Abstract

Summary: The expansion of targeted panel sequencing efforts has created opportunities for large-scale genomic analysis, but tools for copy-number quantification on panel data are lacking. We introduce ASCETS, a method for the efficient quantitation of arm and chromosome-level copy-number changes from targeted sequencing data. Availability and implementation: ASCETS is implemented in R and is freely available to non-commercial users on GitHub:<https://github.com/beroukhim-lab/ascets>, along with detailed documentation.

1 Introduction

Aneuploidy, or copy-number alterations of chromosomes and chromosome arms, is the most frequent somatic alteration in cancer (Taylor et al.[, 2018\)](#page-2-0). Arm-level somatic copy-number alterations (aSCNAs) can drive cancer progression (Liu et al.[, 2016](#page-2-0)), provide information about cancer type [\(The Cancer Genome Atlas Research](#page-2-0) [Network, 2015\)](#page-2-0) and serve as predictive and prognostic biomarkers ([Cairncross](#page-2-0) et al., 2013; [Lamberti](#page-2-0) et al., 2020). Thus, quantitation of aSCNAs is useful in research and clinical decision-making.

Targeted next-generation sequencing (targeted NGS) provides clinicians with rapidly available information about genomic events including copy-number alterations ([Garcia](#page-2-0) et al., 2017). However, there are several challenges in detecting aSCNAs from targeted NGS data. The lower breadth of coverage (BOC; fraction of chromosome arm encompassed by copy-number segments) and significant noise in these data, often obtained from fresh-frozen paraffin embedded (FFPE) samples, often contradict assumptions underlying existing algorithms designed for research-quality whole-exome or genome sequencing data. Perhaps as a result, existing methods for calling copy-number in targeted NGS data do not provide aSCNA calls ([Markham](#page-2-0) et al., 2019; [Shen and Seshan, 2016;](#page-2-0) [Talevich](#page-2-0) et al., [2016\)](#page-2-0) and aSCNAs are not commonly reported or systematically determined. Therefore, novel algorithms are needed.

2 Implementation

We introduce ASCETS (Arm-level Somatic Copy-number Events in Targeted Sequencing), a method for efficient and robust aSCNA detection in targeted sequencing data [\(Fig. 1\)](#page-1-0). ASCETS utilizes segmentation files representing de-noised copy-number calls and

Fig. 1. The ASCETS algorithm workflow

(optionally) raw log₂ copy-ratios (LCRs) for each locus ([Supplementary Methods](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data)). When provided, LCRs are used to determine the noise per segment by separating alternating LCRs within a given segment into two groups and calculating their difference in means. These differences are compiled across all segments and samples to determine a noise threshold representing one standard deviation above the mean. This threshold and its additive inverse are taken as amplification and deletion thresholds, respectively. Optionally, segments of \geq 5 markers with above-threshold noise levels can excluded from further analysis. If LCRs are not supplied, the user may specify the threshold (default: 0.2).

After stratifying amplified and deleted segments, ASCETS computes the BOC of each arm corresponding to each segment class (amplified, deleted or neutral). Arms for which more than a userspecified fraction of territory (default 70%; [Supplementary Table](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [S3\)](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) are encompassed by one class are assigned the respective call (AMP, DEL or NEUTRAL). Arms that do not meet these criteria are not called (NC). Optionally, arms with BOC less than a specified threshold (default: 50%) can be left uncalled (LOWCOV). The supplied arm coordinates can also be replaced with any set of genomic coordinates to call any region of interest, such as cytobands or genes.

3 Results

We evaluated the accuracy of ASCETS calls on two datasets: (i) 9,945 TCGA samples and (ii) 407 glioma samples from the Dana-Farber OncoPanel assay ([Garcia](#page-2-0) et al., 2017). To assess its applicability to publicly available data, we also applied ASCETS to all 34,798 MSK-IMPACT samples in GENIE v7.0 ([The AACR Project](#page-2-0) [GENIE Consortium, 2017;](#page-2-0) [Supplementary Table S1\)](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data). This task completed in 104 min on a consumer-grade laptop with a 3.1 GHz i7 processor and 16 GB of RAM.

We used TCGA data to compare ASCETS calls to 'gold-standard' aSCNA calls from SNP array copy-number data [\(Taylor](#page-2-0) et al., [2018\)](#page-2-0). Because TCGA data have a greater BOC, resulting in a lower level of noise and more accurate segmentation, we modified the TCGA data to simulate the lower BOC found in targeted sequencing data [\(Supplementary Methods](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) and [Fig. S1](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data)). After excluding 50,071 arms with low BOC (<50%) or no call from ASCETS or TCGA, 337,594 chromosome arms were retained ([Supplementary Table](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [S2\)](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data). Of the excluded arms, ASCETS alone called 18,857 arms; TCGA alone called 6,160 and 25,244 were no-called in either dataset.

ASCETS and TCGA calls were 90.3% concordant (Kappa statistic 0.768, P-value [accuracy > no information rate $(NIR)] < 2.2e-16$). The positive predictive value (PPV) and negative

predictive value (NPV), respectively, were 83.5% and 97.0% for amplifications and 95.8% and 94.6% for deletions ([Supplementary](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [Table S4](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data)). Discordant aSCNA calls tended to occur in samples with higher subclonal genome fractions (med. 0.19 versus 0.06, Wilcoxon $P < 2.2e-16$, [Supplementary Fig. S2a](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data)), lower tumor purity (med. 0.50 versus 0.66, Wilcoxon $P < 2.2e-16$, [Supplementary](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [Fig. S2b](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data); Carter et al.[, 2012\)](#page-2-0) and lower magnitude average LCRs (med. 0.17 versus 0.37, Wilcoxon $P < 2.2e-16$, [Supplementary Fig.](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [S2c](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data)), but exhibited no differences in median alteration fraction (med. 0.96 versus 0.96, Wilcoxon $P < 2.2e-16$, [Supplementary Fig.](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [S2d\)](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data). Similar concordance was observed across each chromosome arm and no relationship was seen with arm length ([Supplementary](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [Fig. S2e](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) and f).

We also compared 1p/19q arm-level calls from ASCETS applied to OncoPanel data with results from OncoCopy, a 2 million-probe array comparative genomic hybridization (aCGH) assay ([Ramkissoon](#page-2-0) et al., 2017), across 407 gliomas (Touat et al.[, 2020](#page-2-0)). We called arms with average aCGH LCRs of -0.15 in both 1p and 19q as codeleted. ASCETS exhibited PPV and NPV of 81.6% and
99.7%, respectively (Kappa statistic 0.875, P-value $(Kappa$ statistic 0.875, P-value $[accuracy > NIR] = 2.1e-07$; [Supplementary Fig. S3](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) and [Table S5](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data)). However, 6/7 cases called codeleted by ASCETS but not aCGH were determined to be true positives after expert review of clinical reports [\(Supplementary Table S6\)](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data), corresponding to a PPV of 97.4% and NPV of 99.7%. In addition, 37/38 (97.4%) of cases called codeleted by ASCETS, compared to 80/369 (21.7%) noncodeleted samples, had pathogenic IDH1/2 mutations [\(Touat](#page-2-0) et al., [2020\)](#page-2-0), known to co-occur with 1p/19q codeletion [\(The Cancer](#page-2-0) [Genome Atlas Research Network, 2015\)](#page-2-0).

To assess the effects of the fraction of genomic territory interrogated (FGI) by sequencing and BOC on the performance of ASCETS, we performed a titration analysis ([Supplementary](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [Methods\)](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data). As expected, the performance of ASCETS in calling 1p/19q codeletion increases with FGI and, as a result, BOC. Predictive values were consistently above 90% when at least 0.05% of the bases on each arm were interrogated [\(Supplementary Fig.](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data) [S4a–](https://academic.oup.com/bioinformatics/article-lookup/doi/10.1093/bioinformatics/btaa980#supplementary-data)d).

4 Discussion

aSCNAs cover more of the genome than any other somatic alteration ([Taylor](#page-2-0) et al., 2018), but thus far have received insufficient focus in clinical decision-making as unifying events in cancer. ASCETS allows for the leveraging of large publicly available targeted sequencing datasets like GENIE to identify novel relationships between aSCNAs and clinical or tumoral features. In addition, ASCETS can potentially be employed to call clinically relevant aSCNAs such as 1p/19q codeletion in a research or diagnostic setting. Indeed, ASCETS has already been utilized in recent publications to subclassify brain tumors (Touat et al.[, 2020\)](#page-2-0) and call aSCNAs affecting 9p ([Lamberti](#page-2-0) et al., 2020). We conclude that ASCETS calls are highly concordant with calls from exome and array-based methods, and that ASCETS can be applied broadly to panel NGS datasets. While ASCETS is designed to account for challenges inherent to targeted sequencing data, it can in principle be applied broadly to copy-number data from whole-exome or wholegenome sequencing data. However, like all algorithms for copynumber analysis, ASCETS performs least well in samples and regions with low signal-to-noise ratios, including areas of subclonal or low-level copy-number change, samples with low tumor purity, and regions with low BOC. Users should consider the length of the sequenced regions when applying ASCETS to their own data to ensure they have sufficient BOC to generate accurate calls. Overall, ASCETS is an efficient, accurate method for quantifying aneuploidy and helps address the need for copy-number analysis tools for targeted NGS data.

Funding

This work has been supported by the National Cancer Institute [U24CA210978 to A.D.C. and R.B.], the Fund for Innovation in Cancer Informatics, the Gray Matters Brain Cancer Foundation, Pediatric Brain Tumor Foundation and a generous gift from Alison Poorvu Jaffe.
