongoing trials. We also reviewed reference lists from all included studies and relevant reviews. We screened the reference lists of landmark papers, reviews, and included studies for additional studies, and assessed their suitability for inclusion in the review.

## Data collection and analysis

### Selection of studies

We managed all references retrieved by the searches using EndNote (X9) (Endnote 2011). We removed duplications of the same references.

Two review authors (MB, AF) independently examined titles and abstracts to identify eligible studies. If the relevance of a study

was not clear, we made the decision based on the full text. We resolved differing opinions on the eligibility of studies by discussion, and if necessary by involving a third review author. For all full texts of studies eligible for inclusion, we acquired all errata and supplementary data as well. It was not necessary to employ translation services. We linked multiple reports and conference abstracts of the same study together.

Two review authors (MB, AF) evaluated full texts of relevant articles independently according to the eligibility criteria. They were not blinded to study data.

We resolved disagreements by discussion, and, if necessary, by involving a third review author. We listed final decisions for the exclusion of studies and of articles which were retrieved in full text (see [Characteristics of excluded studies](#)). The selection process is documented according to the PRISMA statement ([Liberati 2009](#)) in Figure 1.

### Data extraction and management

Two review authors (MB, AF) independently read and extracted the data from each included study. If any discrepancies occurred, we involved a third review author to resolve the matter. Depending on the topic, the third review author was a methodologist or a content area expert. In case of language ambiguity, we planned to involve methodologists or healthcare professionals familiar with the language in question, but this was not necessary.

We used an electronic data extraction form, including source, eligibility, methods, participants, interventions, comparators, outcomes, results and miscellaneous notes, according to the *Cochrane Handbook for Systematic Reviews of Interventions* ([Page 2020](#)). We also assessed details of funding source, declarations of interest of the primary investigators, and methods used to control possible conflicts of interests. The form was pre-tested and used in a comparable review from our review group ([Burckhardt 2016](#)).

We extracted the latest available data reported by the study.

For continuous data, we extracted the mean or, if this was not available, the mean change from baseline, standard deviation (SD) and the number of participants used to measure the outcome for each group.

For dichotomous outcomes we extracted the number of participants in each outcome group. If the data provided were insufficient, we attempted to obtain the missing information from the authors and the sponsors of the trials (see the section [Dealing with missing data](#)).

If a paper reported only an estimate of an effect size (e.g. mean difference between groups for continuous data, or odds ratio or risk ratio for dichotomous data, along with corresponding standard errors or equivalent measures of uncertainty), then we extracted these data instead.

Whenever possible, we extracted intention-to-treat data, i.e. analysing all participants according to the group randomisation. We also extracted information on the amount of missing participant data, the statistical approach used to deal with missing data, and the level of significance as reported. Whenever possible, we also extracted and reported data from available-case analyses or data from 'per protocol' analyses. We contacted the main author or the

sponsor if we were unable to obtain the necessary data from the trial report.

For adverse events and adverse effects, we recorded under general safety the number of participants who had at least one (serious) adverse event. We also sought data on the number of adverse events and on frequent combinations of adverse events.

One review author (MB) entered the data into Review Manager 5 ([RevMan 2019](#)). Another author (from AF and AW) checked the data for accuracy.

We also extracted information on study name, methods, participants, interventions, outcomes, starting date, contact information and other notes on ongoing but apparently eligible trials and trials which we were unable to classify for any reason.

### Assessment of risk of bias in included studies

Two review authors (MB, AF) independently assessed the risks of bias for each study, using the Cochrane 'Risk of bias' tool ([Higgins 2011a](#)). We resolved any disagreements by discussion, involving the other review authors if necessary. We describe the risks of bias of all included studies in the [Characteristics of included studies](#) tables and in narrative form in the main text. We also provide an overall judgement of the included studies with a 'Risk of bias' summary (see Figure 1).

In our protocol we explicitly considered potential methods used to prevent undue industry influence during the clinical trial process. We therefore assessed additional criteria which are presented in detail in [Table 2](#). We intended to use this information to consider whether specific aspects of methodology might have influenced the results of meta-analyses (i.e. to explore sources of heterogeneity, as advised in the *Cochrane Handbook* ([Higgins 2011a](#))).

### Measures of treatment effect

We planned to use mean differences or standardised mean differences with 95% confidence intervals for continuous outcomes, and risk ratio with 95% confidence intervals for dichotomous outcomes.

Commonly-used scales in dementia trials are often coded ordinaly. We treated data measured with scales comprising more than 10 categories as continuous variables, assuming a normal distribution.

### Unit of analysis issues

The unit of analysis was the person with dementia.

### Dealing with missing data

For all included studies, we sought additional data or clarifications from corresponding authors or the study sponsor.

We considered both published and unpublished data obtained from the study authors. We took the amount and distribution of missing data into account when we considered the risk of bias due to missing data.

We intended to report intention-to-treat analyses and, if this was not possible, per protocol analyses along with sensitivity analyses

to assess the robustness of their results to imputations assuming poor outcomes.

None of the included trials were able to assess outcomes from all randomised participants. All trials used logistic regression models to predict data from missing participants over time. These models are based on the assumption that data are missing at random. The impact of missing data under the 'missing not at random' assumption was investigated in one trial ([LipiDiDiet study 2017](#)).

We intended to report the results of per protocol analyses alongside the results from the advanced models reported, but these were only published for the [LipiDiDiet study 2017](#). For the other trials, we were unable to obtain these analyses from the sponsor Nutricia.

The following terms and definitions were used within the trials. We use them for the presentation of the results unless otherwise stated.

- intention-to-treat-population (ITT). This includes all participants randomised ([Souvenir II study 2012](#); [S-Connect study 2013](#))
- All-subjects-treated population (AST). This includes all randomised participants who received at least one dose of the study product ([Souvenir II study 2012](#); [S-Connect study 2013](#)). All three trials used this population for the safety analysis.
- Modified intention-to-treat population (mITT). This included all randomised participants "excluding visit data after the start of rescue medication" ([LipiDiDiet study 2017](#)).
- Per protocol population."The per-protocol population consists of all participants from the modified intention-to-treat population, excluding participants or distinct visits of participants with major protocol deviations" ([LipiDiDiet study 2017](#)). Participants were excluded from PP if they did not comply with major eligibility criteria, did not consume at least one study product or lived in the same household with another study participant randomised to the other intervention arm ([LipiDiDiet study 2017](#)).

Two trials ([Souvenir II study 2012](#); [S-Connect study 2013](#)) presented descriptive statistics which were stated to be for the ITT population. However, the numbers of the participants on which the means and SDs are based differ from the numbers of participants randomised. We regarded the populations described by these statistics as 'available cases' and use the term 'available-case analysis' for our analyses accordingly. This term is often used for analyses "in which data are analysed for every participant for whom the outcome was obtained" [Higgins 2011b](#). We use this term also for analyses based on "observed mean changes from baseline", which was presented for the mITT population in the [LipiDiDiet study 2017](#).

### Assessment of heterogeneity

To assess clinical heterogeneity, we examined the data extraction tables and considered between-study variability with respect to participants, interventions, and outcome measurements.

We had intended to evaluate statistical heterogeneity by using Chi<sup>2</sup> and I<sup>2</sup> statistics.

### Assessment of reporting biases

We tried to minimise reporting bias by including both published and unpublished trials. We compared conference abstracts and trial registry entries with published data.

We did not identify enough trials to justify the use of a funnel plot or Egger's test for asymmetry ([Egger 1997](#)) to explore reporting biases or other small-study effects.

### Data synthesis

We intended to perform meta-analyses for all primary and secondary outcomes using Review Manager 5 ([RevMan 2019](#)) where there were sufficient data from included studies to estimate an overall treatment effect. As specified in our protocol ([Burckhardt 2015](#)), we intended to use comparable time points ( $\pm 1$  week) for all meta-analyses and to investigate the impact of baseline cognition in subgroups.

We examined participants, interventions, and outcomes in the included trials in order to decide whether we could reasonably pool them. The included trials differed in participants, outcome scales, follow-up times and analysis methods. However, we considered that the [LipiDiDiet study 2017](#) and the [Souvenir II study 2012](#) were sufficiently similar for meta-analyses to be informative. To perform meta-analyses, more data would have been needed (means, measures of variance). Since we were unable to obtain the necessary data from the responsible project co-ordinator of the [LipiDiDiet study 2017](#) or from the sponsor Nutricia (responsible for the data of the [Souvenir II study 2012](#) and [S-Connect study 2013](#)), we provide a narrative account of all results as reported by the authors of the studies.

### Subgroup analysis and investigation of heterogeneity

To explore possible sources of heterogeneity, we had prespecified the following subgroup analyses:

- Baseline Mini-Mental State Exam (MMSE) score  $\geq 24$  versus  $< 24$ ;
- Baseline nutritional status (e.g. higher versus lower plasma triglycerides or higher versus lower Subjective Global Assessment scores).

Given the available data, it was not possible to investigate these subgroups.

### Sensitivity analysis

We had prespecified sensitivity analyses to investigate the impact of missing data but were unable to do this because the data were unsuitable for meta-analysis.

### Summary of findings and assessment of the certainty of the evidence

We used the GRADE approach ([Guyatt 2011](#)) to interpret the findings and present them in 'Summary of findings' tables, as recommended by Cochrane ([Schünemann 2020](#)). We considered all primary outcomes to be important, and present them in the 'Summary of findings' tables. With this approach, we deviated from our plan to rate all outcomes with a consumer group (see also [Differences between protocol and review](#)).

GRADE distinguishes quality in four possible ratings: high, moderate, low and very low. The quality-of-evidence ratings in

GRADE describe the degree of confidence which we can place in the estimates of treatment benefits and harms (see explanations below the 'Summary of findings' tables). Results of RCTs without any limitations are generally rated as high quality. Several factors (imprecision of effect estimates, risk of bias in included studies, inconsistency of results, indirectness of evidence and publication bias) can lead to the downgrading of the evidence (Guyatt 2011). These factors are described below the 'Summary of findings' tables.

## RESULTS

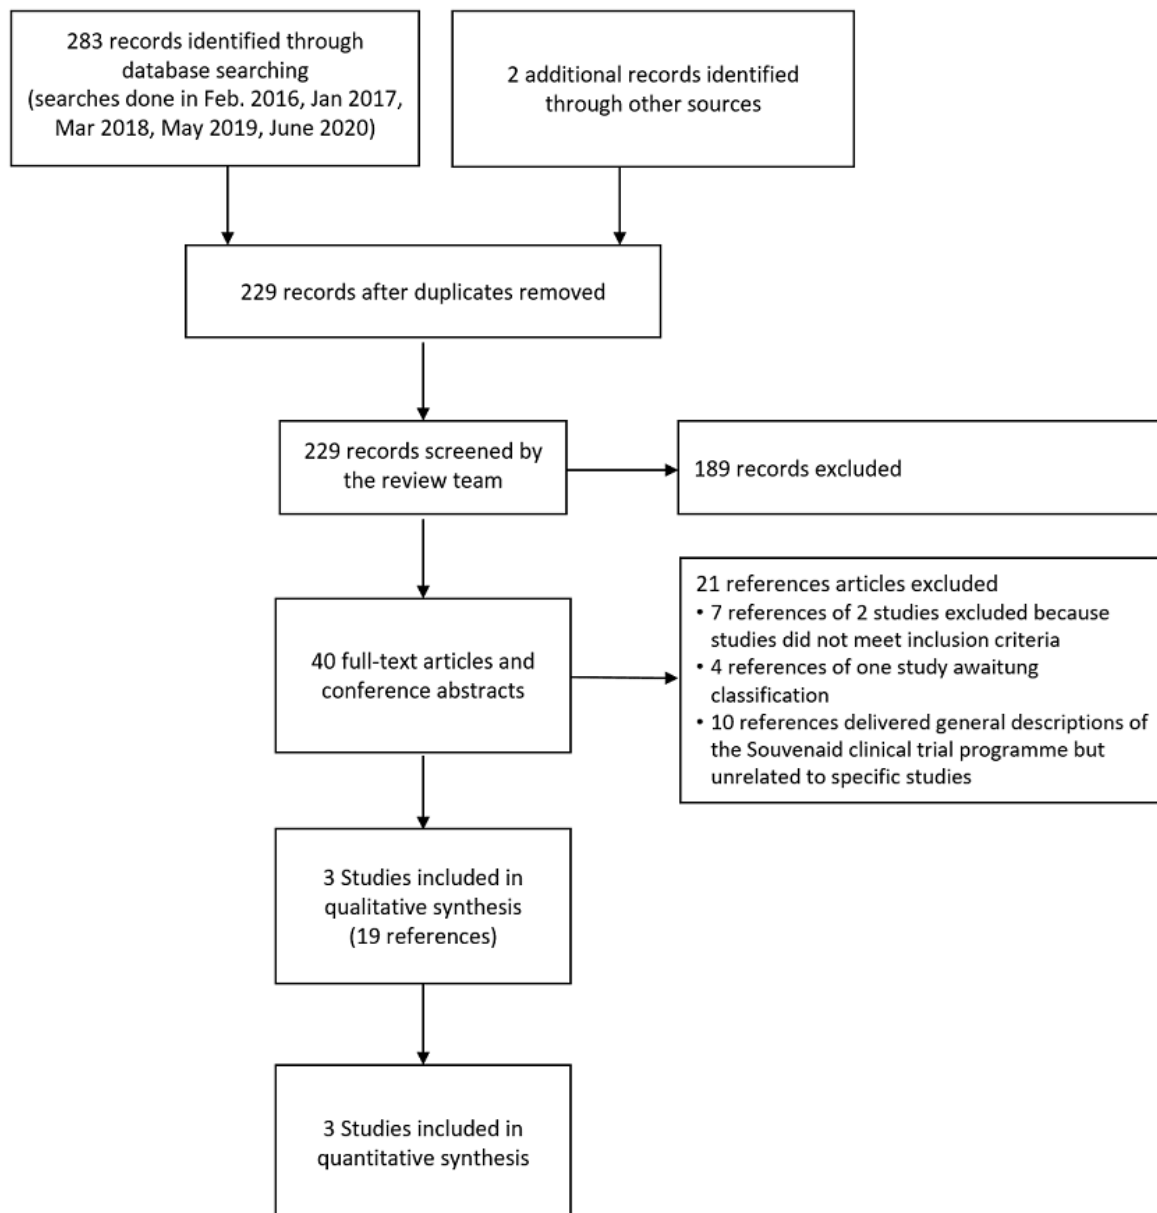

### Description of studies

#### Results of the search

The electronic searches from the five searches run for this review (February 2016, January 2017, March 2018, May 2019 and June 2020) by Anna Noel-Storr and Candida Fenton, Information Specialists for the Cochrane Dementia and Cognitive Improvement Group, retrieved a total of 283 references, which were supplemented by two further references (285 references in

total). After deduplication, 229 references were left. We identified no further reference by scanning the reference lists of landmark papers and included studies. We received no information about further published or unpublished studies from experts or from Nutricia. Two review authors (MB, AF) independently assessed the 229 references and discarded 189 which were not relevant. Two review authors (MB, AF) independently assessed the remaining 40 articles and related conference abstracts for eligibility. Two trials did not meet our inclusion criteria (see [Characteristics of excluded studies](#)). We included 19 articles covering to three trials ([LipiDiDiet study 2017](#); [S-Connect study 2013](#); [Souvenir II study 2012](#)). One trial registered in the Netherlands Trial Register ([NL-ENIGMA](#)) matched our selection criteria for its secondary outcomes. In spring 2019 we contacted the manufacturer and the contact person named in the trial registry. So far, the secondary endpoints relevant for this review have not been published. The selection process is presented in accord with the PRISMA statement ([Liberati 2009](#)) (see [Figure 1](#)). Because of the small number of studies, we were unable to use the funnel-plot method to look for any indication of unpublished studies.

**Figure 1. Study flow diagram**

**Included studies**

All three included studies were published, randomised, double-blind, placebo-controlled trials with a parallel-group design ([LipiDiDiet study 2017](#); [S-Connect study 2013](#); [Souvenir II study 2012](#)). Participants in all trials received once daily either 125 ml Souvenaid or an iso-caloric control drink which was identical in taste, consistency and appearance but lacked Fortasyn Connect™. Two trials ([S-Connect study 2013](#); [Souvenir II study 2012](#)) included participants with diagnosed dementia due to Alzheimer's disease, whereas one ([LipiDiDiet study 2017](#)) included participants with prodromal Alzheimer's disease. Two studies ([S-Connect study 2013](#); [Souvenir II study 2012](#)) received funding from the manufacturer of Souvenaid, Nutricia Advanced Medical Nutrition; the third study ([LipiDiDiet study 2017](#)) appeared to have no industry funding, although Nutricia Advanced Medical Nutrition is named as a

collaborator with the clinical study group. There are some further differences between the studies, which mainly concern the stage of Alzheimer's disease, outcome measurements and study duration, and which are described below. [Table 3](#) provides an overview of the main characteristics.

The largest trial ([S-Connect study 2013](#)) was conducted in the USA. It investigated Souvenaid in 527 participants with mild-to-moderate dementia due to AD over a treatment duration of 24 weeks. All participants received US Food and Drug Administration (FDA)-approved AD medication at a stable dose for at least four months prior to baseline (an inclusion criterion) and during the study period. Participants were recruited from the community or from specialised dementia clinics but were not institutionalised in nursing homes. Further inclusion criteria were: age 50 years or

more, diagnosis of probable AD (NINCDS-ADRA) with MMSE score between 14 and 24, and availability of a responsible study partner. People were excluded if they had neurological or psychiatric diseases other than AD significantly contributing to cognitive difficulties, drug abuse, depression score above 4 (on a 15-item scale), recent use of defined nutritional supplements (e.g. omega-3 PUFAs or high-energy drinks) or medication (e.g. anticholinergic), or were living in a nursing home. The study population had a mean MMSE score of 19.45 (SD 2.0) at the beginning of the trial and had a mean age of 76.75 years (SD 8.19).

The [Souvenir II study 2012](#) also investigated Souvenaid over a treatment duration of 24 weeks. The primary focus of the trial was on memory performance. It included 259 participants with mild dementia due to Alzheimer's disease, who were receiving no FDA-approved medication for AD. The trial was conducted in Europe and the participants were recruited in specialised AD centres in Spain, Italy, Germany, The Netherlands, Belgium and France. Important entry criteria were diagnosis of probable AD according to the NINCDS-ADRA criteria, no other cause of dementia shown by medical imaging, MMSE score of 20 or more, and a responsible caregiver. Among other reasons, participants were excluded if they had received approved medication for AD within three months prior to baseline, lived in a nursing home, had a depression score above 6 (on a 15-item scale) or consumed relevant nutritional supplements (e.g. omega-3 PUFAs) or medication. The groups did not differ by demographic characteristics at baseline. The study population had very mild dementia, with a mean MMSE score of 24.94 (SD 2.85) and a mean age of 73.80 (SD 7.69).

The [LipiDiDiet study 2017](#) lasted 24 months and was a multicentre trial conducted in Finland, Germany, the Netherlands and Sweden. The 11 study sites investigated Souvenaid in 311 participants with prodromal Alzheimer's disease, defined as a disorder of episodic memory and evidence of AD disease pathology (according to [Dubois 2007](#)). Major exclusion criteria were medication for AD, depressive disorders (DSM-IV) and regular high intakes of B, C or E vitamins and fish oils. Progression to Alzheimer's dementia was used as a secondary endpoint. The study population had a mean MMSE score of 26.65 (SD 2.01) at the beginning of the trial and had a mean age of 71.00 years (SD 6.60).

We contacted the sponsor Nutricia, responsible for the data of two of the studies ([S-Connect study 2013](#); [Souvenir II study 2012](#)), and the project co-ordinator of the [LipiDiDiet study 2017](#). We asked for six-month data to perform meta-analyses, for statistical clarifications, and for information on other aspects of the studies. We report the outcomes of these requests in the relevant sections and tables.

### Outcomes

A variety of outcome measures were used in the trials. [Table 3](#) summarises their use in the included studies. To aid interpretation, we present related estimates of clinically important changes as identified in the literature. Appropriate methods for defining valid estimates of minimum clinically important differences (MCIDs) are not yet fully developed and for scales covering multiple constructs (e.g. global severity, or combined cognitive-functional scales) are almost impossible to determine ([Molnar 2009](#)). Furthermore, what is estimated to be a clinically important difference depends on the population (e.g. severity of dementia) and contextual characteristics (e.g. balance between side effects and efficacy) and

might vary from different points of view (e.g. researcher or patient) ([Revicki 2008](#)). It would therefore have been ideal if participants taking Souvenaid had estimated their own features of a MCID from their point of view. However, none of the trials used this approach. The estimates we present of clinically important changes have been developed with varying methods and address different circumstances and disease severities. They should therefore be considered with caution.

### Incidence of Alzheimer's dementia in individuals with MCI at baseline

Incidence of Alzheimer's dementia was measured in [LipiDiDiet study 2017](#) according to [DSM IV](#) diagnostic criteria ([McKhann 2011](#)).

### Global and specific cognitive function measures

- The Neuropsychological Test Battery (NTB) ([Harrison 2007](#)) is a combination of validated cognitive tests measuring memory, praxis, language, working memory, attention, and psychomotor speed. Higher scores indicate better cognitive function. The memory domain of the test comprises the Wechsler Memory Scale Verbal Paired Associates test (immediate and delayed) and the Rey Auditory Verbal Learning Test (immediate and delayed). The executive domain includes Wechsler Memory Digit Span, Controlled Oral Word Association Test, Category Fluency, Trail-Making Test parts A and B. The data can be analysed at the level of the individual tests or can be standardised into z-scores, which in turn can be averaged to obtain z-scores for memory or executive sub-domains. It is also possible to get a composite (global) score of all test results. The NTB was developed for measuring cognitive change in Alzheimer's disease clinical trials in participants with relatively high Mini-Mental State Examination (MMSE) scores. Since its development the test battery has been modified in several trials ([Harrison 2011](#)). Contemporary versions of the NTB now commonly include measures of working memory, attention, and psychomotor speed in addition to the more traditionally-measured functions such as memory, praxis, and language. The two included trials ([LipiDiDiet study 2017](#); [Souvenir II study 2012](#)) which used the NTB both refer to the same publication ([Harrison 2007](#)), although the NTB subdomains and the NTB total composite scores used in the two trials were composed differently. The components of the respective Neuropsychological Test Battery and the composition of the individual subscores used in these studies are shown in [Table 4](#). We found no estimates in the literature of a meaningful change. Z-scores can be interpreted in accordance with Cohen ([Cohen 1988](#)), where an effect of 0.2 corresponds to a small effect, 0.5 to a moderate effect and 0.8 to a large effect.
- Another composite cognitive test battery was used in one study ([S-Connect study 2013](#)) to measure attention, concentration, executive function, processing speed and semantic memory. The test comprised the Digit Span from the Wechsler Memory Scale – Third Edition, the Concept Shifting Test, the Letter Digit Substitution Test, and Category Fluency ([Table 4](#)). The z-scores of the four tests were averaged to a 'global cognitive function composite score' as described in the article [S-Connect study 2013](#). The subscales are comparable to those used to measure executive function from the NTB used in the [LipiDiDiet study 2017](#). We considered this test battery to be a measure of executive function.

- The Alzheimer's Disease Assessment Scale - cognitive subscale (ADAS-Cog) comprises spoken language ability, comprehension of spoken language, recall of test instructions, word finding, following commands, naming objects, construction drawing, ideational praxis, orientation, word recall and word recognition. The score ranges from 0 to 70 points, with a higher score indicating greater impairment (Rosen 1984). The MCID is mainly estimated as 2 to 4 points (Huntley 2015; Molnar 2009; Schrag 2012; Vellas 2008).

#### Functional outcome measures (e.g. activities of daily living)

- The Alzheimer's Disease Cooperative Study-Activities of Daily Living (ADCS-ADL) (Galasko 1997) was specifically designed as part of a comprehensive test battery to assess activities of daily living in people with Alzheimer's disease in clinical trials. It consists of 23 criteria comprising simple everyday skills and complex activities, which are rated based on an interview with an informant who knows the affected study participant well. The range is from 0 to 78, with a higher score indicating better performance. Data on the MCID for ADCS-ADL is limited. One study group defined a threshold of a two-point score change as meaningful in an RCT investigating vitamin E and memantine in mild-to-moderate AD (Dysken 2014).
- The Disability Assessment for Dementia (DAD) (Gelines 1999) is used to evaluate the performance of daily activities in community-dwelling individuals with dementia, based on caregiver information. The instrument evaluates initiation, planning and execution of simple and complex activities. A final score is derived from the percentage of all questions rated positively, indicating that the study participant is able to perform the respective task without help. Higher scores therefore indicate better performance. We found no estimates of a meaningful change.

#### Combined cognitive-functional outcome measure

- The Clinical Dementia Rating scale-Sum of Boxes (CDR-SOB) (O'Bryant 2008) is a semi-structured interview of patients and informants for the assessment of cognition (memory, orientation, judgement/problem-solving) and function (community affairs, home/hobbies, personal care). The CDR-SOB total score ranges from 0 to 18 with scores from 3 to 15.5 indicating mild-to-moderate dementia (O'Bryant 2008). Lower scores indicate a better performance. The MCID was

recently estimated to be one scale point in MCI due to AD and two points in dementia due to AD (Andrews 2019).

#### Adverse effects

- All three included studies addressed the safety of the product. The S-Connect study 2013 explicitly classified safety as a secondary outcome. The others reported safety parameters. Safety assessments included at a minimum: recordings of adverse events, the monitoring of vital signs, and additional laboratory parameters.

Some secondary outcomes defined in the protocol of this review (Burckhardt 2015) (concordance with intervention, entry to institutional care, hospital admissions and mortality) were not assessed explicitly as outcomes in any of the included trials. We considered any information reported by the trial authors which was relevant to institutionalisation, hospital admission or mortality in the adverse effects section (see [Effects of interventions](#)).

#### Excluded studies

We excluded 21 references and listed the reasons in Figure 1. Most of the references were excluded because they delivered general descriptions of the Souvenaid clinical trial programme but unrelated to a specific study. We excluded the [Souvenir I study 2010](#) because the treatment with Souvenaid lasted only 12 weeks. The [Souvenir II study 2012](#) had an open-label extension with a separate registration number (NTR 2456; [Souvenir II OLE study 2015](#)), which we excluded because all participants received the active product.

One further study focused on cerebral glucose metabolism and had corresponding biomarkers as endpoints (NL-ENIGMA). However, among the secondary outcomes, endpoints are identified that may be relevant for this review. So far, no results for these outcomes have been published. For this reason, the study will remain in the [Ongoing studies](#) category, until it can finally be moved to the included or excluded studies.

#### Risk of bias in included studies

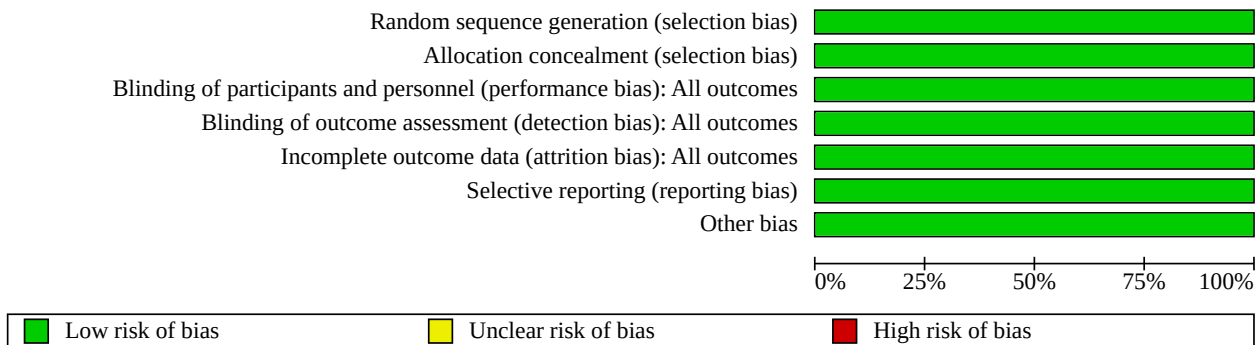

Overall, we judged the trials to be well-designed and well-conducted, and hence to be at low risk of bias. Our 'Risk of bias' judgments are described in the [Characteristics of included studies](#) tables and also depicted in the 'Risk of bias' summary and 'Risk of bias' graph (see [Figure 2](#); [Figure 3](#))

**Figure 2. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.**

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias): All outcomes	Blinding of outcome assessment (detection bias): All outcomes	Incomplete outcome data (attrition bias): All outcomes	Selective reporting (reporting bias)	Other bias
LipiDiDiet study 2017	+	+	+	+	+	+	+
S-Connect study 2013	+	+	+	+	+	+	+
Souvenir II study 2012	+	+	+	+	+	+	+

**Figure 3.**

**Allocation**

All trial reports (Souvenir II study 2012; S-Connect study 2013; LipiDiDiet study 2017) included details of adequate sequence generation and allocation concealment methods.

**Blinding**

All trials (Souvenir II study 2012; S-Connect study 2013; LipiDiDiet study 2017) used adequate blinding methods for participants and staff by using placebo drinks with an identical taste and appearance. The randomisation code was not broken until the primary outcomes were analysed.

**Incomplete outcome data**

In all trials (S-Connect study 2013; Souvenir II study 2012; LipiDiDiet study 2017), the amount of missing outcome data was equally distributed between groups, but the reasons for study discontinuation were not described in sufficient detail in the published papers. However, the overall numbers of dropouts were low (< 22% in the longer-lasting LipiDiDiet study 2017 trial) and all trial authors provided detailed information on the reasons for dropouts in personal communications. We therefore judged the influence of missing data on the overall results as marginal. Overall, missing data were considered in intention-to-treat-analyses.

**Selective reporting**

All included trials (S-Connect study 2013; Souvenir II study 2012, LipiDiDiet study 2017) reported the primary outcomes as described in the protocols published in trial registries. In the LipiDiDiet study 2017, changes of outcome measures were explained and made prior to database lock. Relevant serious adverse events (SAEs) are presented with distribution to the groups.

**Other potential sources of bias**

We found no further potential sources of bias, and rated the risk as low for all three studies.

**Effects of interventions**

See: **Summary of findings 1** Souveniraid compared to placebo for MCI/prodromal AD; **Summary of findings 2** Souveniraid compared to placebo for mild Alzheimer's disease dementia; **Summary of findings 3** Souveniraid compared to placebo for mild-to-moderate Alzheimer's dementia

See **Summary of findings 1**; **Summary of findings 2**; **Summary of findings 3**.

**Incidence of Alzheimer's disease dementia in individuals with MCI/prodromal AD (primary review outcome)**

Incidence of Alzheimer's disease dementia was only investigated in the LipiDiDiet study 2017, which was the only study in which participants did not have a diagnosis of dementia at baseline. Souveniraid for 24 months probably results in little or no difference in incidence of dementia. Of all randomised participants, 41% (62 of 153) were diagnosed with dementia in the Souveniraid group and 37% (59 out of 158) in the control group. The ITT analysis based on all randomised participants showed no difference between the groups (RR 1.09, 95% CI 0.82 to 1.43; 1 trial, 311 participants; **Analysis 1.1**). We considered this as moderate-quality evidence, downgraded for imprecision.

**Changes in global and specific cognitive functions (primary review outcomes)**

**MCI/prodromal AD**

In the LipiDiDiet study 2017 a five-component NTB z-score (named "NTB primary endpoint z-score" in the study) was used as the primary outcome in participants with prodromal AD. **Table 4** shows the components of the individual subscores. At 24 months, the mean change from baseline in NTB primary endpoint z-score (five components) (a higher score was better) was -0.028 (SD 0.453) in the Souveniraid group and -0.108 (SD 0.528) in the placebo group. Souveniraid probably results in little to no difference between the groups (MD 0.08, 95% CI -0.04 to 0.20; 1 trial, 275 participants) in our analysis based on available cases (**Analysis 1.2**). The linear mixed model (LME) analysis performed by the study authors showed no statistically significant benefit of Souveniraid in a 24-month period, whether in a modified intention-to-treat analysis (LME: MD 0.10, 95% CI -0.04 to 0.24; P = 0.17; 311 participants) or in a per protocol analysis (LME: MD 0.14, 95% CI -0.02 to 0.30; P = 0.080; 295 participants). The results for the NTB total composite z-score (16 components, **Table 4**) were similar ((MD 0.01, 95% CI -0.08 to 0.10; 274 participants; **Analysis 1.3**). We considered all analyses as moderate-quality evidence, downgraded for imprecision.

At 24 months, the mean change from baseline in the NTB memory domain z-score (three components, **Table 4**) was -0.003 (SD 0.569) in the Souveniraid group and -0.13 (SD 0.619) in the placebo group (a higher score was better). Souveniraid probably results in little

to no difference between the groups (available cases) (MD 0.13, 95% CI -0.01 to 0.27; 1 trial, 274 participants; [Analysis 1.4](#)). This remained stable in the modified intention-to-treat analysis (LME: MD 0.14, 95% CI -0.03 to 0.30; P = 0.10; 311 participants) and per protocol analysis (LME: MD 0.18, 95% CI -0.005 to 0.37; P = 0.057; 295 participants) performed by the study authors ([LipiDiDiet study 2017](#)). We considered this as moderate-quality evidence, downgraded once for imprecision.

At 24 months, the mean change from baseline in the NTB executive function domain z-score (four components, [Table 4](#)) was -0.145 (SD 0.445) in the Souvenaid group and -0.039 (SD 0.506) in the placebo group (a higher score was better). Souvenaid probably results in little to no difference between the groups (MD -0.11, 95% CI -0.22 to 0.01; 1 trial, 274 participants; [Analysis 1.5](#)) (available cases). The models performed by the authors showed similar results in a modified ITT analysis (LME: MD z-score -0.04, 95% CI -0.18 to 0.10) or in a per protocol analysis (LME: 0.01, 95% CI -0.14 to 0.16). We considered this as moderate-quality evidence, downgraded once for imprecision.

### Mild AD dementia

Cognition was measured with the NTB in mild AD ([Souvenir II study 2012](#)). After 24 weeks, the mean change from baseline in the NTB total composite z-score (12 components, [Table 4](#)) was 0.12 (SD 0.278) in the Souvenaid group and 0.035 (SD 0.286) in the placebo group (a higher score was better). Souvenaid probably results in little to no meaningful difference, depending on the statistical approach. There was some difference between the groups in favour of Souvenaid in our available-case analysis (MD 0.08, 95% CI 0.00 to 0.17; 1 trial, 172 participants; [Analysis 2.1](#)), which was also observed when missing data were considered in the mixed model of repeated measure (MMRM) analysis performed by the study authors (P = 0.035; 259 participants), but not in the trajectories over 24 weeks (MMRM: P = 0.053; 259 participants). We considered this as moderate-quality evidence, downgraded once for imprecision.

Memory was assessed as the primary outcome in participants with mild AD ([Souvenir II study 2012](#)) by using the NTB memory function domain z-score (five components, [Table 4](#)) (a higher score was better). After 24 weeks, the mean change from baseline in the Souvenaid group was 0.202 (SD 0.395) and 0.111 (SD 0.463) in the placebo group. Souvenaid probably results in little to no meaningful difference, depending on the statistical approach. There was no difference between the groups after 24 weeks (MD 0.09, 95% CI -0.03 to 0.21; 1 trial, 206 participants) when we calculated the mean difference based on available cases ([Analysis 2.2](#)). The result is similar to the analysis performed by the authors where the change from baseline at week 24 was calculated in a MMRM based on the ITT population (MMRM: P = 0.090; 259 participants). The authors also considered missing data for the differences in the trajectories over time and in a sensitivity analysis with multiple imputations (MIs). The difference in the trajectories over 24 weeks showed a significant difference in favour of Souvenaid in the NTB memory function domain z-score (MMRM; P = 0.023; 259 participants). This result remained stable when the NTB total composite z-score (12 components, [Table 4](#)) was calculated by multiple imputations when one or two NTB items were missing (P = 0.032) ([Souvenir II study 2012](#)). We considered this as moderate-quality evidence, downgraded once for imprecision.

At 24 weeks the mean change from baseline in NTB executive function domain z-score (five components, [Table 4](#)) was 0.048 (SD 0.333) in the Souvenaid group and 0.006 (SD 0.323) in the placebo group (a higher score was better). Souvenaid probably results in little to no difference in executive function (specific cognitive function) on the NTB executive function domain z-score (MD 0.04, 95% CI -0.05 to 0.13; 1 trial, 192 participants; [Analysis 2.3](#)) (available-case analysis). The models based on the ITT population performed by the authors showed similar results for the change from baseline after 24 weeks (MMRM: P = 0.386; 259 participants) and in the trajectories over 24 weeks (MMRM: P = 0.69; 259 participants) ([Souvenir II study 2012](#)). We considered this as moderate-quality evidence, downgraded once for imprecision.

### Mild-to-moderate AD dementia

The [S-Connect study 2013](#) assessed cognitive function in people with mild-to-moderate AD dementia using the ADAS-cog as the primary outcome (lower score is better, score range 0 - 70). After 24 weeks, the mean score in the Souvenaid group was 25.44 (SD 11.56) and the mean score in the placebo group was 24.42 (SD 10.95). Souvenaid probably results in little to no difference in cognition. Our available-case analysis (MD 1.02, 95% CI -1.11 to 3.15; 1 trial, 428 participants; [Analysis 3.1](#)) and the ITT analysis performed by the authors (MMRM: MD 0.37; P = 0.51; 527 participants) showed no statistically significant difference between the groups. At 24 weeks, the mean global cognitive function composite z-score (four components, [Table 4](#)) was 0.09 (SD 0.74) in the Souvenaid group and 0.01 (SD 0.71) in the placebo group (a higher score was better). In the available-case analysis, there was no difference between the groups for cognition on global cognitive function composite z-score (four components, [Table 4](#)) (z-score) (MD 0.08, 95% CI -0.07 to 0.23; 1 trial, 364 participants). The ITT analysis also showed no difference (MMRM: P = 0.323; 527 participants). We considered both analyses as moderate-quality evidence, downgraded once for imprecision.

### Changes in functional outcome measures (e.g. activities of daily living) (primary review outcome)

#### MCI/prodromal AD

We found no evidence in this population.

#### Mild AD dementia

In the [Souvenir II study 2012](#) functional ability was measured on the DAD scale (no means presented) in participants with mild AD. The authors report no difference between the groups after 24 weeks (Mann-Whitney U test: P = 0.361; N of participants unclear). We downgraded the evidence once for imprecision.

#### Mild-to-moderate AD dementia

Souvenaid probably results in little to no difference in activities of daily living. Daily-living function was measured with the ADCS-ADL (a higher score was better, score range 0 - 78) in mild-to-moderate AD. After 24 weeks, the mean in the Souvenaid group was 54.66 (SD 15.56) and the mean in the placebo group was 54.15 (15.91). There was no evidence for a difference between the groups in our available-case analysis (MD 0.51, 95% CI -2.40 to 3.42; 1 trial, 451 participants) ([Analysis 3.3](#)) and in an ITT analysis performed by the study authors (MMRM: P = 0.77; 527 participants; [S-Connect study 2013](#)). We considered this as moderate-quality evidence, downgraded once for imprecision.

### Combined cognitive-functional outcome measure (primary outcome)

Combined cognition-function was measured with the CDR-SoB in two of the studies as a secondary outcome.

#### MCI/prodromal AD

The [LipiDiDiet study 2017](#) used the CDR-SoB (a higher score was worse, score range 0 - 18) as a secondary outcome. In this trial Souvenaid may slightly improve overall cognitive-functional performance. After 24 months, the mean change from baseline was 0.56 (SD 1.32) in the Souvenaid group and 1.12 (SD 1.72) in the placebo group. The difference was statistically significant in favour of Souvenaid. This effect was stable in our available-case analysis (MD -0.56, 95% CI -0.95 to -0.17; 1 trial, 230 participants; [Analysis 1.6](#)), in a modified ITT analysis (LME: MD -0.60, 95% CI -1.01 to -0.19; P = 0.005; 311 participants) and in a per protocol analysis (LME: -0.72, 95% CI -1.16 to -0.28; P = 0.002; 295 participants), both published by the study authors. We consider this as moderate-quality evidence, downgrade once for imprecision.

#### Mild AD dementia

We found no evidence for Souvenaid in this population.

#### Mild-to-moderate AD dementia

The [S-Connect study 2013](#) measured this combined outcome with the CDR-SoB (a higher score was worse, score range 0 - 18) after 24 weeks, and observed a mean of 6.89 (SD 3.35) in the Souvenaid group and 7.01 (SD 3.419) in the placebo group. Souvenaid probably results in little to no difference between the groups. There was no statistically significant difference between the groups in our available-case analysis (MD -0.12, 95% CI -0.74 to 0.50; 1 trial, 450 participant; [Analysis 3.4](#)) and when missing data were considered in an ITT analysis (MMRM: P = 0.50; 527 participants; [S-Connect study 2013](#)) performed by the study authors. We considered this as moderate-quality evidence, downgraded once for imprecision.

#### Adverse events and adverse effects (primary review outcome)

The European Medicines Agency (EMA) recommends an on-treatment follow-up of at least six months after short-term trials to demonstrate safety ([EMA 2018](#)). With a study duration of 24 weeks, the [S-Connect study 2013](#) and the [Souvenir II study 2012](#) did not fully meet this requirement. The [LipiDiDiet study 2017](#) had a treatment duration of 24 months.

All included studies describe the intervention as well-tolerated. Compliance with the study product seemed to be high ([LipiDiDiet study 2017](#): 93.4%; [S-Connect study 2013](#): 94.1%; [Souvenir II study 2012](#): 97.1%). The following results are all reported in an 'as treated' population.

For adverse events and adverse effects, we recorded under general safety the number of participants who had at least one (serious) adverse event. Some study participants had more than one adverse event. It was not possible to show which adverse events occurred together and whether there were frequent combinations.

All but one of the serious adverse events were considered to be unrelated to the use of the study product. The one serious adverse event (confusion) reported in the [S-Connect study 2013](#) that was considered to be possibly related to the use of the study product

was in the placebo group. In the terminology of the PRISMA harms checklist ([Zorzela 2016](#)) and the *Cochrane Handbook* ([Peryer 2020](#)), we consider this as a serious adverse effect.

None of the studies reported full causality assessment according to the PRISMA harms recommendations ([Zorzela 2016](#)).

#### MCI/prodromal AD

None of the serious adverse events in the [LipiDiDiet study 2017](#) were regarded as related to the study products. Some of the adverse events which contributed to study discontinuation seemed to be related to study product (adverse effects). This related to five participants in the active group (two with eczema, one each with abdominal pain upper, regurgitation, or lactose intolerance) and four participants in the control group (one each with diarrhoea, hypersensitivity, urticaria, or lactose intolerance and weight gain).

Adverse effects which did not lead to study discontinuation were not explicitly identified as such. The project co-ordinator informed us that if they had noticed adverse events which had been traceable to the intervention they would have reported them.

In the [LipiDiDiet study 2017](#) the safety analysis is also presented for all participants who received at least one dose of the study product. The proportion of participants affected by at least one adverse event during the 24 months was nearly equal in the Souvenaid group (132/152; 86.4%) and the placebo group (138/157; 87.9%) (RR 0.99, 95% CI 0.91 to 1.08; 309 participants). The frequency of at least one serious adverse event showed only small differences between the Souvenaid group (34/152; 22.4%) and the placebo group (30/157; 19.1%) (RR 1.17, 95% CI 0.76 to 1.81; 309 participants; [Analysis 1.7](#)). We downgraded the evidence once for imprecision.

The overall dropout rate was equally distributed between the Souvenaid group (21.7%) and control group (21.0%) (RR 1.03, 95% CI 0.67 to 1.58; 309 participants). The dropout rates due to adverse events (RR 1.55, 95% CI 0.57 to 4.25; 309 participants) and serious adverse events (RR 2.07, 95% CI 0.38 to 11.11; 309 participants) were also similar, but the very wide confidence intervals indicate the imprecision of the results ([Analysis 1.7](#)). The [LipiDiDiet study 2017](#) reported two hospital admissions within the study period of 24 months, but there were serious adverse events (e.g. cardiac operation) that would have led to additional hospital admissions beyond those reported. The [LipiDiDiet study 2017](#) had five deaths within 24 months, four in the Souvenaid group (one each due to infection and bronchial carcinoma, and two due to respiratory failure) and one in the placebo group (sudden death). The deaths were probably not due to the experimental or control interventions. The details of the adverse events of the [LipiDiDiet study 2017](#) are presented in [Table 5](#).

#### Mild AD dementia

In the [Souvenir II study 2012](#) 84.1% of the reported adverse events were assessed as being "not related" or "unlikely to be related" to the intervention (82.5% active group; 85.4% control group). Further details of the remaining 15.9% adverse events, which may be related to the interventions and therefore would be adverse effects, are not reported.

Regarding general safety, the [Souvenir II study 2012](#) showed the following results in the participants who received at least one unit of the study product (all participants, treated population): The

proportion of the participants affected by at least one adverse event during 24 weeks was lower in the Souvenaid group (67/129; 51.9%) than in the in the placebo group (78/129; 60.5%) (RR 0.86, 95% CI 0.69 to 1.07; 258 participants). Serious adverse events were higher in the Souvenaid group (10/129; 7.8%) than in the placebo group (6/129; 4.7%) (RR 1.67, 95% CI 0.62 to 4.45; 258 participants). The overall dropout rate was also a little higher in the Souvenaid group (RR 1.32, 95% CI 0.58 to 3.03; 259 participants). Few participants terminated the study due to adverse events or serious adverse events (2.3% in the intervention group and 1.65% in the placebo group) (RR 1.49, 95% CI 0.25 to 8.76; 259 participants; [Analysis 2.4](#)). Data on hospital admissions were not provided. There were no deaths during the 24 weeks of the study ([Souvenir II study 2012](#)).

None of the effects described in the [Souvenir II study 2012](#) reached statistical significance. We consider the evidence for adverse events as moderate, downgraded once for imprecision. We present detailed adverse events in [Table 6](#).

### Mild-to-moderate AD dementia

in the [S-Connect study 2013](#) there are no details on adverse events that might be related to the intervention (i.e. on adverse effects).

Regarding general safety, the [S-Connect study 2013](#) showed the following results in the participants who received at least one unit of the study product (all participants, treated population): The proportion of the participants affected by at least one adverse event during 24 weeks was lower in the Souvenaid group (150/264; 56.8%) than in the in the placebo group (165/260; 63.5%) (RR 0.90, 95% CI 0.78 to 1.03; 1 trial, 524 participants). Serious adverse events were fewer in the Souvenaid group (26/264; 9.8%) than in the placebo group (34/260; 13.1%) (RR 0.78, 95% CI 0.49 to 1.26; 524 participants). The overall dropout rate was similarly distributed in both groups (RR 0.94, 95% CI 0.62 to 1.42; 527 participants). Few participants terminated the study due to adverse events or serious adverse events. The relative effect in favour of the intervention group appears at first sight to be large, but it is based on small absolute numbers (2/265 in the intervention group and 4/262 in the placebo group) (RR 0.49, 95% CI 0.09 to 2.68; 527 participants; [Analysis 3.5](#)). Data on hospital admissions were not provided. One death due to malignant mesothelioma in the control group was reported in the [S-Connect study 2013](#).

None of the effects described in the [S-Connect study 2013](#) reached statistical significance. We consider the evidence for adverse events as moderate, downgraded once for imprecision. We present detailed adverse events in [Table 7](#).

In total, the number of body system-specific adverse events that occurred in the 24 months of the [LipiDiDiet study 2017](#) were mostly lower than the event rate in the two shorter studies with 24 weeks follow-up.

### Non-cognitive symptoms associated with dementia and quality of life (secondary review outcomes)

None of the studies assessed either non-cognitive symptoms associated with dementia or quality of life.

## DISCUSSION

### Summary of main results

We included three RCTs which investigated Souvenaid in 1097 participants at different stages of AD. The progression from MCI (prodromal AD) to dementia due to AD was measured in only one trial, which lasted over a period of 24 months. All of the studies measured cognitive function. The two RCTs which included participants with very mild or mild-to-moderate AD dementia also measured everyday function, whereas combined cognition-function was only measured in prodromal AD and mild-to-moderate AD dementia. All studies reported adverse events.

We found no convincing evidence of a benefit for Souvenaid on any of our primary or secondary outcomes, including moderate-quality evidence that Souvenaid does not affect incidence of dementia over two years in participants with prodromal AD at baseline.

The evidence for combined cognitive-functional outcomes is conflicting. The largest trial showed a small benefit in participants with prodromal AD. The difference proved stable under several statistical assumptions for missing participant data. However, taking recently-published MCID estimates for CDR-SoB in this population ([Andrews 2019](#)) into account, the difference is not clinically meaningful. There was little to no difference in participants with mild-to-moderate AD dementia.

Adverse effects observed were low in all trials. There were a number of adverse events, but to make a connection with Souvenaid or to reject it would put too much strain on the available data. We downgraded the evidence for imprecision because of wide confidence intervals.

Quality of life or other secondary review outcomes were not reported for any of the trials.

### Overall completeness and applicability of evidence

The trials investigated Souvenaid in an appropriate dose (according to the recommendation of the manufacturer). All trials included community-dwelling participants with prodromal AD, very mild and mild-to-moderate AD dementia who seem to accurately represent the population seen in clinical practice. According to the nutritional parameters reported, we further assumed that the participants were at low risk of nutritional deficiencies. Based on the available data, it was not possible to investigate Souvenaid in subgroups with nutritional deficiencies. We therefore cannot rule out that people with AD and poorer baseline nutritional status may benefit from Souvenaid. Nor can we draw any conclusions about its effects in people with advanced dementia.

All trials investigated relevant endpoints for people with AD, as recommended by an expert group of the European Medicines Agency ([EMA 2018](#)). They assessed cognition with different test batteries which may affect the comparability. It is assumed that these tests are sensitive enough to detect changes in people at the milder end of the disease spectrum, but so far there is no consensus about the validity of these tests for this purpose. However, all trials also assessed biomarkers, which we have not included since the utility of these is also still under debate ([EMA 2018](#)). Data permitting, we would have performed several meta-analyses at endpoints reported in the [LipiDiDiet study 2017](#) and the [Souvenir II study 2012](#). We also planned several sensitivity analyses

to test this approach. This plan followed the recommendation of the EMA and we think that from a clinical point of view, these populations are similar enough to be investigated together. Apart from the diagnoses, both studies included drug-naïve participants with similar MMSE scores. We specified in our protocol that we would pool data from comparable time points if outcomes were measured at more than one time point. However, we were not able to get six-month data which we could use for a meta-analysis. Both the sponsor Nutricia and the authors of [LipiDiDiet study 2017](#) declined to provide the data, with the argument that no meaningful scientific hypothesis exists for pooling intervention effects in these populations at this time point. Both lines of argument might be reasonable. There are scientific uncertainties in the field of AD about the optimal duration of follow-up for a trial and the demarcation of disease stages in this population ([EMA 2018](#)).

### Quality of the evidence

We assessed all three RCTs as being at low risk of bias in all domains according to the Cochrane 'Risk of bias' tool. By using the GRADE approach, we rated the overall quality of evidence for all outcomes as moderate. However, the evidence is based on single RCTs with some conflicting results.

### Potential biases in the review process

We prespecified inclusion of domain-specific cognitive outcomes without defining an explicit hierarchical order.

We excluded one RCT due to a short-term follow-up period of only 12 weeks. This study ([Souvenir I study 2010](#)) observed some beneficial effects. However, we do not see that the inclusion of this trial would have changed our overall conclusions. Two of the included studies were industry-funded. There were too few studies to use the funnel-plot method to look for indications of unpublished studies, so we cannot rule out this possibility.

We did not include biomarker measures, due to uncertain diagnostic validity in the field of dementia. We found no convincing evidence on patient-relevant dementia measures and decided not to compensate for this lack of evidence with biomarkers. We might change this approach in the future, if and when they are recommended as primary outcomes in dementia trials. We assessed beneficial and adverse effects in the same review and did not conduct a special search for studies assessing the unintended effects of the product. In so doing, we have taken the adverse events from our included studies, which are very low. Including data from non-randomised trials or other populations might have changed the numbers but probably not the certainty of the evidence.

### Agreements and disagreements with other studies or reviews

A systematic review by [Onakpoya 2017](#) investigated Souvenaid in Alzheimer's disease. Their search strategy, inclusion criteria and methods for meta-analysis differed slightly from ours. The authors included the trial with a follow-up of 12 weeks. They have further conducted meta-analyses by combining different measures. None

of the meta-analyses showed a difference between Souvenaid and the placebo. Altogether, the review's findings are in line with ours. To our knowledge, no systematic review included the recent [LipiDiDiet study 2017](#), which investigated the incidence of AD dementia as a secondary outcome.

## AUTHORS' CONCLUSIONS

### Implications for practice

Currently, there is no evidence that Souvenaid is useful for preventing progression from prodromal AD to dementia. Furthermore, we found no convincing evidence for the efficacy of Souvenaid in the treatment of symptoms of dementia due to Alzheimer's disease. These results were based on moderate-quality evidence. There are advantages for some outcomes, especially in early stages of the disease, but they are small and not consistent across all outcomes. Adverse effects and adverse events of Souvenaid seem to be uncommon. The evidence is drawn from three studies and data were insufficient for meta-analysis, so that our ability to draw conclusions about any effects is limited. The effects on more severe AD dementia remain unknown.

### Implications for research

One study reported some positive results for memory in very mild AD dementia, but we did not replicate this finding using a different statistical approach. Another reported significant beneficial effects in a combined measure of cognition and function (CDR-SoB) in participants with prodromal AD; this result was robust to different statistical models. These results should be replicated and investigated further, especially in participants at the very mild end of the AD continuum.

Souvenaid is a nutritional intervention. Future trials should investigate people with nutritional deficiencies or provide prespecified subgroup analyses for people at risk of malnutrition. From a review author's and a reader's perspective, it would be helpful if similar instruments were used to measure patient-relevant outcomes. With regard to further study design features, we refer to current recommendations on the clinical investigation of medicines in AD (i.e. [EMA 2018](#); [FDA 2018](#)), which we think can also guide trials investigating nutritional supplements.

## ACKNOWLEDGEMENTS

We acknowledge the work of the Cochrane Dementia and Cognitive Improvement Group (CDCIG) Information Specialists, Anna Noel-Storr who designed the search strategy and Candida Fenton who provided the search results. We also acknowledge Jenny McCleery (Co-ordinating Editor of the CDCIG) for her helpful editing and her valuable methodological comments. We also thank the peer reviewers Janice M. Ranson and Caryl Nowson for their thorough peer review, and consumer reviewer Catherine Hofstetter who gave us valuable feedback. Thanks also to Sue Marcus (Managing Editor of CDCIG) for her excellent support. We gratefully acknowledge Hanna Mass for her thorough proofreading and editing as a native speaker.

## CHARACTERISTICS OF STUDIES

### Characteristics of included studies [ordered by study ID]

**LipiDiDiet study 2017**
**Study characteristics**

Methods	<p>Randomised, placebo-controlled, multicentre trial</p> <p>Trial duration from April 2009 to June 2015</p>
Participants	<p>Countries: Finland, Germany, the Netherlands, and Sweden</p> <p>Diagnosis: prodromal Alzheimer's disease (mean MMSE 26)</p> <p>Follow-up: 24 months</p> <p>Inclusion criteria: age 55 – 85 years; fulfilled criteria for prodromal Alzheimer's disease as defined by a) disorder of episodic memory, and b) evidence for underlying Alzheimer's disease pathology (<a href="#">Dubois 2007</a>); MMSE score <math>\geq 24</math> or <math>\geq 20</math> if education level <math>\leq 6</math> years; use of non-prescription/prescription cognitive enhancers (e.g. ginkgo) and statins on a stable dose for at least 3 months prior to baseline; and availability of a responsible caregiver</p> <p>Exclusion criteria: participants with dementia according to <a href="#">DSM IV</a>; historical use of donepezil, rivastigmine, galantamine, or memantine, use of omega-3 preparations, alcohol or drug abuse, major depressive disorders (DSMIV) or other concomitant serious conditions, intake of vitamins B6, B12, folic acid, vitamin C, or vitamin E of more than 200% of the recommended daily intake; MRI or CT scan consistent with a diagnosis of stroke, intracranial bleeding, mass lesion, or normal pressure hydrocephalus (minimal white matter changes and up to 2 lacunar infarcts judged to be clinically insignificant were allowed). Participants who progressed to dementia during the trial could remain in the trial and start approved Alzheimer's disease medication, according to the clinician's judgment (switching to Souvenaid was allowed)</p> <p>Setting: participants were recruited from memory clinics and had routine assessments in the year before screening (not further described)</p> <p>Total number of participants randomised: n = 311 (n = 153 Souvenaid group / n = 158 control group)</p> <p>Per protocol population (24 months): n = 295 (n = 142 Souvenaid group / n = 153 control group)</p> <p>Baseline characteristics:</p> <ul style="list-style-type: none"> <li>• age, mean (SD): Souvenaid group 71.3 (7.0) , control group 70.7 (6.2);</li> <li>• women in percentage: Souvenaid group 47%, control group 54%;</li> <li>• years of education, mean (SD): Souvenaid group 10.6 (3.9), control group 10.7 (3.6);</li> <li>• MMSE, mean (SD): Souvenaid group 26.4 (2.1), placebo group 26.9 (1.9);</li> <li>• no BMI was reported. We asked the project co-ordinator of the study who referred to future publications for baseline data</li> <li>• apolipoprotein e4 positive carrier, n (%): Souvenaid group 83/138 (60), control group 90/143 (63) (not available for all participants)</li> </ul>
Interventions	<p>Intervention 1: Souvenaid 125 ml drink/once daily for 24 months which contains Fortasyn Connect™ (DHA, EPA, phospholipids, choline, UMP, vitamin B12, B6, and folate, vitamins C and E, and selenium) (see <a href="#">Table 1</a>)</p> <p>Intervention 2: Isocaloric drink 125 ml/once daily for 24 months, similar in appearance and flavours (vanilla and strawberry)</p>
Outcomes	<p>Primary (24 months):</p> <ul style="list-style-type: none"> <li>• Cognitive performance based on NTB (<a href="#">Harrison 2007</a>) primary endpoint z-score; 5 components: Consortium to Establish a Registry for Alzheimer's Disease (CERAD) 10-word list learning immediate recall, CERAD 10-word delayed recall, CERAD 10-word recognition, category fluency, and letter digit substitution test (LDST)</li> </ul> <p>Secondary (24 months):</p>

**LipiDiDiet study 2017** (Continued)

- NTB (Harrison 2007) memory domain z-score; 3 components: CERAD10-word list learning immediate recall, delayed recall, and recognition
- NTB (Harrison 2007) executive function domain z-score; 4 components: category fluency, Wechsler memory revised (WMS-r) Digit Span total score, concept shifting test condition C (corrected for the zero trials), letter digit substitution test (LDST)
- NTB (Harrison 2007) total composite z-score based on all 16 items of the NTB)
- The Clinical dementia rating scale-Sum of Boxes (CDR-SOB) (O'Bryant 2008)P
- Progression to dementia (according to DSM IV)

Safety and tolerability

Surrogate parameter (i.e. MRI assessed are not included in this review)

Methods of AE Assessment	<ul style="list-style-type: none"> <li>• Safety parameters: adverse events, concomitant medication, nutritional supplement, study product compliance, vital signs (heart rate, systolic blood pressure, and diastolic blood pressure), and clinical safety laboratory tests</li> <li>• Assessment of product compliance by participants recorded the amount of study product taken in a daily diary; no specification for the other parameters</li> <li>• Monitoring of the parameters over a period of 24 months</li> </ul>
--------------------------	--

Notes Funding and methods used to control bias resulting from conflict of interest: see Table 2.

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p><a href="#">LipiDiDiet study 2017</a>:</p> <p>Quote: "Eligible participants were randomly assigned (1:1) to receive either the active or control product once daily according to a randomisation list, which was computer generated by Nutricia Research, stratified by site, and in block sizes of four." p. 967</p>
Allocation concealment (selection bias)	Low risk	<p><a href="#">LipiDiDiet study 2017</a>:</p> <p>Quote: "Sealed opaque envelopes were available for each participant. After acceptance of a participant to the trial, the envelope with the lowest unused number was opened at the site, containing the code for that participant." p.967</p>
Blinding of participants and personnel (performance bias) All outcomes	Low risk	<p><a href="#">LipiDiDiet study 2017</a>:</p> <p>Quote: "The active and control products were isocaloric and similar in appearance and flavours (vanilla and strawberry). All study personnel and participants, including the investigators and study-site staff, were masked to treatment assignment." p.967</p>
Blinding of outcome assessment (detection bias) All outcomes	Low risk	<p><u>Blinding of efficacy outcomes</u>: appropriate for 24 months data</p> <p><u>Blinding of safety and efficacy interims outcomes</u>: high risk</p> <p><a href="#">LipiDiDiet study 2017</a>:</p> <p>Quote: "All study personnel and participants, including the investigators and study-site staff, were masked to treatment assignment. Only the trial-independent statistician and the independent data monitoring committee, who reviewed interim data for safety and efficacy purposes, were partially unmasked." p.967</p>

**LipiDiDiet study 2017** (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	ITT analysis and sensitivity analysis considering missing data not at random provided
Selective reporting (re-reporting bias)	Low risk	Secondary outcomes for MMSE, ADAS-Cog, MADRS and Alzheimer's Disease Cooperative Study-Activities of Daily Living (ADCS-ADL) were planned in trials registry the study protocol was changed in the same month of trial completion (June 2015) but "prior to database lock" (supplement p.5 to 6). The secondary outcomes were reduced and re-categorised which was justified by new AD research and respective references
Other bias	Low risk	

**S-Connect study 2013**
**Study characteristics**

Methods	Randomised, double-blind, placebo-controlled trial Trial duration from March 2009 to March 2011
Participants	<p>Country: USA</p> <p>Diagnosis: mild-to-moderate Alzheimer's disease (mean MMSE 20)</p> <p>Follow-up: 24 weeks</p> <p>Inclusion criteria: age ≥ 50 years; diagnosis of probable AD (NINCDS-ADRA); MMSE score between 14 and 24 inclusive; use of US Food and Drug Administration-approved AD medication on a stable dose for at least 4 months prior to baseline; and availability of a responsible study partner</p> <p>Exclusion criteria: diagnosis of a neurological/psychiatric disease significantly contributing to cognitive difficulties other than AD; depression; recent use of potent anticholinergic agents, antipsychotics, omega-3 fatty acid-containing supplements and/or oily fish consumption more than twice a week, high-energy or high-protein nutritional supplements or medical foods, vitamins B, C and/or E containing supplements at &gt; 100% of daily value, or other investigational products; recent change in lipid-lowering medications, antidepressants, or antihypertensives; alcohol or drug abuse in the opinion of the investigator; or institutionalisation in a nursing home</p> <p>Setting: participants were recruited from community or clinic setting but not institutionalised in a nursing home</p> <p>Total number of participants: n = 527 (n = 265 Souvenaid group / n = 262 control group)</p> <p>Per protocol population: n = 451 (n = 228 Souvenaid group / n = 223 control group)</p> <p>Baseline characteristics:</p> <ul style="list-style-type: none"> <li>• age, mean (SD): Souvenaid group 76.6 (8.2) , control group 76.9 (8.2)</li> <li>• women in percentage: Souvenaid group 52%, control group 52%;</li> <li>• years of education beyond primary school, mean (SD): Souvenaid group 6.7 (3.6), control group 6.4 (3.5);</li> <li>• MMSE, mean (SD): Souvenaid group 19.5 (3.2), placebo group 19.4 (3.0);</li> <li>• body mass index, kg/m<sup>2</sup> (SD): Souvenaid group 26.2 (4.5), placebo group 26.6 (4.6);</li> <li>• apolipoprotein e4 positive carrier, n (%): Souvenaid group 135 (60.8), control group 116 (58.0);</li> <li>• participants used acetylcholinesterase inhibitor (%): Souvenaid group 87 (32.8), control group 92 (35.1);</li> <li>• participants used memantine (%): Souvenaid group 13 (4.9), control 19 (7.3)</li> </ul>

**S-Connect study 2013** (Continued)

- participants used acetylcholinesterase inhibitor and memantine combined (%): Souvenaid group 164 (61.9), control group 151 (57.6)

Interventions	<p>Intervention 1: Souvenaid 125 mL drink/once daily for 24 weeks which contains Fortasyn Connect™ (DHA, EPA, phospholipids, choline, UMP, vitamin B12, B6, and folate, vitamins C and E, and selenium) (see <a href="#">Table 1</a>). Participants chose vanilla or strawberry flavours based on personal taste preferences</p> <p>Intervention 2: Iso-caloric control product 125 ml/once daily for 24 weeks. Product lacked Fortasyn Connect™, but was otherwise identical to the active product with identical taste profile and appearance. Participants chose vanilla or strawberry flavours based on personal taste preferences</p>
Outcomes	<p>Primary (24 weeks):</p> <ul style="list-style-type: none"> <li>• The Alzheimer's Disease Assessment Scale ADAS-cognitive subscale (ADAS-Cog) (<a href="#">Rosen 1984</a>)</li> </ul> <p>Secondary (24 weeks):</p> <ul style="list-style-type: none"> <li>• The Alzheimer's Disease Cooperative Study-Activities of Daily Living (ADCS-ADL) (<a href="#">Galasko 1997</a>)</li> <li>• Cognitive test battery named Global cognitive function composite z-score; 4 components: Digit Span from the Wechsler Memory Scale – Third Edition, the Concept Shifting Test, the Letter Digit Substitution Test, and Category Fluency</li> <li>• The Clinical dementia rating scale-Sum of Boxes (CDR-SOB) (<a href="#">O'Bryant 2008</a>)</li> <li>• Safety and tolerability</li> </ul> <p>Nutritional blood parameters assessed are not included in this review</p>
Methods of AE Assessment	<ul style="list-style-type: none"> <li>• Safety parameters: examination of participant medical history, (serious) adverse events, concomitant medication, nutritional supplement, study product compliance, vital signs and safety laboratories for liver function, renal function, and coagulation</li> <li>• Assessment not specified</li> <li>• Monitoring of the parameters over a period of 24 weeks</li> </ul>
Notes	Funding and methods used to control bias resulting from conflict of interest: see <a href="#">Table 2</a>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	<p><a href="#">S-Connect study 2013</a>:</p> <p>Quote: "Allocation to active or control product was performed through a central randomization procedure in the Electronic Data Capture system using four different randomization codes (A, B, C, and D)." p. 2</p>
Allocation concealment (selection bias)	Low risk	<p><a href="#">S-Connect study 2013</a>:</p> <p>Quote: "Allocation to active or control product was performed through a central randomization procedure in the Electronic Data Capture system using four different randomization codes (A, B, C, and D)." p. 2</p>
Blinding of participants and personnel (performance bias) All outcomes	Low risk	<p><a href="#">S-Connect study 2013</a>:</p> <p>Quote: "Participants, study partners, and study staff were masked to study group assignment during the trial. Unmasking did not occur until initial statistical modeling of the primary outcome was complete." p. 2</p>
Blinding of outcome assessment (detection bias) All outcomes	Low risk	<p><a href="#">S-Connect study 2013</a>:</p>

**S-Connect study 2013** (Continued)

Quote: "Participants, study partners, and study staff were masked to study group assignment during the trial. Unmasking did not occur until initial statistical modeling of the primary outcome was complete." p. 2

Incomplete outcome data (attrition bias) All outcomes	Low risk	<p>Provided ITT</p> <p>The reasons for discontinuation from 70 participants are unclear apart from SEA but drop outs are balanced in numbers and overall drop out 14% (IG 14%, CG 15%).</p>
Selective reporting (reporting bias)	Low risk	All outcomes reported as described in protocol, study conclusion congruent, with results and relevant AEs/SAEs are named with distribution to group
Other bias	Low risk	The model specifications for the outcomes measured with "trajectories over time" could be resolved by personal communication with the sponsor

**Souvenir II study 2012**
**Study characteristics**

Methods	<p>Randomised, double-blind, placebo-controlled trial</p> <p>Randomisation between November 2009 and May 2011. We got no information on exact trial duration from the Sponsor Nutricia</p>
Participants	<p>Countries: Europe (The Netherlands, Germany, Belgium, Spain, Italy, and France)</p> <p>Diagnosis: "drug-naïve" patients with very mild Alzheimer's disease (mean MMSE 25)</p> <p>Follow-up: 24 weeks</p> <p>Inclusion criteria: diagnosis of probable Alzheimer's disease (NINCDS-ADRA); recent MRI or CT had shown no evidence of any other potential causes of dementia; MMSE <math>\geq</math> 20; age <math>\geq</math> 50 years; written informed consent; and availability of a responsible caregiver</p> <p>Exclusion criteria: neurological disease other than Alzheimer's disease; cholinesterase inhibitor or NMDA-receptor antagonist use within 3 months prior to baseline; Depression Scale (15-item) score of <math>&gt;</math> 6; use within 2 months prior to baseline of: Omega-3 fatty acid containing supplements or regular consumption of oily fish (<math>&gt;</math> twice/week) within 2 months prior to baseline, use of atropine, scopolamine, tolterodine, hyoscyamine, biperiden, benztropine, trihexyphenidyl, oxybutynin, antipsychotics, vitamins B, C, and/or E (<math>&gt;</math> 200% of the recommended daily intake), consumption of high-energy and/or high-protein nutritional supplements, a change in dose of lipid-lowering medications, antidepressants, antihypertensives, or the use of other investigational products within 1 month prior to baseline; excessive alcohol intake or drug abuse; nursing home institutionalisation; investigator uncertainty regarding the willingness or ability of the patient to comply with the protocol</p> <p>Setting: Community; participants recruited from Alzheimer's disease centres (The Netherlands (n = 9), Germany (n = 5), Belgium (n = 4), Spain (n = 3), Italy (n = 3), and France (n = 3))</p> <p>Total number of participants: n = 259 (n = 130 Souvenaid group / n = 129 control group)</p> <p>Per protocol population: n = 238 (n = 118 Souvenaid group / n = 120 control group)</p> <p>Baseline characteristics:</p> <ul style="list-style-type: none"> <li>• age, mean (SD): Souvenaid group 74.4 (6.9), control group 73.2 (8.4)</li> <li>• women in percentage: Souvenaid group 47.7%, control group 50.4%;</li> <li>• years of education beyond primary school, mean (SD): Souvenaid group 6.5 (4.8), control group 6.6 (4.6);</li> </ul>

**Souvenir II study 2012** (Continued)

- MMSE, mean (SD): Souvenaid group 24.9 (2.9), placebo group 25.0 (2.8);
- BMI, kg/m<sup>2</sup> (SD): Souvenaid group 26.1 (4.1), placebo group 26.7 (4.2);
- apolipoprotein e4 positive carrier, n (%): Souvenaid group 59 (48.8), control group 60 (50.8)

Interventions	<p>Intervention 1: Souvenaid 125 mL drink/once daily for 24 weeks which contains Fortasyn Connect™ (DHA, EPA, phospholipids, choline, UMP, vitamin B12, B6, and folate, vitamins C and E, and selenium) (see <a href="#">Table 1</a>)</p> <p>Intervention 2: Iso-caloric control product 125 ml/once daily that lacked Fortasyn Connect™, but that was otherwise identical to the active product with identical taste profile and appearance</p>	
Outcomes	<p>Primary (24 weeks):</p> <ul style="list-style-type: none"> <li>• Based on NTB (<a href="#">Harrison 2007</a>) memory function domain z-score; 5 components: Rey Auditory Verbal Learning Test immediate recall, delayed recall and recognition performance, and Wechsler Memory Scale-revised (WMS-r) verbal paired associates immediate and delayed recall</li> </ul> <p>Secondary (24 weeks):</p> <ul style="list-style-type: none"> <li>• NTB (<a href="#">Harrison 2007</a>) executive function domain z-score; 5 components: WMS-r Digit Span, Trail Making Tests parts A and B (Delis Kaplan Executive Function System™ condition 2 and condition 4, respectively), Category Fluency, and the Controlled Oral Word Association Test</li> <li>• modified NTB (<a href="#">Harrison 2007</a>) total composite z-score; 12 components: Rey Auditory Verbal Learning Test immediate recall, delayed recall and recognition performance, and Wechsler Memory Scale-revised (WMS-r) verbal paired associates immediate and delayed recall, WMS-r Digit Span, Trail Making Tests parts A and B (Delis Kaplan Executive Function System™ condition 2 and condition 4, respectively), Category Fluency, and the Controlled Oral Word Association Test. Additional components: orientation task of the ADAS-cog and the Letter Digit Substitution Test</li> <li>• Disability Assessment for Dementia (DAD) (<a href="#">Gelinis 1999</a>)</li> </ul> <p>Safety and tolerability parameters assessed but not explicitly named as outcomes; Electroencephalography and nutritional blood parameters not included in this review</p>	
Methods of AE Assessment	<ul style="list-style-type: none"> <li>• Safety parameters: examination of participant medical history, adverse events, vital signs and laboratory tests</li> <li>• Assessment of product compliance by participant recorded; no specification for the other parameters</li> <li>• Monitoring of the parameters over a period of 24 weeks</li> </ul>	
Notes	Funding and methods used to control bias resulting from conflict of interest: see <a href="#">Table 2</a>	
<b>Risk of bias</b>		
<b>Bias</b>	<b>Authors' judgement</b>	
<b>Support for judgement</b>		
Random sequence generation (selection bias)	Low risk	<p><a href="#">Souvenir II study 2012</a>:</p> <p>Quote: "Allocation to the study groups was performed using a central randomization procedure in the Electronic Data Capture system, using four different randomization codes (A, B, C, and D)" p. 228</p>
Allocation concealment (selection bias)	Low risk	<p><a href="#">Souvenir II study 2012</a>:</p> <p>Quote: "Allocation to the study groups was performed using a central randomization procedure in the Electronic Data Capture system, using four different randomization codes (A, B, C, and D)." " The investigator, study-site staff, Danone Research staff, study staff of the Clinical Research Organisation, patients, and caregivers were all blinded to the study products." p. 228</p>

**Souvenir II study 2012** *(Continued)*

Blinding of participants and personnel (performance bias) All outcomes	Low risk	<a href="#">Souvenir II study 2012:</a>  Quote: "The investigator, study-site staff, Danone Research staff, study staff of the Clinical Research Organisation, patients, and caregivers were all blinded to the study products." p. 228
Blinding of outcome assessment (detection bias) All outcomes	Low risk	<a href="#">Souvenir II study 2012:</a>  Quote: "The randomization code was not broken until initial statistical modeling of the primary outcome was complete." p. 228  Quote: "Data analysis was conducted by staff of Danone Research and an outside statistician (JWR Twisk) independently and again by staff at Rush Alzheimer's Disease Center (S Leurgans, RC Shah, DA Bennett, W Fan) who received the whole data set and preformed a statistical analysis blinded to study treatment on the primary outcome measure" p. 234
Incomplete outcome data (attrition bias) All outcomes	Low risk	Lost to follow-up 8.1% almost equal distributed
Selective reporting (reporting bias)	Low risk	Outcomes presented as described in published study protocol.
Other bias	Low risk	

AD: Alzheimer's disease; ADAS-Cog: Alzheimer's Disease Assessment Scale -cognitive subscale; ADCS-ADL: Alzheimer's Disease Cooperative Study Activities of Daily Living; AE: Adverse events; BMI: body mass index; CT: computer-assisted tomography; DHA: Docosapentaenoic acid; DSM: Diagnostic and Statistical Manual of Mental Disorders; EPA: Eicosapentaenoic acid; ITT: Intention to treat; MADRS: Montgomery-Åsberg Depression Rating Scale; MMSE: Mini Mental State Examination; MRI: Magnetic resonance imaging; NTB: Neuropsychological Test Battery; NMDA: N-methyl-D-aspartate. SAE: Serious adverse events; SD: Standard deviation; UMP: Uridine-5'-monophosphate

**Characteristics of excluded studies** *[ordered by study ID]*

Study	Reason for exclusion
<a href="#">Souvenir II OLE study 2015</a>	Open-label extension of the <a href="#">Souvenir II study 2012</a> , all participants received the active product
<a href="#">Souvenir I study 2010</a>	Treatment with Souvenaid lasted only 12 weeks

**Characteristics of ongoing studies** *[ordered by study ID]*
**NL-ENIGMA**

Study name	NL-ENIGMA
Methods	Randomised controlled trial
Participants	40 patients with mild cognitive impairment or mild dementia due to Alzheimer's disease
Interventions	Medical food Souvenaid or placebo for a period of 24 weeks
Outcomes	Primary: Quantitative absolute and relative

**NL-ENIGMA** (Continued)

(FDG) uptake over 24 weeks, as assessed by 18F-FDG-PET using Alzheimer's disease regions of interest (ROIs)

Secondary:

- Semi-quantitative Standardized Uptake Value (SUV) and SUV ratio over 24 weeks, assessed by 18F-FDG-PET using Alzheimer's disease Regions of Interest (ROIs) using different time windows after injection
- MRI biomarkers
- Blood biomarkers
- CSF markers (optional)
- Cognition: Rey Auditory Verbal Learning Test immediate and delayed recall and recognition test - Executive functioning using TMT-A and TMT-B

Semi-quantitative Standardized Uptake Value (SUV) and SUV ratio over 24-weeks

Starting date	
Contact information	
Notes	We contacted N. Scheltens and the sponsor Nutricia in April 2019. According to N. Scheltens results will be presented at a conference in 2019. patient-relevant outcomes are only investigated as secondary outcomes in this trial. We therefore decided to wait until the trial is published

CSF: cerebrospinal fluid; MRI: magnetic resonance imaging

**DATA AND ANALYSES**
**Comparison 1. Souvenaid versus placebo in prodromal Alzheimer's disease**

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 Incidence of Alzheimer's dementia	1	311	Risk Ratio (M-H, Fixed, 95% CI)	1.09 [0.82, 1.43]
1.2 Cognition: NTB primary endpoint z-score (five components)	1	275	Mean Difference (IV, Fixed, 95% CI)	0.08 [-0.04, 0.20]
1.3 Cognition: NTB total composite z-score (16 components)	1	274	Mean Difference (IV, Fixed, 95% CI)	0.01 [-0.08, 0.10]
1.4 Specific cognition: NTB memory domain z-score (3 components)	1	274	Mean Difference (IV, Fixed, 95% CI)	0.13 [-0.01, 0.27]
1.5 Specific cognition: NTB executive function domain z-score (4 components)	1	274	Mean Difference (IV, Fixed, 95% CI)	-0.11 [-0.22, 0.01]
1.6 Combined cognitive-function: CDR-SoB	1	230	Mean Difference (IV, Fixed, 95% CI)	-0.56 [-0.95, -0.17]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.7 General safety	1		Risk Ratio (M-H, Fixed, 95% CI)	Subtotals only
1.7.1 Any adverse events	1	309	Risk Ratio (M-H, Fixed, 95% CI)	0.99 [0.91, 1.08]
1.7.2 Any serious adverse events	1	309	Risk Ratio (M-H, Fixed, 95% CI)	1.17 [0.76, 1.81]
1.7.3 Dropout overall	1	309	Risk Ratio (M-H, Fixed, 95% CI)	1.03 [0.67, 1.58]
1.7.4 Dropout due to adverse events	1	309	Risk Ratio (M-H, Fixed, 95% CI)	1.55 [0.57, 4.25]
1.7.5 Dropout due to serious adverse events	1	309	Risk Ratio (M-H, Fixed, 95% CI)	2.07 [0.38, 11.11]

<sup>a</sup>The exact terminology of the subscores is not entirely consistent in the included studies. For example, the memory score is called "NTB memory domain (z-score)" in the [LipiDiDiet study 2017](#) and "Memory function domain score (z-score)" in the [Souvenir II study 2012](#). To make the text easier to read, we have standardised the wording in the continuous text.

<sup>b</sup>The NTB subdomains and the NTB total composite scores used were composed differently in the included trials. In the continuous text we will refer to the number of integrated components and the detailed presentation in [Table 5](#).

<sup>c</sup>The "Global cognitive function composite score (z-score)" from the [S-Connect study 2013](#) is based on the same components as the "NTB executive function domain (z-score)" from the [LipiDiDiet study 2017](#). When reporting the results, we have maintained the classification of the authors as "Composite score" in the [S-Connect study 2013](#) and "Executive function score" in the [LipiDiDiet study 2017](#).

ADAS-cog: Alzheimer's Disease Assessment Scale - Cognitive subscale; CERAD: Consortium to Establish a Registry for Alzheimer's Disease; COWAT: Controlled Oral Word Association Test; CST: Concept Shifting Test; RAVLT: Rey Auditory Verbal Learning Test; TMT: Trail Making Test; WMS: Wechsler Memory Scale; WMS-r: Wechsler Memory Scale Revised Edition; WMS-VPA: Wechsler Memory Scale Verbal Paired Associates

## HISTORY

Protocol first published: Issue 5, 2015

Review first published: Issue 12, 2020

## CONTRIBUTIONS OF AUTHORS

MB: correspondence; project management, drafting review versions; selection of randomised controlled trials (RCTs); extraction of data; assessing risks of bias; data entry, data analysis; GRADE; interpretation of data/analyses.

AF: selection of RCTs; extraction of data; assessing 'Risk of bias' data entry, data analysis; interpretation of data/analyses.

AW: interpretation of data/analyses.

GL: GRADE; interpretation of data/analyses.

SW: description of condition section, interpretation of data/analyses.

MB wrote the remaining sections of the review, which were complemented and commented by all authors.

## DECLARATIONS OF INTEREST

Marion Burckhardt - none known.

Andreas Wienke - none known.

Astrid Fink - none known.

Stefan Watzke - none known.

Gero Langer - none known.

## SOURCES OF SUPPORT

### Internal sources

- Roux Program of Martin-Luther University Halle-Wittenberg, Medical Faculty, Germany  
University Grant

### External sources

- NIHR, UK

This review was supported by the National Institute for Health Research (NIHR), via Cochrane Infrastructure funding to the Cochrane Dementia and Cognitive Improvement group. The views and opinions expressed therein are those of the authors and do not necessarily reflect those of the Systematic Reviews Programme, NIHR, National Health Service or the Department of Health

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

In our protocol ([Burckhardt 2015](#)), we listed combined cognitive-functional measures like the CDR under the primary outcome 'Dementia severity measures'. However, these measures are not used exclusively to stage dementia severity. We therefore changed the outcome to 'Combined cognitive-functional outcomes'.

We deviated from our plan to rate all outcomes with a consumer group for GRADE. In another review conducted by our group ([Burckhardt 2016](#)), we experienced very low variance within the ratings of the outcomes which we attributed to the low number of rating participants. In consideration of this and our limited resources, we did not further prioritise the predefined outcomes for this review.

In the protocol we have written that we would investigate the adverse effects as a primary outcome. In order to be able to present the safety aspects of the study products with favourable and unfavourable outcomes in a balanced way, as well as to take account of reporting standards of potential harms, we have extended this primary outcome to adverse events and adverse effects.

We intended to present the proportion of individuals with changes in the scale measures of the primary outcomes (i.e. more or less than four scale points for ADAS-cog) if data were available. However, considering variable scale measures and non-significant effects within the primary outcomes of the trials, we did not request those data from the study authors.

We performed none of the predefined meta-analyses, sensitivity analyses or subgroup analyses, due to a lack of data. We presented all outcomes grouped by the stage of AD.

Max Herke and Tobias Wustman contributed to the protocol of this review, but left the team for personal reasons. Andreas Wienke joined the team for this review.

## INDEX TERMS

### Medical Subject Headings (MeSH)

Alzheimer Disease [\*diet therapy]; Bias; Cognition; Dementia [prevention & control]; \*Dietary Supplements [adverse effects]; Disease Progression; Docosahexaenoic Acids [adverse effects] [chemistry] [\*therapeutic use]; Eicosapentaenoic Acid [adverse effects] [chemistry] [\*therapeutic use]; Phospholipids [adverse effects] [chemistry] [\*therapeutic use]; Placebos [therapeutic use]; Prodromal Symptoms; Randomized Controlled Trials as Topic; Time Factors
