*Keywords:*  Sono/photodynamic treatment Shrimp surimi Microbial community Curcumin

## ABSTRACT

Shrimp surimi is widely acknowledged as a value-added shrimp product due to its delicious taste, rich flavor, and nutrition. However, the refrigerated shrimp surimi is prone to deterioration due to rapid microbial growth during storage. The present study sought to assess the effects of curcumin-mediated sono/photodynamic treatment on bacterial spoilage and shrimp surimi quality stored at 4 ◦C. The total viable count (TVC), microbiota composition, and quality parameters, including the total volatile basic nitrogen (TVB-N), thiobarbituric acid reactive substance (TBARs), and pH were investigated. The results showed that the spoilage bacteria in shrimp surimi rapidly increased with a surge on day 2 during refrigeration storage. The *Psychrobacter* and *Brochothrix* were identified as the Specific Spoilage Organisms (SSOs), which were also positively correlated with TVB-N and TBARs. The results further elucidated that the sono/photodynamic treatment could significantly inhibit the growth of SSOs on the surface and interior of shrimp surimi and delay shrimp surimi quality deterioration. In conclusion, the sono/photodynamic treatment as a non-thermal sterilization method could be a reliable and potential method for inactivating spoilage microorganisms and preserving shrimp surimi quality.

## **1. Introduction**

In recent years, shrimp surimi has extensively attracted the attention of consumers as a value-added food due to its delicious taste, highprotein, and low-fat content. The shrimp surimi consists of shrimp with egg white, starch, and other ingredients, repeatedly grounded to form the creamy appearance and excellent gelling properties [\[1\]](#page-8-0). However, shrimp surimi is vulnerable to microbial contamination and thus becomes spoilage-prone  $[2]$ . So far, frozen storage is the most widely adopted preservation method that enables the long-term storage of shrimp surimi. However, this method significantly deteriorates shrimp quality and taste  $[1]$ . Similarly, refrigerated storage between 0 and 4 ◦C has been widely adopted for short-term shrimp surimi storage, which maintains its flavor, color, texture, and nutrients  $[3]$ , thus making the refrigerated shrimp surimi increasingly popular. For instance, most hot-pot restaurants prefer refrigerated shrimp surimi due to its better taste and popularity among consumers. However, the very short shelf life of refrigerated shrimp surimi increases tremendous

challenges for inventory management, and sometimes results great waste. Besides, this increases the outbreak risk of safety issues. Thus, developing safe and effective approaches for the preservation of refrigerated shrimp surimi is highly necessitated.

Sono/photodynamic treatment (SPDT) is a novel non-thermal sterilization method based on photodynamic treatment (PDT) and sonodynamic therapy (SDT). PDT takes advantages of the bactericidal activity of reactive oxygen species (ROS) generated by light irradiating photosensitizers (PSs). However, the depth of visible light penetration to activate PS is limited, restricting the sterilization of surimi due to the rapid growth of spoilage bacteria in the interior of surimi. SDT shares a similar bactericidal mechanism but replacing light with a low-frequency ultrasonic wave to activate the sensitizers [\[4\].](#page-8-0) Particularly, certain sensitizers could be activated simultaneously by light and ultrasound to produce ROS. Therefore, the sono/photodynamic treatment (SPDT) might combine the advantages of both PDT and SDT as a novel sterilization method. For instance, N. Grevika [\[5\]](#page-8-0) compared the killing efficacy of PDT, SDT, and SPDT against *Staphylococcus aureus* biofilm and

<sup>\*</sup> Corresponding authors at: College of Food Science, Fujian Agriculture and Forestry University, Fuzhou 350002, China. *E-mail addresses:* [jiamiao.hu@fafu.edu.cn](mailto:jiamiao.hu@fafu.edu.cn) (J. Hu), [shaoling.lin@fafu.edu.cn](mailto:shaoling.lin@fafu.edu.cn) (S. Lin).

<sup>1350-4177/© 2021</sup> The Author(s). Published by Elsevier B.V. This is an open access article under the CC BY-NC-ND license [\(http://creativecommons.org/licenses/by-nc-nd/4.0/\)](http://creativecommons.org/licenses/by-nc-nd/4.0/).

<span id="page-1-0"></span>found the highest microbicidal efficacy by SPDT. Similarly, M. Pourhajibagher [\[6\]](#page-8-0) found that the cell viability, metabolic activity, and biofilm growth in *Aggregatibacter actinomycetemcomitans* could be effectively reduced by SPDT using curcumin-decorated nanophytosomes.

Curcumin, as a food additive approved by the European Food Safety Authority, is a yellow pigment isolated from Curcuma longa [7–[10\]](#page-8-0). At present, several studies have reported that curcumin, activated by ultrasonic sound and blue LED light, showed desirable bactericidal activity against a range of bacteria, such as *Staphylococcus aureus* [\[11,12\]](#page-9-0), *Pseudomonas aeruginosa* [\[13\]](#page-9-0), and *Escherichia coli* [\[14,15\]](#page-9-0). Therefore, the antibacterial properties and the changes in shrimp surimi quality during the curcumin-based sono/photodynamic sterilization at 4 ◦C storage

were evaluated in this study based on the adequate penetration activity of ultrasound.

## **2. Materials and methods**

## *2.1. Photo/sonosensitizer, light and ultrasonic sound source*

Curcumin (IUPAC name: (1E,6E)-1,7-Bis(4-hydroxy-3-methoxyphenyl) hepta-1,6-diene-3,5-dione) was purchased from Sigma-Aldrich (St. Louis, MO, USA). A stock solution of curcumin (25 mM) was prepared in ethanol and then diluted in sterile water to obtain the concentrations to be tested. A light-emitting diode (LED) (M425L, Zolix Instruments Co., Ltd, Beijing, China) with peak emission wavelength of

**Fig. 1.** The process of sono/photodynamic treatment for shrimp surimi.

425 nm was used as the light source. Ultrasonic generator XH300B (Beijing Xianghao Tech CO., LTD, Beijing, China) was used to generate ultrasound at 24 KHz.

## *2.2. Sample treatment*

Shrimp surimi was provided by Haixin Foods Co., Ltd, which was composed of shrimp (*>*90% w/w), starch and egg white. The procedure of sono/photodynamic treatment of shrimp surimi samples was illustrated in [Fig. 1](#page-1-0). Briefly, the shrimp surimi samples were mixed with curcumin and then processed with ultrasound and blue lights. For each batch, 25 g shrimp surimi was treated in water (volume 6  $\times$  7.5<sup>2</sup>  $\times \pi$ cm<sup>3</sup>) in a crystallizing dish, and the distance between the ultrasonic probe and the shrimp surimi was 2 cm. Then the shrimp surimi samples were packed in airtight PE bag ( $7 \times 15$  cm, 0.12 mm; JGQUA, Zhejiang, China) and stored at 4℃ for subsequent quality and bacterial analyses.

## *2.3. Orthogonal test*

An orthogonal L9(33) test design was used for the optimization of sono/photodynamic treatment (Table 1). Total viable counts (TVC) of surimi samples upon SPDT treatment at different parameters (curcumin concentration at 200, 400 or 600 nmol/g, ultrasonic power at 300, 600 or 900 W, and sono/photodynamic treatment for 15, 30 or 45 min) were determined.

#### *2.4. Determination of TVC*

TVC was determined according to the method of Li [\[16\].](#page-9-0) Briefly, 10 g of shrimp surimi were homogenized by a food processer (JYL-C012, Joyoung Co., Ltd. China) in 90 mL stroke-physiological saline solution. This initial sample suspension  $(1/10)$  and its subsequent dilutions were prepared in accordance with the procedures described previously, and inoculated on aerobic plate count agar (PCA) (CM0325, Oxoid, Hampshire, UK). After incubation at 30 ◦C for 72 h, the number of colonyforming units (CFU) was counted. Each assay was performed in triplicates.

#### *2.5. 16S microbiome analysis*

Samples for microbiota analysis were collected from shrimp surimi samples on days 0 (immediately after treatment), 1, 3 and 6 during the refrigerated storage. For microbial DNA extraction, E.Z.N.A.® bacteria DNA Kit (Omega Bio-tek, Norcross, GA, U.S.) was used according to the manufacturer protocol. Then, the V3-V4 hypervariable regions of the bacteria 16S rRNA gene were amplified with primers 338F (5'-ACTCCTACGGGAGGCAGCAG-3′ and 806R  $(5'-GGAC-$ TACHVGGGTWTCTAAT-3′ ) by thermocycler PCR system (GeneAmp 9700, ABI, USA). The PCR products was extracted from a 2% agarose gel and further purified using the AxyPrep DNA Gel Extraction Kit (Axygen Biosciences, Union City, CA, USA) and quantified using QuantiFluor™- ST (Promega, USA) according to the manufacturer's protocol. Samples with bright strip between 400 and 450 bp were chose for further analyses. The amplicon library was prepared with a Sample Preparation Kit (Illumina, USA) and sequenced on an Illumina Miseq platform according to standard protocols. Sequences with 97% similarity were defined as an

## **Table 1**

Orthogonal test factors and levels.

Levels	<b>Factors</b>						
	A Curcumin concentration $(nmol/g)$	<b>B</b> Ultrasonic power /W	C Sono/photodynamic treatment time/min				
	200	300	15				
$\overline{2}$	400	600	30				
3	600	900	45				

operational taxonomic unit (OTU) and the representative sequence reads of various OTUs were hierarchically classified into different taxa. Beta diversity was calculated to evaluate species richness and genetic diversity of the microbial community according to Y. Zhang [\[17\]](#page-9-0).

## *2.6. Determination of TVB-N, TBARs, and pH*

TVB-N value was determined according to the method by Jia [\[18\]](#page-9-0)  with minor modification. Briefly, 4 g of shrimp surimi was dispersed in 40 mL distilled water and homogenized by a food processer for 3 min. And then the TVB-N was determined by Kjeldahl Apparatus (KDY9820, Beijing, China). TBARs was determined as described by Deyang Li [19] with minor modification. Briefly, TBARs was calculated by multiplying the absorbance with a coefficient of 7.8 and expressed as mg malondialdehyde (MDA) eq/kg sample. Meanwhile, the pH of the supernatant was measured using a digital pH meter (Mettler Toledo FE20/EL20, Shanghai, China).

## *2.7. Electronic tongue evaluation*

Difference in taste of the shrimp surimi was measured by electronic tongue evaluation system according to the method of Pattarapon [\[20\]](#page-9-0). The shrimp surimi was diluted and stirred with purified water at the ratio of 1:5, and then centrifuged. The supernatant was taken for testing with the taste analysis system TS-5000Z (INSENT, Japan). Reference solution (simulated saliva) was selected as  $30 \text{ mM KCl} + 0.3 \text{ mM tartaric}$ acid. The tasteless points for the taste components were observed to be  $-13$  for sourness,  $-6$  for saltiness, and 0 for others [\[21\]](#page-9-0).

#### *2.8. Statistical analysis*

The differences in TVC, TVB-N, TBARs, and pH among samples were assessed using one-way ANOVA analysis of variance in SPSS 20. Differences were considered significant if  $P < 0.05$ . Data graphs were drawn using GraphPad Prism 8.0 software. Microbiota analysis was performed using Majorbio Cloud Platform ([www.majorbio.com\)](http://www.majorbio.com). The correlation among physicochemical indicators and microbial populations were conducted by Pearson correlation analysis using R software version 3.5.1. and RStudio (R Package, USA), and the significance was verified via Student's *t*-test.

## **3. Results**

## *3.1. The effects of sono/photodynamic treatment on TVC of shrimp surimi*

As depicted in [Fig. 2,](#page-3-0) the TVC of shrimp surimi showed a continuous increase with a surge on day 2 during storage at 4 ◦C. This result revealed that the refrigerated shrimp surimi could only last 2–3 days. A previous study suggested that the edibility and market value of shrimp products are severely jeopardized when their TVC reaches  $10^6$  CFU/g [\[22\]](#page-9-0). The results further demonstrated both PDT and SPDT treatment could significantly decline the increase in TVC, with SPDT showing better bactericidal effects. The TVC of SPDT treated samples were kept below  $10^6$  CFU/g till day 4.

The single-factor analyses suggested that the desirable bactericidal effects (*>*1.3 lg (CFU/mL) decrease) could be achieved when curcumin concentration was above 400 nmol/g, the ultrasonic power *>* 600 W, and the sono/photodynamic treatment time was longer than 30 min.

Based on the single-factor analyses, curcumin concentration, ultrasonic power, and treatment time were further optimized using an orthogonal L9 (33) test design. As summarized in [Table 2](#page-3-0), the results indicated that the minimum TVC (5.89 lg CFU/g) of shrimp surimi was obtained when the curcumin concentration, ultrasonic power, and sono/ photodynamic treatment time were 400 nmol/g, 300 W, 30 min  $(A_2B_1C_2)$ , respectively. It is noteworthy that curcumin concentration plays an essential factor in determining TVC. Thus, this optimized

## *3.2. The effects of sono/photodynamic treatment on microbial community during storage*

High-throughput sequencing analysis based on the Illumina HiSeq2500 platform was performed to assess diversity in microbial communities of shrimp surimi during cold storage and identify the specific spoilage organisms (SSOs) responsible for spoilage of refrigerated shrimp surimi. A total of 1,760,599 sequences (after quality trimming) from the 32 shrimp surimi samples were yielded (raw data can be accessed from NCBI's Sequence Read Archive with SRP324256). The coverage rates of all groups were more than 99%, indicating the reliability of the sequencing data for further study.

β-Diversity visualized by the principal component analysis (PCA) also supported that SPDT could decline the changes in microbial community during the storage [\(Fig. 3](#page-4-0)). The maximum variations in the microbiota of different shrimp surimi samples were 62.6% (PC1) and 29.66% (PC2), suggesting a strong separation by region. As shown in [Fig. 4](#page-5-0)d, the untreated control samples showed significant differences at different time points, while the samples on day 0 and day 1 (SPDT 0 and SPDT 1) were similar in the treatment group. Moreover, the PCA results showed similar microbiota composition in control 1, and SPDT 3 samples, which was consistent with the heat-map generated clustering results.

<span id="page-4-0"></span>

**Fig. 3.** The principal coordinates analysis (PCA) of the microbiota from the control group and the sono/photodynamic treatment group during the refrigerated storage at 4 ◦C.

At the phylum level ([Fig. 4](#page-5-0)a, [Fig. 4](#page-5-0)b), the shrimp surimi bacterial profile of on day 0 (Con 0) was dominated by *Firmicutes* (94.44%). As expected, the SPDT treated shrimp surimi (SPDT 0) had a similar bacterial community profile as the control group (CON 0) on day 0. Notably, *proteobacteria* rapidly increased in the untreated control group, reaching 46.36% on the sixth day, while *proteobacteria* showed no significant changes before the third day in the SPDT treated samples, and *Firmicutes*  remained as the dominant bacteria. However, on the sixth day, *proteobacteria* also dominated the microbial community in SPDT treated samples.

At the genus level [\(Fig. 4c](#page-5-0), [Fig. 4d](#page-5-0)), the shrimp surimi was dominated by *Vagococcus*, *Psychrobacter*, *Macrococcus*, and *Carnobacterium*. In the control group, *Psychrobacter* showed a significant increase from 4.27% on day 0 to 46.15% on day 6, which was similar to the increasing trend of *Brochothrix* from 1.31% to 10.02%. In contrast, *Macrococcus*  decreased from 39.94% on day 0 to 0.31% on day 6. Similarly, *Vagococcus* showed a slight increase in the first 3 days (from 42.81% to 49.79%) but rapidly decreased to 26.67% on day 6. These changes were consistent with the treated group, i.e., *Psychrobacter* became dominant during the storage. Notably, the *Psychrobacter* and *Brochothrix* remained steady up to three days storage, but increased to 52.99% and 11.18%, respectively, on day 6.

A heat-map was generated to analyze and compare the relative abundances and dynamic changes in the microbial community at genus levels (top 20 genera are shown) in all samples at different time points during storage [\(Fig. 5](#page-6-0)). According to the clustering results, the bacterial communities of SPDT-treated samples on day 3 shared the most similarity with the untreated samples on day 1. This result suggested that SPDT treatment could retard the bacterial changes in the first 3–4 days during the refrigerated storage. The changes in the relative abundance of microorganisms elucidated that *Psychrobacter* and *Brochothrix* had a significant increase from 2187 and 670 on day 0 to 22777, and 4948 on day 6, respectively, in the control group.

## *3.3. Changes of quality in shrimp surimi treated with/without SPDT*

TVB-N is one of the most important indicators to assess food

deterioration. Hence, TVB-N was measured to further evaluate the preservative effects of sono/photodynamic treatment on shrimp surimi. As shown in [Fig. 6a](#page-6-0), the sono/photodynamic treatment could effectively inhibit the increase in TVB-N. The TVB-N values of all samples at day 0 were below 6 mg/ 100 g. In the control samples, TVB-N increased continually to over 12.1 mg/ 100 g after 6 days of refrigerated storage, while the samples with sono/photodynamic treatment showed significantly lower TVB-N values (7.28 mg/ 100 g). Similarly, TBARs also showed a time-dependent increase during the 6 days of storage ([Fig. 6b](#page-6-0)), while sono/photodynamic treatment significantly inhibited this upward trend. [Fig. 6](#page-6-0)c depicts the changes in pH of the shrimp surimi stored at 4 ◦C. In the control group, the pH decreased from 8.34 to 7.65. The sono/ photodynamic treatment prevented the shrimp surimi from being sour. On the 4th day of storage, the pH of the treatment group was significantly higher than in the control group (P *<* 0.05) and remained 7.88 for the next two days of storage.

Further, the electronic tongue system was employed to evaluate surimi taste by measuring eight basic senses of taste: sourness, bitterness, astringency, aftertaste-B, aftertaste-A, umami, richness, and saltiness, as presented in [Table 3.](#page-7-0) The electronic tongue showed that the SPDT treated samples stored for 6 days had higher scores in umami, saltiness, aftertaste-A, and bitterness, while the untreated surimi had higher sourness and astringency after 6 days. Additionally, the aftertaste-B showed no significant difference in all the samples. This observation suggested that sono/photodynamic treatment could retain the umami and saltiness in the surimi samples but develop some bitterness and aftertaste A. On the contrary, this treatment also decreased sourness and astringency.

## *3.4. Pearson correlation analysis among TVB-N, TBRAS, taste, and microbial*

As depicted in [Fig. 7,](#page-7-0) the Pearson correlation analysis was employed to analyze the correlation of TBRAS, TVB-N values with the top 10 abundant microbial composition at the genus level as inputs. Notably, TVB-N and TBARs as deteriorative indicators showed a significant positive correlation. Moreover, *Psychrobacter* and *Brochothrix* showed a

<span id="page-5-0"></span>

**Fig. 4.** Relative abundance of the bacteria of shrimp surimi samples during refrigerated based on Illumina-MiSeq sequencing. The statistically significant differences were analyzed using Kruskal-Wallis H test.

significantly positive correlation with TVB-N and TBARs, and a significantly negative correlation with *Micrococcus*, *Streptococcus*, *Enterococcus*, *Lactococcus*, and *Corynebacterium*. Additionally, the results revealed a correlation between bacteria. For instance, *Psychrobacter* and *Brochothrix* might promote each other's growth (positive correlation), while *Psychrobacter* and *Enterococcus* might share a competitive relationship (negative correlation).

Similarly, the Pearson correlation analysis was used to analyze the correlation of electronic tongue taste attributes and microbial composition ([Fig. 8](#page-8-0)). Bitterness was found to have a significantly positive correlation with *Macrococcus*, *Streptococcus,* and *Enterococcus*, and a significantly negative correlation with *Psychrobacter*, *Brochothrix*, and *Carnobacterium*. Astringency was showed a significantly positive correlation with *Vagococcus*, *Macroccoccus*, and *Carnobacterium*, and have a significantly negative correlation with *Psychrobacter* and *Brochothrix*. Afertaste-A showed a significantly positive correlation with *Vagococcus*  while a significantly negative correlation with *Streptococcus*, *Enterococcus*, *Lactococcus*, and *Corynebacterium*. Umami showed a significantly positive correlation with *Micrococcus*, *Streptococcus*, *Enterococcus*, *Lactococcus*, and *Corynebacterium*, and a significantly negative correlation with *Psychrobacter* and *Brochothrix*. Richness showed a significantly positive correlation with *Psychrobacter*, *Corynebacterium*, and *Brochothrix*, and a significantly negative correlation with *Vagococcus*, *Macroccoccu*s, and *Enterococcus*. Saltness showed a significantly positive correlation with *Macroccoccus*, *Enterococcus*, and *Lactococcus* and a significantly negative correlation with *Psychrobacter*, *Corynebacterium*, and *Brochothrix*.

#### **4. Discussion**

Sono/photodynamic, a non-thermal sterilization method, utilizes the activated sono/photosensitizer to inactivate foodborne bacterial pathogens [\[23\]](#page-9-0). Herein, the preservative effects of curcumin-mediated sono/ photodynamic treatment on the quality and microbiota composition of shrimp surimi during refrigerated storage were assessed. The obtained results demonstrated that fresh shrimp surimi rapidly deteriorated during cold storage. The spoilage by rapid microbial growth occurred after 2–3 days of storage at 4 ◦C, limiting the shelf life of shrimp surimi. This finding was consistent with the previous study results reported by M. Wang et al., demonstrating that the shelf of *Hypophthalmichthys molitrix* surimi was less than 2 days during cold storage and the TVC increased significantly within 24 h of refrigeration [\[1\].](#page-8-0)

Additionally, the present study results elucidated that curcuminmediated sono/photodynamic treatment inhibited the growth of spoilage bacteria and declined the deterioration of shrimp surimi. According to the CFU measurements, the sono/photodynamic treatment might double the shelf life of shrimp surimi at optimum treatment conditions (curcumin at 400 nmol/g, ultrasonic power at 300 W, and treatment for 30 min). Indeed, Bhavya [\[24\]](#page-9-0) showed that curcumin can be used as the sonosensitizer to sterilize orange juice infected with *Escherichia coli* and *Staphylococcus aureus* and prolong its shelf life. Accumulating studies have also revealed that the sono/photodynamic treatment could effectively inhibit the growth of spoilage bacteria, such as *Staphylococcus aureus* [\[25\]](#page-9-0) and *Aggregatibacter actinomycetemcomitans*  [\[6\],](#page-8-0) which was consistent with our study results. Therefore, sono/

photodynamic could be a potential method to inhibit food-borne microbial growth and used for food preservation.

The changes in the microbial community of shrimp surimi during the refrigerated storage were determined to analyze the antimicrobial effects of curcumin-mediated SPDT in shrimp surimi. *Psychrobacter* and *Brochothrix* were identified as the SSO of shrimp surimi during storage, which was consistent with the previously reported results [\[26\].](#page-9-0) For instance, *Psychrobacter* was found to be the SSO in refrigerated fish [27–[29\]](#page-9-0); while *Brochothrix*, a Gram-positive bacterium, was considered as the predominant spoilage microbiota of shrimp and fish [\[30\]](#page-9-0). Zhang et al. [\[31\]](#page-9-0) isolated P*sychrobacter glacincola 38*–*1*, *Brochothrix thermosphacta 38*–*2*, and *Pseudomonas fragi 38*–*8* from fish balls and found that their rapid growth could inhibit the growth of other bacteria during the cold storage.

Moreover, the Pearson correlation also revealed the possible associations between microbial growth and surimi quality deterioration. Both *Psychrobacter* and *Brochothrix* were positively correlated with the increase in TVB-N and TBARs, which was also consistent with the previous reports. TVB-N is usually associated with protein macromolecules degraded by microorganisms [\[32\]](#page-9-0). A previous study has reported that *Psychrobacter* was one of the dominant microbiota of brown shrimp during aerobic storage and associated with volatile compounds formation [\[33\].](#page-9-0) In another study, *Psychrobacter* was reported as one of the dominant microorganisms in the spoiled cuttlefish stored at 2 ◦C and associated with TVB-N accumulation [\[34\]](#page-9-0). Meanwhile, *Brochothrix*, as a facultative anaerobe, was also found to be associated with TVB-N accumulation in fresh chicken burgers [\[35\].](#page-9-0)

Additionally, the electronic tongue system results also supported that the sono/photodynamic could delay the quality deterioration of shrimp surimi during cold storage. Besides, microbial growth plays a vital role in the flavor quality of foods as the changes in the food taste are deeply influenced by the changes in taste substances (including sugar, amino acids, inorganic salts and aicds). Our study results also suggested that microorganisms, such as *Psychrobacter* and *Brochothrix* could attribute to the change in flavor by decomposing protein, carbohydrate, fat, and other nutrients of shrimp surimi.

#### **5. Conclusion**

In conclusion, the TVC of refrigerated shrimp surimi rapidly increased and approached  $10^6$  CFU/g by the end of day 2, while the sono/photodynamic effectively inhibited bacterial growth in shrimp surimi. The sono/photodynamic showed some preservative effects on the quality parameters, such as TVB-N and TBARs of shrimp surimi. This

<span id="page-8-0"></span>

**Fig. 8.** The correlation between microorganisms in shrimp surimi samples and taste attributes. The correlation was calculated by Pearson Correlation Analysis. Significant correlations were indicated by \*(P *<* 0.05), \*\*(P *<* 0.01), \*\*\*(P *<* 0.001).

phenomenon might also be associated with the inhibition of shrimp surimi SSOs (*Psychrobacter* and *Brochothrix*) identified by sono/photodynamic. Overall, the sono/photodynamic treatment could be a potential non-thermal sterilization method for preserving shrimp surimi and other refrigerated surimi products.
