## Abstract

**Objective:** The delivery of healthcare at home has expanded to intravenous infusions of monoclonal antibodies. A recently developed model of care for home infusions of natalizumab for people with relapsing-remitting multiple sclerosis was evaluated. This pilot study of home infusions of natalizumab and usual care (attendance in a hospital out-patients' clinic) compared safety, feasibility, patient satisfaction, effectiveness and costs. **Methods:** In this randomised AB/BA crossover trial, 37 adults were randomised to usual care ( $n = 19$ ) or home infusions ( $n = 18$ ). After three infusions, patients crossed over to the alternate treatment for another three infusions. Patient safety outcomes and adherence, satisfaction, quality of life, disability and costs were compared. **Results:** No adverse events were recorded from 207 infusions from 35 patients across both home and clinic infusions. There was no difference in adherence ( $p = 0.71$ ) and infection rates ( $p = 0.84$ ) between home and clinic settings. Satisfaction with "convenience" of home infusions was significantly greater ( $p = 0.008$ ) but there were no differences in quality of life measures. Excluding pharmacy, costs were A\$74 lower per infusion at home, including A\$16 of patients' out-of-pocket costs. **Interpretation:** There were no differences in safety and effectiveness between clinic and home infusions of natalizumab. The home infusions were shown to be feasible, more convenient and less expensive than usual care. Larger scale studies are required to verify these preliminary findings, particularly around safety and management of hypersensitivity adverse events in the home setting and for equivalence of clinical outcomes.

## Introduction

Natalizumab (Tysabri<sup>TM</sup>, Biogen Inc, Cambridge, Massachusetts) is routinely delivered as a 1-h intravenous infusion under physician supervision in hospital clinics, day units and free-standing infusion centres for people with relapsing-remitting multiple sclerosis (MS).<sup>1</sup> Natalizumab therapy is generally well tolerated by patients although known adverse drug events include hypersensitivity (e.g. anaphylaxis, urticaria), infections (e.g. urinary tract infections) and milder non-specific infusion-related reactions such as fatigue, headache and rash.<sup>2,3</sup> Acute

hypersensitivity reactions occur in 3%–4% of patients, mostly during the first or second infusion.<sup>4</sup>

In the longer term, the main adverse event of concern is opportunistic infection by the John Cunningham Virus (JCV), increasing the risk of progressive multifocal leukoencephalopathy (PML).<sup>5</sup> The presence of anti-JCV antibodies, natalizumab treatment for more than 2 years and prior immunosuppressant use is associated with an increased risk of PML.<sup>6</sup> Routine monitoring of the anti-JCV antibody index and magnetic resonance imaging screening may be used to inform a risk-stratified approach to natalizumab treatment and PML, especially

for immunosuppressant-naïve patients.<sup>7</sup> Aside from PML, the longer term safety of natalizumab is consistent with shorter use safety profiles.<sup>8,9</sup>

There is a worldwide trend to delivering healthcare in the community rather than hospital, which is partly driven by increased demand for hospital services and benefits to patients.<sup>10,11</sup> Such benefits include reduced incidence of nosocomial infection; greater convenience, comfort, choice and flexibility and patient-centred care; and reduced stress and out-of-pocket expenses.<sup>12–15</sup> Infusion therapy at home began in the 1970s with parenteral nutrition and intravenous immunoglobulin, and has more recently expanded into other diseases and treatments, including cancer and cellulitis.<sup>16–18</sup> A systematic review of home infusion therapy concluded that home infusions were safe and clinically effective, resulted in significantly lower costs and were overwhelmingly preferred by patients because of increased physical and mental wellbeing and decreased disruption of family and personal responsibilities.<sup>19</sup> Although uptake of home infusions of monoclonal antibodies has lagged other forms of treatment such as antibiotic therapy,<sup>19</sup> home infusions of infliximab have been demonstrated to be safe and cost-effective for children and adults with Crohn's disease<sup>20,21</sup> and, more recently, natalizumab has been delivered by infusion at home for people with MS.<sup>22</sup>

A new model of care<sup>23</sup> of home infusions of natalizumab must be demonstrably safe, feasible to deliver, acceptable for patients and healthcare staff, effective in treating symptoms and cost-effective. As a companion piece to qualitative studies investigating acceptability<sup>24</sup> (Juaton M, Cusack L, Schultz T. Healthcare workers' experiences of transitioning natalizumab infusions from hospital services to an in-home setting: A qualitative study. under review), this study is a pilot study of home infusions of natalizumab and usual care (attendance in a hospital out-patients' clinic) to compare safety, feasibility, patient satisfaction, effectiveness and costs.

## Methods

### Trial design

The study design was an AB/BA randomised crossover trial, helping to maximise power from a pilot study.<sup>25</sup> After recruitment, participants were randomised to an AB (i.e. commencing in the clinic) or BA (commencing at home) trial group; after three infusions in treatment period 1 patients crossed over to the alternate model of care for another three infusions in treatment period 2. The washout period between treatment periods was 4 weeks, which is the standard period between infusions required to maintain therapeutic levels of natalizumab.<sup>6</sup>

### Participant recruitment and randomisation

Commencing in November 2016, patients were recruited from the Royal Adelaide Hospital Ambulatory Care Day Unit during their usual infusions. Recruitment continued until January 2017 using the following inclusion criteria:

- ability to understand the purpose and risks of the study and provide signed and dated informed consent and authorisation to use protected health information,
- adult MS patients ( $\geq 18$  years) being prescribed natalizumab,
- a minimum of six prior natalizumab infusions in an infusion service unit and assessed as safe for the home infusion program by the prescribing Neurologist and
- JCV negative.

Patients not meeting each inclusion criteria, or unable or unwilling to provide informed consent, or living outside of metropolitan Adelaide were excluded.

A 1:1 allocation block randomisation schedule (blocks of 4) was developed using random numbers calculated from MS-Excel by author TS. Participants were randomised by the recruiter (author MJ) contacting author TS immediately after patients consented. We attempted to recruit all eligible patients but a power analysis was not conducted as the main aim of the study was to test safety, acceptability and feasibility.

### Intervention

Prior to the trial commencing, we developed a model of care<sup>23</sup> for delivery of natalizumab infusions in the home by nurses. Prioritising the delivery of patient-centred care safely at home, the model of care was responsive to patient needs and prioritised the nurse–patient therapeutic relationship, while incorporating relevant National Standards and factors such as handing over patients between settings and protection of cold chain using medical couriers.<sup>26</sup> As per usual care protocols in the clinic, before every infusion patients in both the clinic and home infusion settings completed a pre-infusion questionnaire to assess for new symptoms which may suggest PML. In the presence of new PML symptoms, no infusions occur until the patient has been medically reviewed and cleared of concern for PML. This screening is coupled with bi-annual JCV antibody testing and annual magnetic resonance imaging.

### Study outcomes

In addition to demographics and treatment adherence (the proportion of treatments within 3 days of the recommended frequency (either 4-weekly, or 6-weekly for one

patient who had received extended interval dosing for 12 months prior to the study) from the total number of eligible treatments), four types of patient outcomes were measured.

### Patient safety outcomes

Patient safety outcomes included adverse events (AEs) (number, severity, treatment patterns and patient outcomes) and infections (number, type, including whether hospital acquired and treatment) collected by unblinded nurses administering natalizumab after each cycle of treatment. Anaphylaxis, common AEs leading to discontinuation if not previously experienced and general AEs were recorded.

### Patient satisfaction

Patient satisfaction with their previous three infusions was measured at the end of both treatment periods 1 and 2. Unblinded nurses administered the "Treatment Satisfaction Questionnaire for Medication (TSQM)",<sup>27</sup> which has been recently used to measure treatment satisfaction for people with MS.<sup>28</sup> The TSQM consists of 14 items scaled on a 5- to 7-point bipolar scale. Items are combined into four summary scores: effectiveness, side effects, convenience and overall satisfaction; higher scores imply higher levels of satisfaction.

### Quality of life

The 81-item MS Quality of Life Inventory (MSQLI) was administered at the start of treatment period 1 and end of treatment period 2 by unblinded nurses. It consists of 10 individual scales providing a quality of life measure that is both generic and MS-specific.<sup>29</sup> The MSQLI includes the SF-36, one of the most widely used generic health status measures, which includes two summary scales (Physical Components Scale and Mental Components Scale) presented in t-score format, in which a score of 50 is equivalent to the mean for the US population, a score of 60 is one standard deviation (SD) above the mean and a score of 40 is one SD below the mean. Similarly, scores of 70 and 30 are two SDs above and below, respectively, the mean. Other SF-36 subscales are derived from 2 to 10 questionnaire items and are scored out of a total of 100. In all subscales, a higher score is indicative of a better outcome for patients.

The nine other scales of the MSQLI are as follows: MFIS-5, Modified Fatigue Impact Scale; PES, MOS Pain Effects Scale; SSS, Sexual Satisfaction Scale; BLCS, Bladder Control Scale; BWCS, Bowel Control Scale; VIS, Impact of Visual Impairment Scale; PDQ, Perceived Deficits

Questionnaire; MHI, Mental Health Inventory; MSSS, MOS Modified Social Support Survey. Short-form versions of scales were used when available (e.g. use of the 5-item Modified Fatigue Impact Scale).

### Expanded disability status scale

The expanded disability status scale is used to quantify disability in people with multiple sclerosis and monitor changes in the level of disability over time.<sup>30,31</sup> As per the MSQLI, it was administered at the start of treatment period 1 and end of treatment period 2 by unblinded author KW, who had undergone training, and measured EDSS under the supervision of author JR.

### Costs

The costs to deliver infusions (including direct costs such as nursing and consumables, and indirect costs such as overheads and facility management) were derived from the clinic's Casemix Clinical Costing System and the home nursing provider's own costings, which also included additional costs such as medical couriers and professional indemnity insurance. Additional financial (including travel, parking) and human resources (time, being accompanied to infusions, use of carers), and healthcare utilisation by patients (visiting a general practitioner or the emergency department, being admitted to hospital or seeing a carer) between infusions were recorded by nurses surveying patients after each infusion.

### Analyses

Descriptive statistics for continuous and categorical demographic variables were calculated, and chi-square and *t*-tests (for normally distributed data) were used for simple inferential tests. For healthcare utilisation, each participant was categorised on a 2 × 2 matrix of utilisation at the clinic and home during their three infusions; differences between matched pairs were tested using McNemar's test.<sup>32</sup> For multivariate analysis, assumptions of a linear regression model were tested by assessing scatter plots and histograms for normality of residuals and random scatter of variance. Linear mixed-effects models were performed for SF-36 and MSQLI variables versus the interaction of group (AB and BA) and treatment periods (1 and 2), controlling for repeated measurements over time. When assumptions of a linear model were not met (e.g. TSQM, some MSQLI subscales), ordinal logistic generalised estimating equation (GEE) models were performed versus the interaction of intervention group (AB and BA) and treatment periods (1 and 2), controlling for repeated measurements over time.

The analyses were conducted using SAS by a statistician blinded to the allocation of treatment.

## Ethical considerations

The study was approved by the Royal Adelaide Hospital Human Research Ethics Committee (HREC/16/RAH/192). Prior to performing any study-related activities, written informed consent was obtained from the participant. Prior to obtaining informed consent, all potential participants were provided with an information sheet relevant to the subject's participation and presented in an easy to understand form. The study protocol was registered with the Australian New Zealand Clinical Trials Registry (ANZCTR CT-2016-CTN-02067-1).

## Results

### Patient characteristics and adherence

Of the 37 randomised participants, 35 received the allocated intervention (Fig. 1). There were no demographic differences between the groups at treatment period 1 (Table 1). Most participants were female, were employed or conducting home duties, and had not experienced a relapse since being on natalizumab over a mean of  $4.7 \pm 2.4$  (SD) years. The mean age of participants was  $39.6 \pm 13.7$  years and age at diagnosis was  $31.1 \pm 10.0$  years. Participants had attended the clinic for most (4.5 years) of the 4.7 years of their natalizumab use (Table 1). All were diagnosed as relapsing-remitting MS.

In terms of treatment adherence, of the 207 infusions across interventions A and B, 170 (82.1%) were delivered within 3 days of the recommended date (i.e. for 34 of 35 patients within 31 days of the previous infusion, for one patient on extended interval dosing within 45 days). There was no difference between clinic (A) and home (B) in the treatment adherence rate (84/103, 81.6% at clinic, 86/104, 82.7% at home) ( $\chi^2 = 0.0$ ,  $p = 1.0$ ).

### Patient safety outcomes

Nil AEs were reported during either the home infusion or usual clinic-based care. Infections were reported for 11 patients on a total of 18 occasions. There was no difference in the number of infections during home care (8) compared to clinic (10) ( $\chi^2 = 0.04$ ,  $p = 0.84$ ). Respiratory infection was the most commonly reported infection overall (six in the clinic compared to one at home). Urinary tract infection was the most commonly reported infection at home ( $n = 3$ ) compared to the clinic ( $n = 2$ ); all of these cases were specific to one patient, persistent and related to self-catheterisation. Two skin infections

( $n = 2$ ) were reported during home care and one was reported during clinic care.

### Patient satisfaction

Satisfaction measures improved from treatment period 1 to 2 for group AB, which started at the clinic, and tended to decrease between treatment periods in group BA, which started at home (Fig. 2A) (Table S1).

Table 2 presents odds of a poor outcome (i.e. decreased satisfaction) in group AB divided by odds of a poor outcome in BA to give an Odds Ratio, 95% confidence interval and interaction  $p$  value. There was a statistically significant interaction for "Convenience" (interaction  $p$  value = 0.001). For Group AB, the odds of a low (poor) convenience score at treatment period 2 by treatment period 1 are 94% less than the odds of low (poor) convenience score at treatment period 2 by treatment period 1 for Group BA (Odds Ratio = 0.06, 95% CI 0.01, 0.31). In other words, participants who recently had home infusions were significantly more satisfied with the convenience of their treatment than those who most recently had infusions in the clinic. The direction of odds ratios ( $<1$ ) for other satisfaction measures showed positive, though not statistically significant, trends in favour of home infusions (Table 2).

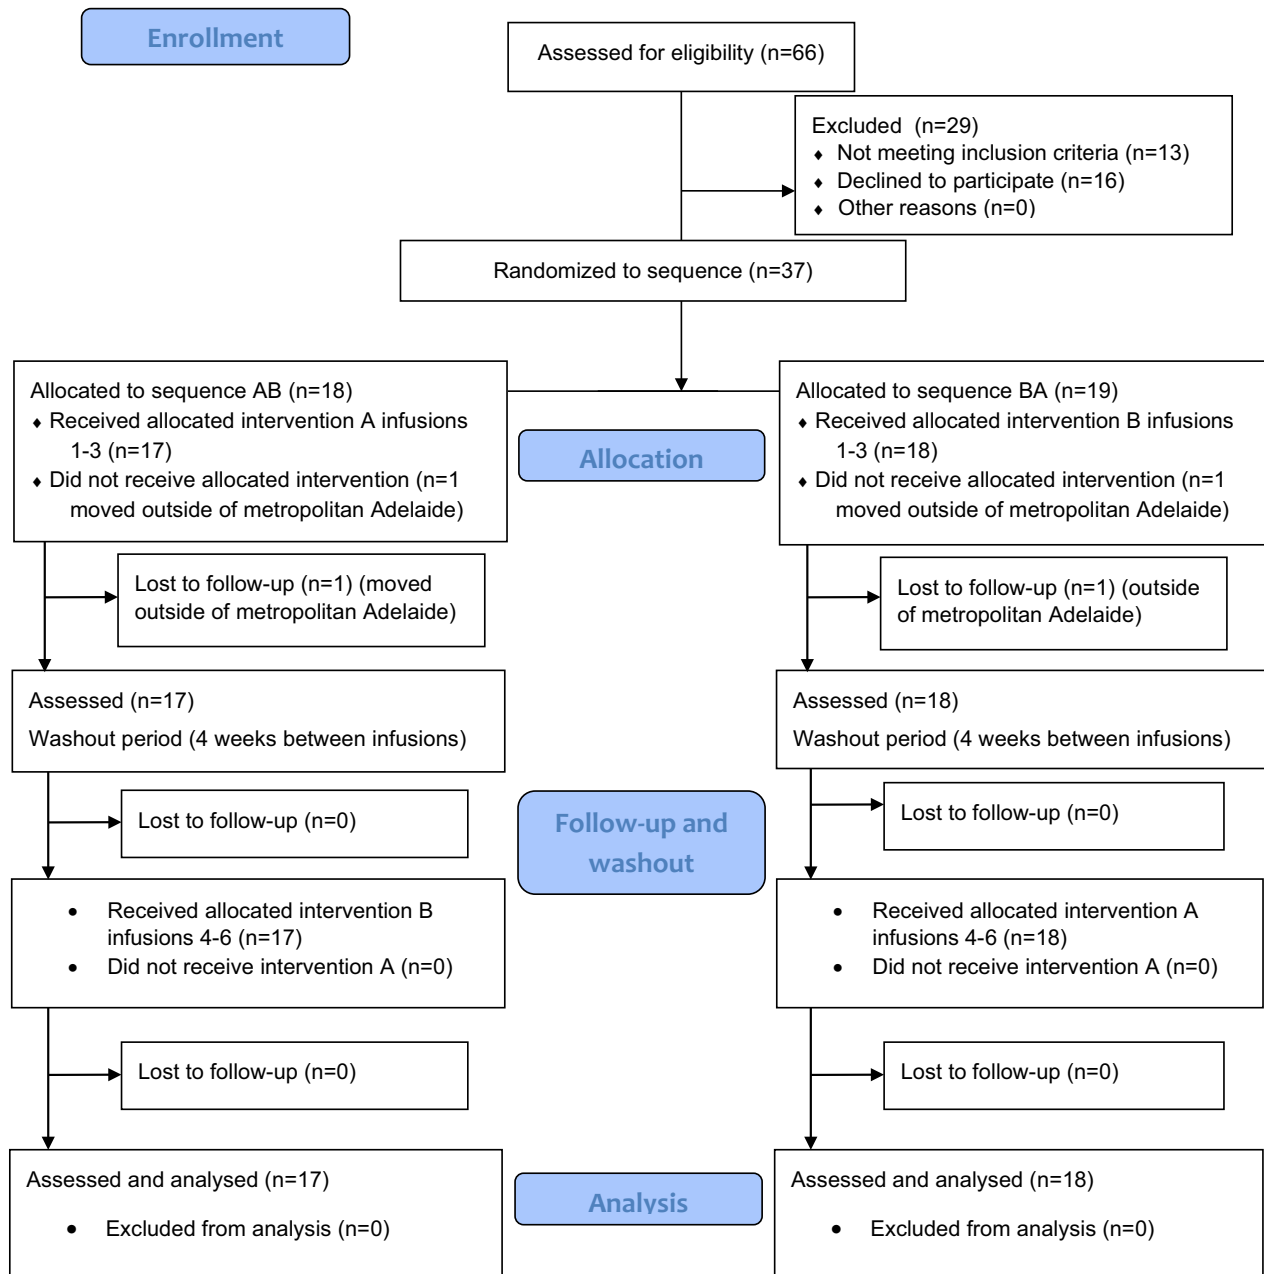

### Quality of life

#### Health status questionnaire (SF-36)

At the start of treatment period 1, groups AB and BA were about 1 SD below the mean score (for the US population) for Physical Components, and  $\sim 1$ –0.5 SD below the mean score for Mental Components (Fig. 2B and Table S2). There was a small increase in virtually all SF-36 subscales between treatment periods 1 and 2 for both groups AB and BA, suggesting that all aspects of the general health of participants slightly improved during the trial (Fig. 2B and Table S2A). Linear mixed-effects models for SF-36 and subscales showed no statistically significant interactions between group and treatment period for any of the SF-36 outcomes (Table 2).

#### Other MSQLI scales

Results for nine MSQLI scales as presented in Figure 3 and Table S3 show similar patterns for both groups. Most of the scales tended to decrease slightly between the treatment periods indicating fewer problems. The opposite patterns in two scales (MHI and MSSS) indicate a slight improvement in these outcomes. Regardless, there were no statistically significant interactions between group and treatment period for any of these MSQLI outcomes (Table 2).

**Figure 1.** CONSORT (2010) Flow diagram of participants in the crossover trial (A-Infusion clinic, B-Home infusions; CONSORT=Consolidated Standards of Reporting Trials).

### Expanded disability status scale

Expanded disability status scale (EDSS) scores were measured on all participants at the start of treatment period 1, but due to an unexpected absence of qualified staff and the transition to a new hospital site, only 14 measurements were made in treatment period 2 (Table 3). Under the EDSS criteria, the mean score of 3.0 at treatment period 1 is described as “Moderate disability in one

functional system, or mild disability in three or four functional systems. No impairment to walking”.<sup>31</sup> Due to the low numbers of patients in each group, we did not conduct further statistical analysis on this data.

### Costs

Excluding pharmacy costs, the mean costs for an infusion at the clinic (comprising, e.g. nursing, consumables ward

**Figure 2.** Mean ± 1 SD for AB (*n* = 17) and BA (*n* = 18) for (A) four Treatment Satisfaction Questionnaire for Medication (TSQM) domains (transformed scores, range from 0 to 100) and (B) eleven subscales of the SF-36.

costs and non-clinical) was A\$538 ± 74 and the cost to deliver a home infusion (comprising, e.g. nursing time and travel costs, medical courier and insurance) was \$58 lower (A\$480). The mean “out of pocket” costs to patients were \$16.70 ± 15.70 at the clinic and \$0.30 ± 1.80 at home. The mean time spent per infusion was 146 ± 15.70 min in the clinic and 53.9 ± 14.6 min at home. In terms of human resources and healthcare utilisation between infusions, across all three infusions in clinic and home settings, most participants were accompanied to the infusion, however, this occurred significantly more often at home than in the clinic (McNemar test, *p* = 0.037) (Table 4). There were no other differences between clinic and home (Table 4).

### Discussion

A new model of care for delivering natalizumab infusions in patient’s homes was safe for patients. Indeed, no AEs were reported in any of the 207 infusions conducted in either the clinic or home settings, replicating earlier

findings for a similar number of patients over a longer time frame and a total of 494 infusions.<sup>22</sup> Although 1%–2% of natalizumab infusions involve an AE,<sup>6</sup> patients in this study had on average 5 years’ experience with natalizumab and were excluded if they had fewer than six prior infusions when AEs are more likely.<sup>4</sup> Additionally, those more likely to experience an AE (based on past experience) may have been less likely to consent. The small size of these two studies of home infusions of natalizumab suggests that a larger study is required to test the safety and home AE management strategies in the longer term, including ongoing monitoring for PML.

We anticipated that home infusions may result in a lower number of infections from reduced exposure of potentially immunocompromised patients to nosocomial infection in the clinic. We found no obvious differences between home and clinic infection rates, and an overall infection rate of 18/207 (8.7%). Although low numbers and aetiological differences between infection types may have impacted these findings, there is no comparative infection data for other monoclonal antibody home

**Table 2.** Ordinal logistic GEE model results (failing assumptions of the linear model) for TSQM and three scales of the MSQLI and linear mixed-effects model results of outcome versus Group and Stage interaction, adjusting for clustering on patient ID comparing “difference in A minus difference in B”

infusion programs. It is nevertheless important to note that infection risks for people with MS on disease-modifying therapies are elevated compared to the general population,<sup>33</sup> and infection control in home healthcare is a serious problem, with some 3.5% of patients developing a serious infection during home care.<sup>34</sup>

Feasibility studies can determine whether an intervention is appropriate for further testing, and may focus on issues including acceptability, expansion of a service into a new setting and limited-efficacy testing.<sup>35</sup> Acceptability of home infusions of natalizumab for patients and clinicians has been investigated qualitatively.<sup>24</sup> (Juaton M, Cusack L, Schultz T. Healthcare workers' experiences of transitioning natalizumab infusions from hospital services to an in-home setting: A qualitative study. under review). Additionally, the evidence from this study supports the feasibility of home infusions of natalizumab, albeit with limitations due to the short-time frame of three home infusions, limited statistical power from the small number of participants and potential for bias in the unblinded measurement of outcomes such as TSQM and loss to follow-up in EDSS measures.

The measurement of similar adherence rates between clinic and home also provides supporting evidence that home care is feasible. However, enhanced flexibility at home did not lead to more timely care for people with MS, a finding that may be explained by the clinic's commitment to ensuring that their patients are adherent to their medication and re-scheduling infusions when required. Indeed, the frequent re-scheduling and last-

minute cancellation of clinic appointments were one of the clinic's reasons for participating in the trial. Although about 18% of infusions are not delivered 4-weekly as prescribed, extended interval dosing to 5- to 7-week intervals does not increase the risk of relapse.<sup>36,37</sup>

The finding of greater "Convenience," as a subscale of Satisfaction, for home infusions is not surprising, given that home care was specifically designed to be patient-centred.<sup>26</sup> This quantitative finding was strongly reflected in the qualitative interviews of 12 patients, in which "convenience for patients and their families" was one of three subthemes under the main theme of "patient-centredness" and contributed significantly to the acceptability of home infusions.<sup>24</sup> Convenience provided patients with autonomy and control over their medical appointments and lifestyle, and freed up time and capacity for family and work.<sup>24</sup> Participants were able to flexibly change the timing of their medical appointment by contacting the infusion nurse; one participant even elected to have an infusion in their workplace.

Infusions at home delivered the same medication at the same dose using the same equipment and the same method of delivery as at the clinic. It was therefore assumed that the home infusions would be equally clinically effective; however, it was important to test this assumption. We found no difference between clinic and home infusions in any of the measures contained in the MSQLI that are commonly used to assess health status for people with MS. Although this study was not powered sufficiently to detect equivalence between the two treatments (which for the main study outcome of AEs would require a sample size of several thousand patients in each group), the similarity in the change from treatment period 1 to 2 in MSQLI, as demonstrated by the linear mixed-effects and GEE models, does offer support that the clinical effectiveness of the medication at home was similar to that in the clinic.

We documented a slight improvement in patients' general health (SF-36) measures between treatment periods 1 to 2 that was consistent between the two study groups.

**Table 4.** Involvement of carers/family members in participants' infusions

	Home – Yes		Home -No		Home - Yes		Home - No		<i>p</i>
	Clinic - Yes		Clinic - Yes		Clinic - No		Clinic - No		
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	
Accompanied by a family member or friend	7	20.0	6	17.1	22	62.9	0	0.0	0.0037
Engaged a carer for a family member	3	8.6	2	5.7	0	0.0	30	85.7	0.50
Visited a GP	4	11.4	4	11.4	2	5.7	25	71.4	0.69
Visited the ED	0	0.0	0	0.0	1	2.9	34	97.1	1.0
Admission to a hospital	0	0.0	1	2.9	0	0.0	34	97.1	1.0
Seen a carer	2	5.7	3	8.6	3	8.6	27	77.1	1.0

The median size of the improvement across all 11 SF-36 subscales was 7.7% in group AB and 6.7% in group BA. The patterns shown in the other scales of the MSQLI are very similar to those demonstrated for the SF-36. Given the heat sensitivity of people with MS, one possible explanation for this is a seasonal effect of improvement in general health from the heat of summer when the trial commenced in February to the coolness of winter (August) when the trial concluded. Alternatively, it may reflect a placebo effect from participation in the trial.

Our estimate is that home infusions are A\$75 less expensive than clinic infusions, with patients' "out-of-pocket" expenses contributing almost a quarter of this amount. Time savings for home infusion patients (~90 min) have not been included in costings but likely contribute to the greater convenience of home infusions, which also includes greater accompaniment by a friend or relative. Although the absolute amounts differ due to methodological differences, these estimates of lower costs at home are supported by a recent Australian study of rapid infliximab infusions, which found that infusions were A\$10.60 less expensive (median \$49.80 vs. \$39.20 per infusion,  $p = 0.20$ ) at home compared to clinic.<sup>38</sup>

### Strengths and limitations

Our study sample was highly experienced MS patients, having been diagnosed 8–9 years previously on average, and having received natalizumab for nearly 5 years, mostly at the clinic. As such, these "expert patients"<sup>39</sup> are well placed to contribute their skills and insights for the improvement of services.

However, this was a pilot study with a small sample size of 35 participants and is therefore underpowered to test for equivalence in any of the main study outcomes. We limited the delivery of home infusions to the Adelaide metropolitan area. Nearly 30% of eligible participants did not consent to participate in the trial, and we were unable (for ethical reasons) to better understand the reasons for this. Outcomes were collected by unblinded nurses delivering infusions.

### Conclusion

This pilot study has demonstrated no differences in safety and effectiveness between clinic and home infusions of natalizumab, and provided strong evidence for feasibility in the latter setting. There was no difference between clinic and home in treatment adherence or quality of life scores. Patients reported that home infusions were more convenient than the clinic, and costs to both the patient and the healthcare system were less at home. Large-scale studies should be conducted to further test these findings,

particularly around the safety and management of hypersensitivity AEs in the home setting and for equivalence of clinical outcomes.

### Acknowledgements

We thank the study participants who agreed to trial the new model of care. We thank the staff of the Ambulatory Care Day Unit at Royal Adelaide Hospital, neurologists at Royal Adelaide Hospital, and staff of Post-Op Care at Home (Pty Ltd) for their participation in the project. The statistical analyses were conducted by Suzanne Edwards, Adelaide Health Technology Assessment, University of Adelaide.

### Conflicts of Interest

Ms Thomas is director of Post-Op Care at Home (Pty Ltd). This organisation was subcontracted to deliver the home care nursing. Therefore, if the outcome of the project is positive and home delivery of natalizumab becomes a new model of care, this could lead to commercial gain for Ms Thomas.

Ms Naidoo is an employee of Biogen, manufacturer of natalizumab. Therefore, if the outcome of the project is positive and home delivery of natalizumab becomes a new model of care, this could lead to commercial gain for Biogen if it leads to more patients receiving natalizumab than would otherwise have been the case. Dr Ravindran received travel support funding for conference attendance from Biogen. All other authors declare that there is no conflict of interest.
