**Abstract:** Peripheral T-cell lymphomas (PTCLs) represent a heterogeneous group of rare hematologic malignancies accounting for less than 10% of non-Hodgkin lymphomas. The 2016 classification of World Health Organization recognized 29 different entities of PTCLs. These subgroups are characterized by different molecular and genetic patterns. For nearly 30 years, little improvement in the treatment of PTCLs has been noticed due to the paucity of randomized trials and anthracycline-based chemotherapy remains the mainstay of first-line treatment. In front-line setting, ECHELON-2, the first randomized controlled Phase III clinical trial, recently met its primary endpoint of PFS demonstrating the superiority of BV containing regimen when compared to standard CHOP in patients with CD30 positive PTCLs. The role of therapeutic intensifications such as autologous or allogenic stem cell transplantations remains controversial in first-line setting and in relapsed/refractory disease due to the lack of studies clearly addressing this question and the recently published negative studies. PTCLs are often refractory to first-line chemotherapy and tend to relapse after an initial response. New agents have been approved for relapsed/refractory disease such as Histone deacetylase inhibitors, folate analogue metabolic inhibitor or CD30 antibody drug conjugated. Despite an acceptable response to these agents, progression-free survival remains very poor. New strategies such as combinations of different agents have been evaluated in order to improve outcomes. Innovative drugs in the fields of epigenetics, immunomodulation within the tumor microenvironment, and direct targeting of tumor cells to CD30 and T-cell receptor abnormalities open new perspectives to improve the treatment of PTCLs.

**Keywords:** peripheral T-cell lymphomas, brentuximab vedotin, HDAC inhibitors, immune checkpoint inhibitors, CHOP, stem cell transplantation

## Introduction

Peripheral T-cell Lymphomas (PTCLs) represent a relatively rare disease accounting for 6–10% of all cases of non-Hodgkin lymphomas (NHLs) in western countries.<sup>1</sup> The incidence of PTCLs exhibits a geographical dependence, reaching 20–25% of NHLs in some parts in Asia and South America.<sup>2</sup> PTCLs constitute a heterogeneous group of hematologic malignancies that differ in clinical behavior and anatomical location. The World Health Organization (WHO) recognizes at least 29 distinct entities of mature post thymic T-cell NHLs in the updated classification of hematological and lymphoid neoplasms.<sup>3</sup> The last classification proposed several provisional subtypes and introduced the T-follicular helper (TFH) phenotype. TFH lymphoma and nodal T-cell lymphoma with TFH phenotype are thus separate subtypes different from PTCLs not otherwise specified (PTCL-NOS). PTCLs could be anatomically classified as nodal, extranodal, cutaneous and leukemic

forms (Table 1). The most frequent subtypes are PTCL-not otherwise specified (NOS) (30% of PTCLs), angioimmunoblastic T-cell lymphoma (AILT; 15–30% of PTCLs), anaplastic large T-cell lymphoma (ALCL; 15% of PTCLs), extranodal natural killer (NK) cell/T cell lymphoma (ENKTCL; 10% of PTCLs), and intestinal T cell lymphomas (~5–6% of PTCLs, including enteropathy-

associated T cell lymphoma (EATL) and monomorphic epitheliotropic intestinal T cell lymphoma (MEITL).<sup>4</sup> Adult T-cell leukemia/lymphoma (ATLL) is most commonly diagnosed in countries with a high prevalence of human T-cell lymphotropic virus type 1 (HTLV-1) infection, especially in Japan and the Caribbean.<sup>5</sup> The intrinsic variability of PTCLs and their scarcity had stymied progress in the treatment outcome. Despite the recent major advances in the understanding of PTCLs, including new laboratory methods for diagnosis and new therapeutic approaches, the prognosis of the majority of PTCLs remains poorer than with aggressive B-cell lymphoma, except for anaplastic lymphoma kinase (ALK)-positive ALCL. The 5-year overall survival (OS) for ALK+ ALCL, ALK- ALCL, AITL, and PTCL-NOS is 80.2%, 44.7%, 35.4%, and 25.4%, respectively.<sup>6</sup> This review aims to discuss the molecular and genetic patterns of PTCLs, first-line treatment including bone marrow transplantation, as well as treatment of relapsed/refractory PTCLs and future therapeutic directions.

## Molecular and Genetic Patterns of PTCLs

As previously mentioned, there are 29 different subtypes of PTCLs according to the 2016 WHO classification. PTCL-NOS harbors no specific characteristic immunophenotype. However, two subgroups have been identified using the Gene Expression Profiles (GEPs) with different gene expression driven by the transcription factors TBX-21 or GATA-3. The GATA-3 PTCL-NOS subgroup has significantly poor survival outcomes.<sup>7,8</sup>

Patients with ALK+ ALCL most frequently present t(2;5) that fuses nucleophosmin gene (NPM) with the ALK gene leading to an oncogenic tyrosine kinase (NPM-ALK) that promotes signaling of the JAK/STAT pathway. GEPs showed hyperactivation of STAT3 in ALCL caused mainly by ALK rearrangements or activating mutations in the JAK/STAT pathway. Based on rearrangements revealed by cytogenetics, ALK negative patients could be classified into three groups: DUSP22 +, TP63 +, and triple negative group (ALK-, DUSP22- and TP63-). ALK-negative ALCLs have chromosomal rearrangements of DUSP22 or TP63 in 30% and 8% of the cases respectively. DUSP22-rearranged cases have favorable outcomes similarly to ALK+ ALCLs, whereas other genetic variants have inferior outcomes.<sup>9</sup>

The molecular profiling of other PTCLs revealed several mutations of genes involved in DNA methylation such as

TET2, IDH2 and DNMT3.<sup>10</sup> TET2 mutations have been described in 47% of patients with AITL, and in 38% of patients with PTCL-NOS. This high incidence in PTCL-NOS is probably related to the TFH phenotype being included in this subgroup in the previous 2008 WHO classification.<sup>11</sup> Furthermore, 76% of patients with AITL have TET2 mutations.<sup>10</sup> DNMT3A mutations occurred in 33% of patients with AITL, and are frequently associated with TET2 mutations (100% of the patients with reference to Odejide et al). IDH2 mutations, initially reported in patients with acute myeloid leukemia (AML) and Glioblastoma Multiforme, had also been found in 20 to 45% of patients with AITL, and were detected in different loci.<sup>12</sup> Moreover, IDH2 mutations co-occur frequently with TET2 mutations.<sup>10</sup> These mutations are highly reported in patients with AITL (67%), and less frequently in patients with PTCL-NOS (18%). RHOA mutations do not seem to have an epigenetic influence, despite being associated with T-cell proliferation and invasiveness.<sup>13,14</sup> GEPs revealed multiple mutations in patients with ATLL such as RHOA, TET2, loss-of-function mutations in TP53, and overexpression of PD-L1.<sup>15</sup>

Other interesting mutations in PTCLs are those affecting T-cell receptor (TCR)-related genes such as PLCG1 (14%), CD28 (9%, exclusively in AITL), PI3K elements (7%), CTNNA1 (6%), and GTF2I (6%). More importantly, most variants in TCR-related genes represent gain-of-function mutations that could be addressed by new potential drugs.<sup>16</sup>

Activating mutations in TCR pathway genes had also been reported especially in patients with AITL and PTCL-NOS leading to lymphomagenesis by activating NF- $\kappa$ B pathway. The most common mutation leads to PLCG1 and was also described in CTCL.<sup>17</sup>

## First-Line Treatment of PTCLs

Due to the paucity of randomized clinical trials in this setting, no clear gold standard exists for the treatment of patients with newly diagnosed PTCLs. Treatment regimens are extrapolated from those initially developed in aggressive B-cell lymphoma. CHOP (cyclophosphamide, Adriamycin, vincristine and prednisolone) or CHOP-like regimens have been widely considered as the standard of care in patients with newly diagnosed PTCLs. Controlled studies are rare and the largest studies in PTCLs are retrospective. Up to one-third of patients with PTCLs may progress during first-line treatment.<sup>18</sup> The adoption of CHOP regimen was initially based on the results of a large randomized phase III clinical trial of patients with high-grade and/or advanced stage B-cell or T-cell NHLs. This study compared CHOP with more dose-dense regimens (MACOP-

B, ProMACE-CytaBOM and m-BACOD), and failed to demonstrate a significant benefit when compared to CHOP.<sup>19</sup> Reyes et al found that ACVBP was superior to CHOP in patients with low-risk localized aggressive lymphoma.<sup>20</sup> More intense chemotherapy regimens such as hyperCVAD (hyperfractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone followed by methotrexate and cytarabine) and DA-EPOCH (dose-adjusted etoposide, prednisone, vincristine, cyclophosphamide, doxorubicin, and rituximab) showed good results in terms of response rate and progression-free survival (PFS), but at the cost of higher myelosuppression rates leading to poor treatment adherence and early deaths.<sup>21,22</sup> Retrospective and non-randomized studies suggested that the addition of etoposide to CHOP (CHOEP) in young and fit patients could be associated with a better outcome.<sup>23,24</sup>

More recently, the results of the first multicenter, double blind, randomized, placebo-controlled phase III trial in PTCLs were reported. The ECHELON-2 compared brentuximab vedotin (BV), cyclophosphamide, doxorubicin and prednisone (BV + CHP) with the standard CHOP regimen in previously untreated CD30+ PTCLs. The study met its primary endpoint of PFS, demonstrating the superiority of BV containing regimen. At a median follow-up of 36 months, BV + CHP was associated with significantly longer PFS than CHOP: 48.2 months (95% CI, 35.2-not reached) vs 20.4 months (95% CI, 12.7–47.6), with a hazard ratio 0.71 (95% CI, 0.54–0.93,  $p=0.0110$ ). The 3-year PFS rate was 57.1% (95% CI, 49.9–63.7%) for the BV + CHP arm versus 44.4% (95% CI, 37.6–50.9%) for the CHOP arm. The two groups had similar adverse events, including incidence and severity of febrile neutropenia (41 [18%] patients in the BV + CHP group and 33 [15%] in the CHOP group) and peripheral neuropathy (117 [52%] in the BV + CHP group and 124 [55%] in the CHOP group).<sup>25</sup> In addition, more than 70% of patients included in the trial had ALCL including ALK+ or ALK- disease, an entity characterized by high expression of CD30. Importantly, the inclusion criteria of the ECHELON-2 trial required an expression of at least 10% of CD30 on tumor cells. Based on the results of this trial, The Food and Drug Administration (FDA) approved the BV + CHP regimen in patients with CD30+ PTCLs in November 2018.<sup>26</sup> Nowadays, most experts recognize BV + CHP treatment as standard of care for patients with any level CD30+ ALCL. However, the debate concerning the extrapolation of the results to other histologic subtypes continues since the ECHELON-2 trial was not powered enough to answer this question by performing histology-based subgroup analysis. In fact, the European Medicines Agency (EMA) restricted

the approval of BV + CHP to the patients with CD30+ systemic ALCL only.

Histone deacetylase inhibitor (HDACi) romidepsin can be combined with CHOP in the first-line setting.<sup>27</sup> It has been investigated in a phase III randomized double-blind trial in comparison with standard CHOP. The addition of romidepsin to CHOP did not improve PFS, the primary endpoint of the study. In addition, response rates and OS were similar with the combination.<sup>28</sup> Other combinations are ongoing in for previously untreated PCTLs patients, and are summarized in Table 2.

## Autologous Stem Cell Transplantation in Upfront Setting

The role of autologous stem cell transplantation (ASCT) in patients with PTCLs is controversial due to limited data, heterogeneous populations in the current studies, and the lack of randomized trials clearly evaluating ASCT procedure. ASCT has been investigated to prevent the high relapse rate in

chemosensitive patients.<sup>29</sup> The largest prospective studies based on cohort or registry were conducted by the Nordic Lymphoma Group, the German Group, Lysa French group, and United States of America group. The Nordic Lymphoma Group trial enrolled 160 patients with a confirmed diagnosis of PTCLs excluding those with ALK+ ALCL. Patients received 6 cycles of biweekly CHOEP-14 except for those aged 60 years and older who received CHOP-14. One hundred fifteen patients underwent ASCT. At a median follow-up of 60.5 months, OS rate was 51% and PFS rate was 44%. Patients with ALK<sup>-</sup> ALCL had the highest OS and PFS (70% and 61%, respectively) compared with other histological subtypes (PTCL-NOS, AITL and EATL). The differences between the four groups were not statistically significant.<sup>30</sup> In the German study, the second largest prospective trial reported by Reimer et al, 83 patients with newly diagnosed PTCLs were enrolled. Patients received 4 to 6 cycles of CHOP followed by mobilization, and those who were in CR or PR underwent myeloablative chemo-radiotherapy (fractionated total-body irradiation

**Abbreviations:** PFS, progression-free survival; CR, complete response; PR, partial response; DLT, dose-limiting toxicity; TEAE, treatment-emergent adverse events; ORR, objective response rate; SD, stable disease; PD, progressive disease; HSCT, hematological stem cell transplantation; ASCT, autologous stem cell transplantation; SCT, stem cell transplantation; PO, per os; IV, intravenously.

and high-dose cyclophosphamide) and ASCT. Fifty-five (66%) of the 83 patients received transplantation. The main reason for not receiving ASCT was progressive disease. At a median follow-up of 33 months, the estimated 3-year OS was 48% for the intention-to-treat population. Failure to achieve CR was associated with markedly inferior results.<sup>31</sup> More recently, the role of up-front ASCT in PTCLs for responders after induction was reported by the French LYSA study. Two hundred sixty-nine patients were analyzed; they had mostly PTCL-NOS, AITL, or ALK+ ALCL with partial (N = 52, 19%) or complete response (N = 217, 81%) after induction. One hundred and thirty-four patients were allocated to ASCT in ITT, and 135 were not. The median PFS was 3.7 years, and the median OS was 8.4 years for the entire cohort. No OS difference was observed according to histological subtype. The authors failed to depict a survival advantage in favor of ASCT as a consolidation procedure for patients who responded after induction. Subgroup analyses did not reveal any further difference for patients with respect to response status, stage disease, or risk category.<sup>29</sup> Moreover, a large multi-center prospective study was reported from the COMPLETE registry (Comprehensive Oncology Measures for Peripheral T-cell Lymphoma Treatment). This cohort compared the survival outcomes in patients with nodal PTCLs who received or not consolidative ASCT in the upfront setting. The authors did not find any statistical difference in terms of survival between the ASCT and non-ASCT groups. They also suggested that subgroups of patients with nodal PTCLs, especially those with AITL and/or high-risk features (advanced-stage disease or intermediate-to-high IPI scores), might benefit from consolidative ASCT in terms of initial complete response.<sup>32</sup>

Collectively, these results did not sufficiently support the use of ASCT for up-front consolidation in patients with PTCLs in complete or partial response after induction therapy. The role of consolidative ASCT after first remission needs to be defined in prospective randomized trials.

## Autologous Stem Cell Transplantation in Relapsed PTCL Setting

Evidence for ASCT in the relapsed/refractory (R/R) setting is scarce and comes from registry data and retrospective studies. The results suggest that the outcomes could be improved with the use of consolidation HSCT, with the most benefiting group being the ALCL subtype, reaching a 3-years OS of 50% and a PFS of 65%.<sup>33</sup> Data from the CIBMTR registry revealed no significant difference in

survival between ASCT and allogeneic stem cell transplantation (SCT), although a 34% TRM was reported with allogeneic SCT by contrast to only 6% with ASCT.<sup>34</sup> All these results show that SCT could be considered for eligible patients in the salvage setting and in chemotherapy-sensitive patients who have never had it before.

## Allogeneic Stem Cell Transplantation

The role of allogeneic SCT has been investigated recently by a randomized Phase 3 trial comparing ASCT and allogeneic SCT as part of first-line therapy in poor-risk PTCL patients.<sup>35</sup> Patients received conventional chemotherapy with 4 cycles of CHOEP and 1 cycle of DHAP followed by intensification. Patients were randomized to receive BEAM followed by ASCT or myeloablative conditioning (fludarabine, busulfan, cyclophosphamide) followed by allogeneic SCT from a matched related or unrelated donor. One hundred and three patients were enrolled (ASCT: 54, allogeneic SCT: 49), of whom 36 (35%) could not proceed to transplantation mostly due to early disease progression. The 3-year event-free survival (EFS) and OS did not significantly differ between allogeneic SCT and ASCT (EFS: 43% vs 38%,  $p=0.58$ , and 57% vs 70%,  $p=0.41$  respectively). However, the treatment-related mortality (TRM) after allogeneic SCT was 31%, with no reported deaths after ASCT. In younger patients with T-cell lymphoma, standard chemotherapy consolidated by either autologous or allogeneic transplantation result in comparable survival, thus eliminating a role for allogeneic stem cell transplantation in the first-line setting.<sup>35</sup> These results are in line with the retrospective analysis of the MD Anderson Cancer Center for patients with PTCLs that failed to show any difference in outcomes between ASCT and allogeneic SCT. In addition, a CR prior to SCT initiation was associated with improved outcomes.<sup>36</sup>

In a prospective Phase II trial, Corradini et al evaluated the graft-versus-lymphoma effect of reduced-intensity conditioning (RIC) (thiotepa, cyclophosphamide and fludarabine) followed by allogeneic SCT in relapsed PTCLs. Seventeen patients were enrolled, of whom two had chemo-refractory disease and 15 had relapsed disease. Eight patients (47%) had disease relapse after ASCT. Salvage therapy consisted of 4 to 6 cycles of DHAP followed by RIC and allogeneic SCT. At a median follow-up of 28 months, the estimated 3-year OS and PFS rates were 81% and 64% respectively, and the transplantation-related mortality rate was 12%. Donor lymphocyte infusions induced a response in two patients progressing after

transplantation, suggesting the existence of a graft-versus-lymphoma effect.<sup>37</sup>

Zain et al retrospectively reported the results of a case series of patients with R/R PTCLs, undergoing related or unrelated donors' allogenic SCT between 2000 and 2007. Thirty-seven pretreated patients were enrolled, 68% (25 patients) of whom had either relapsed or progressive disease. All patients were ineligible for ASCT. Thirteen patients received fully ablative conditioning regimens, while 24 patients underwent reduced-intensity conditioning. The 5-year OS and PFS were 52.2% and 46.5%, respectively. At the time of analysis, nine (24.3%) patients had either relapsed (n = 6) or progressed (n = 3) post allogenic SCT. At 5 years, the cumulative incidences of non-relapse and relapse/progression mortality were 28.9% and 24.3%, respectively. There were no statistically significant predictors for survival or relapse by univariate Cox regression analysis of disease and patient characteristics; differences between CTCL and other histologies were not significant. The relapse/progression curves reached and maintained a plateau after 1 year post-

transplant, demonstrating that long-term disease control is possible after allogenic SCT in patients with PTCLs with advanced disease.<sup>38</sup> Collectively, these results indicate that allogenic SCT remains an option in patients with R/R PTCLs.

## Treatment of Relapsed/Refractory PTCLs

### Approved Treatment for PTCLs

In relapsing patients, the subsequent treatment is not clearly defined. Conventional chemotherapy and/or autologous or allogenic SCT may result in disease control in a small number of patients. New drug development is the most promising way to improve survival for patients with R/R disease. Over the past decade, the FDA approved 4 new agents for the treatment of R/R PTCLs: pralatrexate, romidepsin, belinostat, and brentuximab vedotin. Two other drugs are approved in China and Japan. These molecules showed a single-agent activity based on the results of published phase II trials summarized in Table 3. However, the EMA did not recognize pralatrexate, romidepsin, and belinostat for the treatment of patients with PTCLs. In

fact, these agents were associated with a good response rate, yet the PFS remains largely unchanged in this high risk group of patients.

### Folate Analogue Metabolic Inhibitor

Pralatrexate, a novel folate analogue metabolic inhibitor with high affinity for reduced folate carrier type 1 (RFC-1), was the first drug approved for the treatment of relapsed and/or refractory PTCLs in September 2009 based on the results of the PROPEL study (Pralatrexate in Patients with Relapsed or Refractory Peripheral T-Cell Lymphoma). Pralatrexate was given intravenously weekly at a dosage of 30mg/m<sup>2</sup> for 6 weeks in a 7-week cycle. The ORR was 29%.<sup>39</sup> Maruyama et al reported the results of a Japanese phase I/II trial evaluating pralatrexate in 20 patients with R/R PTCLs. The ORR was 45%, including two CR; median PFS was 150 days. The median duration of response (DOR) and OS were not reached, and the safety profile was comparable to the PROPEL study.<sup>40</sup> More recently, Hong et al published the outcomes of a single-arm multicenter study of 71 patients with R/R PTCLs after a median of two previous treatment lines. The ORR was 52% with a median DOR of 8.7 months, median PFS of 4.8 months, and median OS of 18.0 months.<sup>41</sup> This suggests that earlier treatment with pralatrexate may be associated with better clinical outcome.

### HDAC Inhibitors

Romidepsin is a bicyclic class 1 selective HDAC inhibitor. It has been isolated from *Chromobacterium violaceum*. In June 2011, the FDA approved romidepsin for the treatment of patients with R/R PTCLs who have progressed after at least one systemic therapy regimen. In a phase II trial conducted by the National Cancer Institute, the ORR with romidepsin in patients with R/R PTCLs was 38%, and the median DOR was 8.9 months.<sup>42</sup> The pivotal registration-directed phase II trial enrolled 130 patients who were treated with romidepsin 14mg/m<sup>2</sup> intravenously on days 1, 8 and 15 every 28-day cycle. Coiffier et al reported an ORR of 25% including 15% CR/CRu (unconfirmed CR) with a median PFS of 4 months and median DOR of 28 months among responders, leading to an accelerated FDA approval.<sup>43</sup>

Belinostat, a hydroxamic acid-derived pan-class I and II HDAC inhibitor, has also been approved by the FDA in July 2014 for the treatment of patients with R/R PTCLs who failed at least one previous treatment line. This was based on the results of the pivotal phase II BELIEF trial,

a multicenter open label trial of belinostat in patients with relapsed or refractory T-cell lymphoma. A total of 129 patients were enrolled and received 1000mg/m<sup>2</sup> of belinostat on days 1–5 in 21-day cycles. The median number of previous treatment lines was 2, and the authors reported an ORR of 25.8% including 10.8% CRs. Patients with PTCL-NOS achieved an ORR of 23%, those with AITL had an ORR of 46%, and patients with ALK-ALCL had an ORR of 15%. The median DOR, PFS and OS were 13.6 months, 1.6 months, and 7.9 months, respectively.<sup>44</sup>

Chidamide is an oral class I/II HDAC inhibitor that has been studied in a pivotal Chinese phase II trial in patients with R/R PTCLs (mainly PTCL-NOS, ALCL, ENKTL, and AITL). Eighty-three patients had been enrolled and received chidamide 30 mg orally twice per week. The ORR was 28% including 14% of CR/CRu. The median PFS was 2.1 months and the median OS was 21.4 months.<sup>45</sup> Based on these results, chidamide was approved only in China for the treatment of patients with R/R PTCLs.

### CD30 Antibody Drug Conjugated

Brentuximab vedotin is the fourth drug approved by the FDA for the treatment of patients with R/R ALCL in August 2011, and extended for primary CTCL and CD30-expressing Mycosis Fungoides in November 2017. In a pivotal phase II trial, BV was evaluated for patients with R/R systemic ALCL. It was administered intravenously as single-agent at a dose of 1.8mg/kg every 3 weeks for up to 16 cycles. Fifty-eight patients were enrolled; the ORR was 86% with 57% of CR, and the median PFS was 13.6 months. Among patients who achieved CR, 5-year OS was 79% and 5-year PFS was 57%.<sup>46</sup> These data led to approval of BV in the USA, European Union, and Japan for patients with sALCL. Many ongoing trials are evaluating the combination of BV with other drugs in both relapsed and upfront settings.

### Chemokine Receptor 4 (CCR4) Monoclonal Antibody

Mogamulizumab is a defucosylated humanized IgG1 monoclonal antibody that targets CC chemokine receptor 4 (CCR4) which is mainly expressed in ALK-ALCL, PTCL-NOS, AITL, and transformed mycosis fungoides. It was approved in Japan for patients with R/R CCR4+ ATLL and cutaneous T-cell lymphoma based on the results of a multicenter phase II trial evaluating mogamulizumab for the treatment of patients with relapsed ATLL. The

study enrolled 28 patients who received intravenous infusions of mogamulizumab once per week for 8 weeks at a dose of 1.0 mg/kg. The ORR was 50% including 30% of CR. Median PFS and OS were 5.2 months and 13.7 months, respectively.<sup>47</sup> Furthermore, mogamulizumab was approved in the USA for the treatment of R/R mycosis fungoides and Sezary syndrome.

## Agents Investigated in R/R PTCLs

### ALK Inhibitors

Crizotinib, an oral ALK-ROS1-MET inhibitor, was associated with an ORR of 90% in a pediatric study of 26 patients having R/R ALK+ ALCL with a good safety profile. Among the 23 patients who achieved a response, 39% maintained their response for at least 6 months, and 22% maintained their response for at least 12 months.<sup>48</sup> Crizotinib was approved by the FDA for the treatment of patients with R/R ALK+ ALCL in children and young adults in January 2021.

### PI3 Kinase and mTOR/AKT Inhibitors

Duvelisib, an oral PI3K-delta-gamma inhibitor was associated with an ORR of 50% in PTCL, and 31.6% in CTCL with 3 complete responses in a phase II trial when used as monotherapy for patients with R/R PTCLs.<sup>49</sup> Everolimus, an oral mammalian target of rapamycin (mTOR) pathway inhibitor, given at 10 mg daily continuously resulted in an ORR of 44% in a phase II trial of 16 patients with R/R PTCL. The median PFS was 4.1 months and the median OS was 10.2 months. Six patients (38%) required a dose reduction to 5mg daily.<sup>50</sup>

### Hypomethylating Agents

Hypomethylating agents (HMAs), initially approved for the treatment of AML and myelodysplastic syndrome, have been studied in R/R PTCLs. HMAs are the pharmacologic counterbalance of epigenetics modified tumor by IDH2, TET2 and DNMT3A mutations.<sup>12</sup> 5-Azacitidine used as monotherapy at a dose of 75 mg/m<sup>2</sup> subcutaneously for 7 consecutive days every 28-days cycle in patients with AITL was associated with an ORR of 75% (9/12) and CR rate of 50% (6/12). Patients presented durable responses with a median PFS and OS of 15 and 21 months, respectively.<sup>51</sup> An ongoing phase III trial is comparing oral 5-Azacitidine with investigator's choice therapy (romidepsin, bendamustine or gemcitabine) in patients with R/R AITL (NCT03593018).

### Immunomodulatory Agent

Lenalidomide, an immunomodulatory agent targeting cereblon and aiolos/ikaros transcription factors and approved in B-cell NHL and multiple myeloma, has shown modest activity when used as monotherapy in the EXPECT phase II trial with an ORR of 22%.<sup>52</sup> In patients with R/R ATLL, lenalidomide demonstrated clinically meaningful antitumor activity with an ORR of 42% including 4 CR and 1 unconfirmed CR in a multicenter phase II trial.<sup>53</sup>

## Immune Checkpoint Inhibitors

Programmed death-ligand 1 (PD-L1) was mainly detected in AITL (>90%) and PTCL-NOS (30–60%), and rarely in other subtypes.<sup>54</sup> In NKTCL, PD-L1 expression ranged between 56 and 93% in different studies, while PD-1 level was consistently low.<sup>55</sup> In addition, Kataoka et al demonstrated that PD-L1 amplifications represent a strong genetic predictor of worse outcomes in patients with both aggressive and indolent ATLL.<sup>56</sup> The efficacy of nivolumab, a PD-1 inhibitor, was evaluated in a Phase I, open-label, dose-escalation, cohort expansion trial for the treatment of patients with R/R TCL. Twenty-three patients were enrolled. The ORR among these patients was 17%.<sup>57</sup> In a retrospective case series, pembrolizumab, another PD-1 inhibitor, showed high efficacy (100%) in 7 patients with R/R NK/T cell lymphoma that relapsed after treatment with L-asparaginase. Complete response was observed in 5 patients (71%), and this was sustained after a median follow-up of 6 months.<sup>58</sup> In a multicenter single-arm phase II trial, pembrolizumab given at a dosage of 200mg intravenously every three weeks, was evaluated for patients with R/R PTCLs. Of 18 enrolled patients, 13 were evaluable for the primary endpoint. The ORR was 33%, with 4 patients showing a CR. The median PFS was 3.2 months and the median OS was 10.6 months. The median duration of response was 2.9 months. Two of the 4 patients who presented CR remained in remission for at least 15 months. The trial was halted early after a preplanned interim futility analysis.<sup>59</sup> PD-1 inhibitors had modest activity when used as monotherapy and these drugs could be more active when combined with another agent such as HDAC inhibitors, HMAs, or antifolates. Table 4 summarizes the major clinical trials evaluating novel combinations of immunotherapy in R/R PTCLs.

## Selected Interesting Combinations in R/R PTCLs

A new strategy was adopted for the treatment of patients with R/R PTCLs based on the combination of approved

**Table 4** Novel Combinations of Immunotherapy Under Investigation in R/R PTCLs

| Agent(s)   | ClinicalTrials.gov | Phase | N   | Treatment   | Primary Endpoint(s)  |
|--|--------------------|-------|-----|---|--|
| Pembrolizumab + romidepsin                                   | NCT03278782        | I/II  | 39  | Romidepsin IV on days 1 and 8 and pembrolizumab IV on day 1. **Abbreviations:** ORR, objective response rate; CR, complete response; DOR, duration of response; PFS, progression-free survival; OS, overall survival; AE, adverse events.

and non-approved medications in the field. Available data concerning these combinations are summarized in Table 5. However, most of these data are reported from small single-center studies without central pathology review.

### Romidepsin Plus Pralatrexate

Romidepsin is an HDAC inhibitor approved for R/R PTCLs. In preclinical models of PTCLs, romidepsin and pralatrexate showed a potent synergy in in-vitro and in-vivo models at dose levels of 50% of the maximal tolerated dose (MTD).<sup>60</sup> Amengual et al reported the results of the first Phase I trial evaluating the combination of these two drugs to determine the MTD, pharmacokinetic profile, and response rate. Pralatrexate 25mg/m<sup>2</sup> and romidepsin 12 mg/m<sup>2</sup> administered concurrently every other week were recommended for the Phase 2 trial. In this phase I study, the ORR for all patients was 57% (13/23), whereas the response rate in patients with PTCLs was 71% (10/14), and 33% (3/9) in patients with B-cell lymphoma.<sup>61</sup> The phase II trial is still ongoing (NCT01947140).

### Romidepsin Plus 5-Azacitidine

The combination of HDACi and HMAs could be a novel approach for the treatment of PTCLs, targeting the epigenetic dysregulation of the disease. Marchi et al demonstrated a marked synergy between HDACi and HMAs in preclinical models of PTCLs.<sup>62</sup> The encouraging results of a multicenter phase I trial evaluating the combination of romidepsin and oral 5-Azacitidine in R/R PTCLs were recently reported. The ORR for all patients was 32%, for non-TCL was 10%, and 73% for patients with T-cell lymphoma. The CR rates were 23%, 5% and 55%, respectively. The MTD retained for phase 2 trial was 5-Azacitidine 300mg on days 1 to 14 and romidepsin 14mg/m<sup>2</sup> on days 8, 15 and 22 of a 35-day cycle.<sup>63</sup> The phase II trial is still ongoing (NCT01998035).

### Romidepsin and Duvelisib

A novel interesting combination in the treatment of R/R PTCLs is the association of HDACi and duvelisib. The results of the phase I/II trial evaluating the association of

duvelisib and romidepsin were reported in an abstract form by Horwitz et al. The MTD of duvelisib was 75mg BID on days 1 to 28, given with romidepsin 10mg/m<sup>2</sup> on days 1, 8 and 15 of a 28-day cycle. The ORR was 55%, and CR occurred in 27% of the patients. Grade 3 or higher adverse events were seen in 65% of patients.<sup>64</sup> These results suggest that romidepsin + duvelisib could be a potential therapeutic strategy to be evaluated in larger studies.

### Panobinostat and Bortezomib

Another experimental combination was the association of HDACi and proteasome inhibitors based on the activity and the efficacy of these two classes in PTCLs. Tan et al reported the results of a phase II trial evaluating the combination of panobinostat and bortezomib. Patients received 20 mg oral panobinostat three times a week and 1.3 mg/m<sup>2</sup> intravenous bortezomib two times a week, both for 2 of 3 weeks for up to eight cycles. The ORR was 43% (10 of 23 patients), and the CR rate was 22% (5 of 23 patients). However, the PFS was very limited, which can be attributed to the short response time in highly aggressive disease.<sup>65</sup>

## Future Directions with Selected Innovative Chemo-Free Drugs for PCTLs

- (a) New epigenetic drugs. As described above, PTCLs are characterized by the frequency of alterations in histone methylation and acetylation genes. New drugs that target the epigenome, proliferative signaling pathways, and the tumor microenvironment are in clinical development. EZH2, encoding for histone-lysine N-methyltransferase enzyme, is a therapeutic target. DS-3201b, an EZH1/2 inhibitor, has shown *in vitro* activity against lymphoma cell lines.<sup>66</sup> An ongoing international multicenter phase I trial is evaluating DS-3201b in patients with lymphomas including PTCLs (NCT02732275). Preliminary results published as abstract and presented at ASH 2017 showed an encouraging ORR of 80% in patients with R/R TCLs. However, this study suffered from an extremely low patient number (1 CR and 3 PR of 5 patients).<sup>67</sup> AG-221, an IDH2 inhibitor approved in patients with AML, has been studied in patients with advanced solid tumors harboring IDH2 mutation including R/R AITL. The results of this phase I/II trial have not been published yet, more than 3 years after study completion (NCT02273739).
- (b) JAK inhibitors. A phase II trial is evaluating the efficacy of ruxolitinib, a JAK1/2 inhibitor in R/R lymphomas including PTCLs (NCT01431209). Preliminary results showed that ruxolitinib can produce response in patients with R/R PTCL.<sup>68</sup> Cerdulatinib, an oral inhibitor of the spleen-associated tyrosine kinase (SYK), JAK1, and JAK3, has also shown interesting activity in PTCL. In a phase II study involving 45 patients with PTCL and 25 with cutaneous T cell lymphoma, the ORR was 35%.<sup>69</sup> These early studies demonstrate that targeting the JAK/STAT pathway can be clinically beneficial for those patients.
- (c) Apoptotic inhibitors. Apoptosis or programmed cell death is often altered in cancer cells, and can be prevented by overexpression of anti-apoptotic proteins, such as BCL2, MCL1, XIAP, and cIAP.<sup>70</sup> These anti-apoptotic proteins are key regulators of pro-survival signaling pathways, and their deregulation through overexpression or loss of endogenous antagonists occurs in various cancer types such as T-cell lymphoma.<sup>70</sup> Venetoclax, a BCL-2 inhibitor that has been approved for the treatment of chronic lymphocytic leukemia and AML, is now being investigated in FIL\_VERT study. It is an open-label, multicenter phase II clinical trial enrolling patients with BCL-2-positive TCL including PTCL-NOS and AITL (NCT03552692). ASTX660 is an oral novel non-peptidomimetic small-molecule antagonist of cellular/X-linked inhibitors of apoptosis proteins (cIAP1/2 and XIAP). It is currently being evaluated in a first-in-human Phase 1–2 study in patients with lymphoma (NCT02503423).
- (d) Anti-CD38 monoclonal antibodies. ENKTL is characterized by the high expression of CD38.<sup>71</sup> Daratumumab, a monoclonal anti-CD38 antibody approved for the treatment of multiple myeloma, showed an ORR of 25% when used as monotherapy in patients with R/R ENKTL in a phase II trial.<sup>72</sup> A multicenter phase II trial will evaluate the association of daratumumab with gemcitabine, dexamethasone, and cisplatin in patients with R/R CD38+ PTCL-NOS, AITL, and other nodal lymphomas of Tfh cell origin (NCT04251065).
- (e) Bi-specific CD30 based immunotherapy. T cells and NK cells are immunologic effector cells with the potential to fight cancer via tumor cell lysis. Bispecific antibodies targeting CD30 positive tumor cells were investigated in phase 1 clinical studies in the context

of Hodgkin lymphoma: an anti-CD30×CD16 and an anti-CD30×CD64 antibody.<sup>73,74</sup> AFM13 is a first-in-class tetravalent bispecific antibody that specifically binds to CD30 on tumor cells and to CD16a on NK cells. It is now entering a registration directed phase II (REDIRECT) trial in patients R/R CD30+ T-cell lymphoma or transformed mycosis fungoides (NCT04101331).

- (f) Immune checkpoint inhibitors (other than anti-PD1). Another approach to treat patients with PTCLs is targeting tumor microenvironment using ICI. Among the checkpoints other than PD-1, ICOS is widely expressed in some T-cell lymphoma, and its targeting promotes potent tumor cell killing.<sup>75</sup> MEDI-570 is a monoclonal antibody that targets ICOS, a member of the CD28/CTLA-4 family. An ongoing phase I trial is evaluating MEDI-570 for the treatment of patients R/R PTCL follicular variant and AITL (NCT02520791).
- (g) Cell therapy for T-cell lymphoma. Chimeric antigen receptor T (CAR-T) cell based therapy is another innovative technique which is being investigated in patients with R/R PTCLs. In an open-label phase I trial, CD30-targeting CAR-T cell was associated with an ORR of 39% (7/18 patients with partial response) in patients with R/R Hodgkin Lymphoma (HL).<sup>76</sup> Ramos et al reported the results of another phase I trial evaluating CD30-specific CAR-T cell in 9 patients with R/R HL (7 patients) or ALCL (2 patients). One patient with ALK+ ALCL presented CR lasting for 9 months; the other patient with cutaneous ALK- ALCL showed no response to CAR-T cell.<sup>77</sup> A single-center, open-label phase I trial is now evaluating CD30-specific CAR-T cell therapy in patients with R/R PTCLs and HL (NCT04008394). Furthermore, a phase II trial is now studying another CD30-specific CAR-T cell in patients with R/R CD30+ PTCLs (NCT04083495). Several other CAR-T cells are being evaluated in clinical trials targeting CD7, CD5 or CD4. The most encouraging approach is targeting TCR in order to eradicate malignant T cell clones. The efficacy and specificity of CAR-T cells that target TCR  $\beta$ -chain constant domain (TRBC1) in vivo and in vitro have been reported by Maciocia et al.<sup>78</sup>

## Conclusion

The management of patients with PTCLs remains challenging, with slow progress being made in the field, and only

few drugs are currently approved. This is mainly due to the rarity of the disease and its aggressiveness, much complicating trial recruitment. Furthermore, given the various biological and molecular patterns, and the increasingly precise dissection of the molecular and immunological abnormalities of the disease, international collaboration seems crucial, and pan T-cell lymphomas trials are more and more regarded as a failed strategy. Innovative drugs targeting epigenetic mechanisms, immune checkpoint modulations, CD30 and TCR abnormalities with cellular therapies portend much hope to improve the outcomes of these patients in the upcoming years.

## Disclosure

Dr Jean-Marie Michot reports being a principal/sub-investigator of clinical trials for Abbvie, Amgen, Astex, AstraZeneca, Debiopharm, Lilly, Roche, and Xencor, during the conduct of the study. Dr Vincent Ribrag reports non-financial support from Astex, Abbvie, BMS, Sanofi, and Servier, grants and non-financial support from Argenx, personal fees from Gilead, Roche, Incyte, and Nanostring, and personal fees and non-financial support from MSD and AZ, during the conduct of the study. The authors report no other potential conflicts of interest for this work.

Journal of Experimental Pharmacology

Dovepress

Publish your work in this journal

The Journal of Experimental Pharmacology is an international, peer-reviewed, open access journal publishing original research, reports, reviews and commentaries on all areas of laboratory and experimental pharmacology. The manuscript management system is completely

online and includes a very quick and fair peer-review system. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/journal-of-experimental-pharmacology-journal>
