HIGHLIGHTS

- An organic solvent-assisted intercalation and collection (OAIC) approach for preparing $Ti_3C_2T_x$ (MXene) was developed.
- The features of OAIC approach are the low requirement for facility, gram-level preparation with remarkable yield and easy control over the dimension of $Ti_3C_2T_x$ flakes.
- The $Ti_3C_2T_x$ flakes prepared by OAIC approach showed the outstanding capacitive and rate performance.

ABSTRACT A good method of synthesizing $Ti_3C_2T_x$ (MXene) is critical for ensuring its success in practical applications, e.g., electromagnetic interference shielding, electrochemical energy storage, catalysis, sensors, and bio-medicine. The main concerns focus on the moderation of the approach, yield, and product quality. Herein, a modified approach, organic solvent-assisted intercalation and collection, was developed to prepare $Ti_3C_2T_x$ flakes. The new approach simultaneously solves all the concerns, featuring a low requirement for facility (centrifugation speed < 4000 rpm in whole process), gram-level preparation with remarkable yield (46.3%), a good electrical conductivity (8672 S cm^{-1}), an outstanding capacitive performance (352 F g^{-1}), and easy control over the dimension of $Ti_3C_2T_x$ flakes ($0.47\text{--}4.60 \mu\text{m}^2$). This approach not only gives a superb example for the synthesis of other MXene materials in laboratory, but sheds new light for the future mass production of $Ti_3C_2T_x$ MXene.

KEYWORDS Two-dimensional materials; MXenes; Controllable sizes; High yield

the yield and/or increase the size of $\text{Ti}_3\text{C}_2\text{T}_x$ flakes [13–17]. However, a method with a perfect trade-off that meets all the aforementioned requirements, *inc.*, good controllability, high yield, low cost, green process, and safety, has to be achieved and remains challenging.

In this work, a modified approach, organic solvent-assisted intercalation and collection (OAIC), is reported to prepare $\text{Ti}_3\text{C}_2\text{T}_x$ flakes in gram-level with enhanced yield (46.3%) and improved quality (area reaches *ca.* $4.60 \mu\text{m}^2$) through a facile approach featuring sonication-free and high-speed centrifugation-free (< 4000 rpm) methods. More importantly, the $\text{Ti}_3\text{C}_2\text{T}_x$ flakes of different sizes can be obtained in different production cycles instead of gradient centrifugation. The $\text{Ti}_3\text{C}_2\text{T}_x$ flakes with median size show the outstanding capacitive and rate performance. To our best knowledge, the OAIC approach that simultaneously meets aforementioned features of a good synthetic method is a novel procedure, which could shed new light on the mass production of other MXene materials in the future.

2 Experimental Section

2.1 Materials

LiF (Sinopharm Chemical Reagent Co., Ltd.), HCl (Sinopharm Chemical Reagent Co., Ltd.), Ti_3AlC_2 (Forsman Scientific, Beijing, Co., Ltd.), DMSO (Aladdin Bio-Chem Technology Co., Ltd.), dichloromethane (DCM, Sinopharm Chemical Reagent Co., Ltd.), and H_2SO_4 (Sinopharm Chemical Reagent Co., Ltd.) are used as purchased without further purification.

2.2 Characterizations

The structure and microtopography of $\text{Ti}_3\text{C}_2\text{T}_x$ were taken with field-emission scanning electron microscopy (FESEM, FEI Apreo HiVac, 5 kV) and transmission electron microscopy (TEM, JEOL JEM-2100F, 200 kV). The crystallographic information was examined by an X-ray diffraction (XRD, Bruker D8 Advance X-ray diffractometer) under filtered Cu-K α radiation (40 kV and 40 mA, $\lambda = 0.15418$ nm), with a step scan of 0.01° , a 2θ range of $5\text{--}65^\circ$, and a step time of 2 s. The element compositions of $\text{Ti}_3\text{C}_2\text{T}_x$ were analyzed by the X-ray photoelectron spectroscopy (XPS, Kratos-AXIS Supra) and energy-dispersive spectroscopy

(EDS, X-Max N 80 T). The atomic force microscope (AFM) image was obtained by Asylum Research AFM. Raman spectroscopy was obtained by a spectrometer model of Renishaw-inVia. The ultraviolet–visible diffuse reflectance spectra (UV–vis DRS) test is obtained by a Hitachi UH4150 spectrophotometer.

2.3 Synthesis of $\text{Ti}_3\text{C}_2\text{T}_x$

The $\text{Ti}_3\text{C}_2\text{T}_x$ flakes synthesized via Route II (the products are denoted as **S-Ti₃C₂T_x**), which by selective etching of Al atoms from Ti_3AlC_2 using HCl/LiF etchant followed as previous report [12]. For OAIC approach, all synthetic procedure of gram-level preparation of $\text{Ti}_3\text{C}_2\text{T}_x$ was recorded in Movie S1 (Supporting Information). The difference between routine preparation (the products are denoted as **O-Ti₃C₂T_x**) described here and gram-level preparation is nothing, but the amount of raw Ti_3AlC_2 and all chemical reagents is enlarged ten-fold. Specifically, for routine preparation, concentrated HCl (35% solution) was added to DI water to prepare the 9 M HCl solution (20 mL total) in a Teflon reactor (Step 1 in Movie S1). 1.6 g LiF was slowly added to this solution and stirred for 10 min with a magnetic Teflon stir bar to dissolve the salt (Step 2). Then, 1 g of Ti_3AlC_2 powders was slowly added into prepared HCl/LiF solution over the course of 10 min to avoid initial overheating of the solution. The reaction mixture was then held at 35°C for 24 h (Step 3). Next, the mixture was washed through at least 4 times of DI water addition, centrifugation (4000 rpm), and decanting, until the supernatant reached to neutral ($\text{pH} \approx 7$) (Step 4). The critical step of OAIC approach is to add multi-layer $\text{Ti}_3\text{C}_2\text{T}_x$ to DMSO at a ratio of 1 g to 20 mL, and stirring at room temperature for 3 h (Step 5), and then, DCM ($V_{\text{DCM}}:V_{\text{DMSO}} = 1:1$) was added to the mixture for completely removing DMSO. The O- $\text{Ti}_3\text{C}_2\text{T}_x$ products were obtained after the centrifugation at speed of 2,000 rpm for at least three times (Step 6). As shown in Figure S1a, the supernatant was nearly clear, indicating little products loss in this step. The clay-like products were obtained by vacuum drying at room temperature for 2 h to remove the residual DCM (Step 7). Then, the DI water was added, vortex shock dispersed, and centrifugated at 3,500 rpm for 30 min to separate the supernatant and sediment (Step 8). The synthesized O- $\text{Ti}_3\text{C}_2\text{T}_x$ flakes dispersed in water homogeneously, which could be stored for one week without obvious precipitation

(Fig. S1b), indicating good dispersion stability. The Tyndall scattering effect could be observed depending on green laser passing through the colloidal solution (Fig. S1b), also indicating the dispersion stability. Taking the supernatant for freeze drying to obtain O-Ti₃C₂T_x products, which named as “O-Ti₃C₂T_x-1” (Step 9). The sediments in step 8 were repeated by step 5 to step 9 for other five cycles to extract the products, which named as “O-Ti₃C₂T_x-2” to “O-Ti₃C₂T_x-6.” The O-Ti₃C₂T_x dispersions of each cycle were shown in step 8 in Movie S1. The final O-Ti₃C₂T_x products were weighted for the calculation of the yield. In the gram-level preparation, the volumes of dispersion in step 8 in each cycle were accurately measured which denoted as V_{dis} . Then, the dispersion of each cycle was extracted for five parts with 5 mL of each part. After freeze drying, the O-Ti₃C₂T_x products of each part were weighted and denoted as m_1 to m_5 . The mass concentration of the dispersion can be calculated by Eq. 1:

$$c = \frac{\bar{m}}{V} \quad (1)$$

where \bar{m} is the average mass of five parts, V is 5 mL. So far, the mass of O-Ti₃C₂T_x products in dispersion of each cycle (denote as m_{dis}) can be calculated by Eq. 2:

$$m_{dis} = cV_{dis} \quad (2)$$

which are summarized in Table S2. The yield of gram-level preparation was calculated by total mass of O-Ti₃C₂T_x products in the dispersion dividing by the mass of Ti₃AlC₂ powders (10 g). Therefore, the O-Ti₃C₂T_x products with controlled sizes can be finally obtained in the form of both solid and aqueous dispersion according to the requirements of sample preparation for different applications.

2.4 Measurement of the Average Area and Lateral Size of Ti₃C₂T_x Flakes

TEM-derived area distributions were determined by measuring the area of 100 flakes using ImageJ analysis software. Histograms were created using 50 bins from 0 to 10 μm², and log-normal distributions were fit. The average value of Ti₃C₂T_x flakes area and SD was extracted from normal distribution fitting. The representative TEM images and Ti₃C₂T_x flakes area log-normal distributions of products from different cycles are shown in Fig. S6a, b. The corresponding lateral sizes of Ti₃C₂T_x flakes were measured by a similar approach, which listed in Fig. S6.

2.5 Preparation of Free-standing Ti₃C₂T_x Films

The free-standing Ti₃C₂T_x films were fabricated through vacuum filtration of the produced Ti₃C₂T_x dispersion from different cycles on a polyvinylidene fluoride (PVDF) membrane (0.45 μm pore size). The Ti₃C₂T_x films were dried in a vacuum system and peeled off from the PVDF membrane. Digital photograph of free-standing O-Ti₃C₂T_x film is shown in Figure S1c. The thickness of the obtained Ti₃C₂T_x films was measured by micrometer caliper.

2.6 Conductivity Measurements

The electrical conductivity of Ti₃C₂T_x films was tested by a four-point probe mapping system (280SI, Four Dimensions Inc., the USA). The Ti₃C₂T_x films were cut into circular shape with diameter of 15 mm. Electronic conductivity σ (S cm⁻¹) was calculated by Eq. 3:

$$\sigma = \frac{1}{R_s \times d} \quad (3)$$

where R_s (Ω sq⁻¹) is the average sheet resistance measured by four-point probe mapping system, and d is the thickness of Ti₃C₂T_x film.

2.7 Electrochemical Measurements

All electrochemical measurements were performed using a CHI660E potentiostat (Chenhua Instruments, Shanghai, China). Three-electrode electrochemical tests were performed in a plastic Swagelok cell (Fig. S1d) where glassy carbon electrodes were used as current collectors for both the working and the counter electrodes [12, 18]. The prepared Ti₃C₂T_x films were punched to the desired size and directly used as the working electrode without addition of any binder. The free-standing overcapactive activated carbon electrode was used as the counter electrode, which was prepared by mixing 95 wt.% of the activated carbon (YP-50, Kuraray, Japan) with 5 wt.% PTFE (60 wt.% dispersion in H₂O, Sigma-Aldrich) in ethanol [18]. The Ag/AgCl electrode in 1 M KCl was used as the reference electrode. Two pieces of Celgard paper (3501) were used as the separator between the working electrode and the

counter electrode. The deaerated 3 M H₂SO₄ was used as the electrolyte (Fig. S1e).

The cyclic voltammetry (CV) was performed at different scan rates ranging from 2 mV s⁻¹ to 10 V s⁻¹ with a working potential window of 0.9 V (-0.7 to 0.2 V vs. Ag/AgCl). Gravimetric capacitances were calculated by integration of the discharge curves in the CV plots using Eq. 4:

$$C = \frac{\int Idt}{m\Delta V} \quad (4)$$

where *C* is the gravimetric capacitances (F g⁻¹), *I* is the discharging current, *m* is the mass of the Ti₃C₂T_x films working electrode, and Δ*V* is the voltage scan window. Galvanostatic charging and discharging (GCD) was performed at the potential window of 0.9 V (-0.7 to 0.2 V vs. Ag/AgCl). The O-Ti₃C₂T_x-3 film electrode was used to measure long-term cyclability at 10 A g⁻¹. The GCD was cycled for 10,000 cycles with a 0.9 V potential window (-0.7 to 0.2 V vs. Ag/AgCl), and gravimetric capacitance in stability test was calculated from the discharging curve. Electrochemical impedance spectroscopy (EIS) was performed at the open circuit potentials of the cells, with a 10 mV amplitude and frequencies ranging from 100 mHz to 100 kHz.

3 Result and Discussion

3.1 Features of the OAIC Approach

Among the various synthetic methods of Ti₃C₂T_x flakes, the traditional 2-step method involves etching the Al atomic layer selectively in the MAX phase by HF, and then obtaining a single layer of Ti₃C₂T_x intercalated by the organic reagent, DMSO, illustrated as Route I in Fig. 1. DMSO can be removed by DI water washing and high-speed centrifugation due to the miscibility of DMSO in water. However, due to the high affinity of DMSO, water and Ti₃C₂T_x flakes, even after centrifugation of 10,000 rpm, large amounts of Ti₃C₂T_x flakes remain dispersed in the supernatant, causing weight loss of the products. In addition, the synthetic method of Route I has high safety risks, and unfavorable hazardous chemicals, which are big hindrances to mass production. Route II is the currently most used method for preparing Ti₃C₂T_x flakes which avoids HF addition. Exfoliations are achieved under strong sonication to obtain the flakes. However, violent mechanical energy during sonication drastically reduces flakes size which is unsatisfied in applications requiring good conductivity and structural integrity [19].

Otherwise, the minimally intensive layer delamination (MILD) approach yields large-size Ti₃C₂T_x flakes, but the vital yield is still unmentioned [3, 20]. Therefore, lessons are learned from Route I and Route II, including several aspects, i.e., avoiding the use of HF, strong sonication, high-speed centrifugation, and weight loss in the decant after centrifugation. The OAIC approach (Route III) is a modified method which combines a part of Route I and Route II, of which features include—but not limited—in the following ways. First, the LiF/HCl etching process is the same as Route II, which meets the moderate etching process. Second, intercalation is reinforced by DMSO, which is similar as most intercalating chemicals in Route I. Third, the well-known “similia similibus solventur” principle is adopted to remove the residual DMSO by DCM because the magnitude of solvent–solvent interactions is much larger than solvent–nano-flakes interactions [21]. In addition, the low boiling point of DCM (39.75 °C at 760 mmHg) is what help DCM to volatilize by vacuum drying. Most significantly, inspired from the fabrication of graphene and Ti₃C₂T_x macro-fibers [22, 23], DCM washing efficiently restrain large weight loss in Route I which is caused by the step of water adding for removing DMSO because of the strong interactions between water and Ti₃C₂T_x flakes. After adding DI water, Ti₃C₂T_x flakes can be brought down from the supernatant by centrifugation (3500 rpm). The sediment can have DMSO added to further intercalate the residues, in which more Ti₃C₂T_x flakes can be extracted after DCM washing and centrifugation in water to enhance the yield. This step can be cycled at least 6 times; each cycle accumulates more Ti₃C₂T_x flakes with increased size in gradients, which is the fourth feature of OAIC approach and the first reported feature among all other approaches. All details of OAIC approach were described and discussed in the experimental section, Movie S1 and supporting information.

3.2 Morphology of Ti₃C₂T_x Flakes Prepared by OAIC

To compare the morphology of Ti₃C₂T_x flakes between Route II and Route III, Route II also carried out products harvesting in many cycles. As shown in the SEM images of the S-Ti₃C₂T_x prepared via Route II (Figs. S2a, b), S-Ti₃C₂T_x flakes are obvious 2D nanomaterials that stick together after drying. The difference in dimension of the S-Ti₃C₂T_x products obtained from the first and sixth cycle

Fig. 2 TEM images of **a** S-Ti₃C₂T_x-1, **b** S-Ti₃C₂T_x-6 flakes through Route II, **c** O-Ti₃C₂T_x-1 and **d** O-Ti₃C₂T_x-6 flakes through Route III. (Inset shows the SAED pattern). **e** AFM image of O-Ti₃C₂T_x flakes with the height profile alongside the red line

is clearly depicted in TEM images (Fig. 2a, b). It should be noted that the quality of S-Ti₃C₂T_x flakes gets worse with the increase in repeat cycles in Route II. The average area of S-Ti₃C₂T_x from different cycles gradually decreases from 0.27 to 0.10 μm², as statistically analyzed in Fig. 3a. TEM images of S-Ti₃C₂T_x obtained from the other cycles are shown in Fig. S3. The SEM morphology of the O-Ti₃C₂T_x-1 flakes (Fig. S2c) and O-Ti₃C₂T_x-6 (Fig. S2d) prepared by the OAIC approach (Route III) is not significantly different with S-Ti₃C₂T_x. However, from TEM images of O-Ti₃C₂T_x-1 (Fig. 2c) and O-Ti₃C₂T_x-6 (Fig. 2d), the O-Ti₃C₂T_x flakes are larger in dimension and have better quality than S-Ti₃C₂T_x. The average areas of O-Ti₃C₂T_x from different cycles

gradually increase from 0.47 to 4.60 μm², statistically analyzed in Fig. 3a. TEM images of other cycles as shown in Fig. S4. Selected-area electron diffraction (SAED) images of O-Ti₃C₂T_x (inset in Fig. 2c, d) indicate the hexagonal crystal structure of O-Ti₃C₂T_x flakes [24], which, together with the measured *d*-spacing of 0.26 nm corresponding to the (01 $\bar{1}$ 0) crystal plane of Ti₃C₂ in the high-resolution HR-TEM image (Fig. S5) indicates the successful preparation of Ti₃C₂T_x [25–27]. Atomic force microscopy (AFM) images of O-Ti₃C₂T_x flakes alongside the thickness profile are shown in Fig. 2e. From the corresponding height cutaway view, the monolayer thickness of O-Ti₃C₂T_x flake is ~1.31 nm, and the double-layer thickness is ~2.41 nm.

Fig. 3 Comparison of **a** average flakes area and **b** yield at different cycles between S- $\text{Ti}_3\text{C}_2\text{T}_x$ and O- $\text{Ti}_3\text{C}_2\text{T}_x$. **c** Conductivity (black) and density (red) of O- $\text{Ti}_3\text{C}_2\text{T}_x$ films versus flakes area. Cycle 1 to Cycle 6 in the figure represents the O- $\text{Ti}_3\text{C}_2\text{T}_x$ products corresponding to different cycles

3.3 Average Areas, Yield and Conductivity of $\text{Ti}_3\text{C}_2\text{T}_x$ Products

The average flakes area (flake-area distribution diagrams in Fig. S6a) and yield of S- $\text{Ti}_3\text{C}_2\text{T}_x$ and O- $\text{Ti}_3\text{C}_2\text{T}_x$ products from different cycles were statistically measured and calculated. Figure 3a shows the average area of S- $\text{Ti}_3\text{C}_2\text{T}_x$ flakes is smaller than O- $\text{Ti}_3\text{C}_2\text{T}_x$ flakes and gradually decreases from 0.27 to 0.10 μm^2 with different 6 cycles. The average area of O- $\text{Ti}_3\text{C}_2\text{T}_x$ flakes is much larger than the former and gradually increases from 0.47 to 4.60 μm^2 . Therefore, as depicted in Route III in Fig. 1, to further intercalate the residues in different cycles by adding DMSO, O- $\text{Ti}_3\text{C}_2\text{T}_x$ flakes with distinctly different dimensions could be obtained, which is the most attractive advantage of the OAIC approach. The yield of the two approaches is summarized in Fig. 3b. The total yield of O- $\text{Ti}_3\text{C}_2\text{T}_x$ products is up to 40.2%, more than 4.6% of the S- $\text{Ti}_3\text{C}_2\text{T}_x$ products. More importantly, the gram-level preparation of O- $\text{Ti}_3\text{C}_2\text{T}_x$ was implemented by enlarging raw

Ti_3AlC_2 materials and the amount of all chemical reagents. The yield of gram-level preparation of O- $\text{Ti}_3\text{C}_2\text{T}_x$ in each cycle is listed in Table S2, and the total yield is up to 46.3%. From the TEM images for O- $\text{Ti}_3\text{C}_2\text{T}_x$ products of gram-level preparation (Fig. S7), the dimensions of flakes also increase with different cycles and maintain good quality. Table 1 compares the lateral size, thickness and yield of O- $\text{Ti}_3\text{C}_2\text{T}_x$ products of this work with other reports [13–17]. It is noteworthy that most reports describe the dimension of $\text{Ti}_3\text{C}_2\text{T}_x$ flakes by lateral size, not the area. Although the area is the more accurate parameter for describing the dimension of $\text{Ti}_3\text{C}_2\text{T}_x$ flakes, the lateral size of O- $\text{Ti}_3\text{C}_2\text{T}_x$ flakes was also measured for comparison (Fig. S6). Therefore, the OAIC approach can prepare $\text{Ti}_3\text{C}_2\text{T}_x$ flakes with large lateral size and simultaneously pays equal attention to the yield.

The electrical conductivity is an important factor for practical applications of MXene. We prepared free-standing $\text{Ti}_3\text{C}_2\text{T}_x$ films (Fig. S1c) through vacuum filtration for electrical conductivity measurement. The density

of additive-free O-Ti₃C₂T_x films possesses densities of 3–4 g cm⁻³ [4]. Sheet resistance maps of Ti₃C₂T_x films (Fig. S6c) show small distribution of different color implies a high degree of Ti₃C₂T_x uniformity. The average sheet resistance values of O-Ti₃C₂T_x-1 to O-Ti₃C₂T_x-6 films listed in Fig. S6. As shown in Fig. 3c, the conductivity of O-Ti₃C₂T_x films increases with the O-Ti₃C₂T_x flake sizes, and up to 8672 S cm⁻¹ of O-Ti₃C₂T_x-6 with 4.06 μm² flakes area. During the preparation of Ti₃C₂T_x through Route II, sonication breaks S-Ti₃C₂T_x flakes into smaller sizes and may introduce defects, which resulting in the lower electrical conductivity [19]. As shown in Figure S6, the conductivity of S-Ti₃C₂T_x film with 0.16 μm² flakes area is 1062 S cm⁻¹ [28], much smaller than O-Ti₃C₂T_x films. Therefore, this OAIC approach provides a means to prepare pure Ti₃C₂T_x films with good electrical conductivity by using large-size flakes.

3.4 Chemical Composition and Structure of Ti₃C₂T_x Flakes

The chemical composition and structure of Ti₃C₂T_x flakes were characterized by EDS, XRD spectrum, Raman, and XPS. Figure 4a, b is the EDS element maps of S-Ti₃C₂T_x and O-Ti₃C₂T_x products, respectively, indicating that the Ti, C, O, and F elements are uniformly distributed on both S-Ti₃C₂T_x and O-Ti₃C₂T_x [24]. From the EDS spectrum of O-Ti₃C₂T_x (Fig. S8), no S element signal was detected, indicating that DMSO could be washed clean by DCM. The XRD spectra of Ti₃AlC₂ powders before and after LiF/HCl etching are shown in Fig. 4c. The (002) diffraction peak of Ti₃AlC₂ shifted to lower angles, and the intense diffraction 2θ peak at ≈39° of Ti₃AlC₂ disappeared, indicating that the Al atoms were selectively etched from the Ti₃AlC₂ structure [29, 30]. In addition, the (002) diffraction peak of delaminated Ti₃C₂T_x flakes shifted from 6.9° of S-Ti₃C₂T_x to 5.9° of O-Ti₃C₂T_x (Fig. S9), which corresponds to the calculated layer spacing increase from 1.28 nm of S-Ti₃C₂T_x to 1.47 nm of O-Ti₃C₂T_x, demonstrating the increase in lattice space of the two products prepared by different approaches. Raman spectra (Fig. 4d) show the as-received Ti₃AlC₂ has similar features compared to a previous report [31], but differs from others [32, 33]. This could be due to the variation in the types of MAX products from different suppliers. Nevertheless, both A_{1g} (270 and 606 cm⁻¹, referred to as the ω₄ and ω₆, respectively) vibrations

of Ti₃AlC₂ shift as a result of etching and Ti₃C₂T_x formation. In the Raman spectra of Ti₃C₂T_x products, the prominent peak ~200 cm⁻¹ is assigned to the out-of-plane (A_{1g}) vibration of Ti, O, and C atoms, and ~720 cm⁻¹ to another A_{1g} vibration of C atoms. The region around 230–470 and 500–650 cm⁻¹ can be assigned to in-plane (E_g) vibrations of surface groups [34]. As in a previous study, the higher intensity of peaks at 200, 387, 611, and 723 cm⁻¹ for O-Ti₃C₂T_x flakes compared with S-Ti₃C₂T_x flakes might be attributed to the differences in flake sizes and surface functional groups between the two approaches [19]. The surficial structural evidence of Ti₃C₂T_x flakes was investigated by XPS. The survey spectrum (Fig. 4e) shows that no S 2p peak (165.5 eV) was detected in O-Ti₃C₂T_x products, which proves that no DMSO residues were left after washing with DCM by the OAIC approach. The atomic ratios of each element from the XPS data of S-Ti₃C₂T_x and O-Ti₃C₂T_x are shown in Table S1, which is consistent with the literature reports [35]. High-resolution XPS spectra provide different surficial structural evidences between S-Ti₃C₂T_x and O-Ti₃C₂T_x. The Ti 2p high-resolution XPS spectrum (Fig. 4f) shows that the signals at 455.8 and 462.1 eV (marked as C-Ti-T_x 2p_{3/2} and C-Ti-T_x 2p_{1/2}, respectively) correspond to Ti-C bonds, and the signals at 459.4 and 465.7 eV (marked as TiO₂ 2p_{3/2} and TiO₂ 2p_{1/2}, respectively) correspond to Ti-O bonds [36]. It is noteworthy that from S-Ti₃C₂T_x to O-Ti₃C₂T_x (as below), there is a distinct increase and decrease in the signal intensity at C-Ti-T_x 2p_{3/2} and TiO₂ 2p_{3/2}, respectively, indicating that there is less oxidation of O-Ti₃C₂T_x than S-Ti₃C₂T_x [20]. In the O 1s high-resolution spectrum (Fig. 4g), the intensity of C-Ti-O_x signal (~530.8 eV) decreases, indicating greater amounts of -OH groups on O-Ti₃C₂T_x than on -O groups. In addition, a significantly decrease in the intensity of TiO_{2-x}F_x signal (≈685.7 eV, Fig. 4h), indicating less -F groups on the surface of O-Ti₃C₂T_x [35]. The absorption spectra between 300 and 1100 nm (UV-Vis) are shown in Figure S10. Both S-Ti₃C₂T_x and O-Ti₃C₂T_x spectra show strong characteristic Ti₃C₂T_x absorbance peaks at ~320 and ~770 nm, respectively [28, 37–39]. After six-time cycles, there was no significant change at the intensity peak of O-Ti₃C₂T_x, indicating no obvious chemical oxidation during the OAIC approach.

3.5 Electrochemical Performance of Ti₃C₂T_x Products

To study the electrochemical performance of the O-Ti₃C₂T_x products by OAIC approach, we vacuum-filtered the

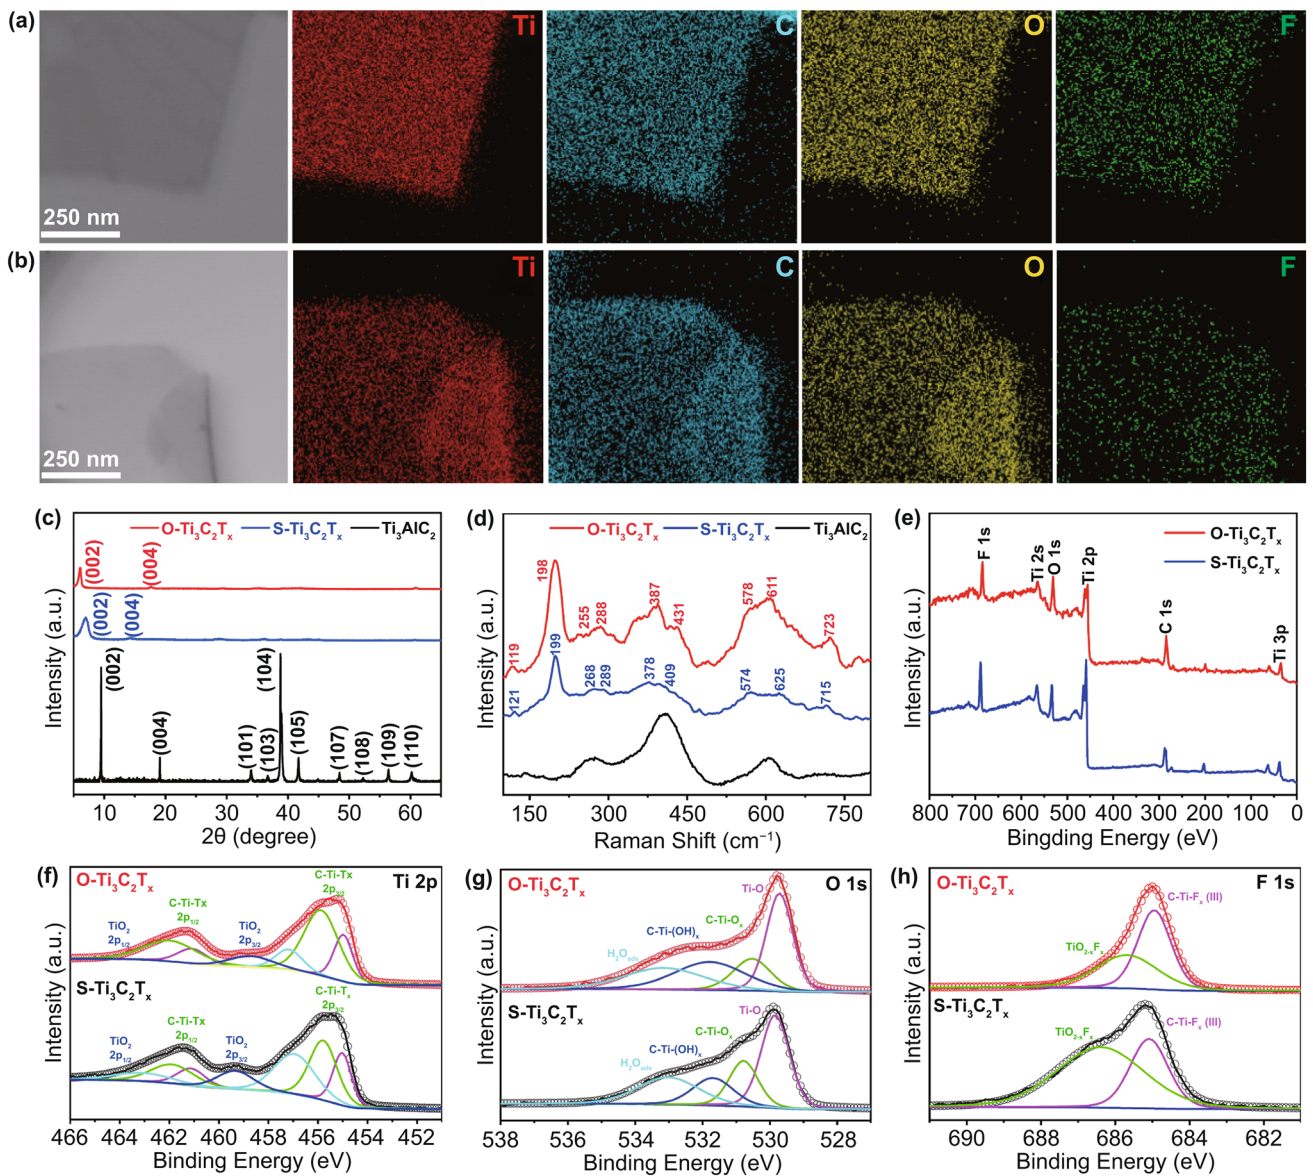

Fig. 4 TEM images of **a** S-Ti₃C₂T_x and **b** O-Ti₃C₂T_x flakes and their corresponding elemental maps of Ti, C, O and F elements. **c** XRD patterns and **d** Raman spectra of Ti₃AlC₂, S-Ti₃C₂T_x and O-Ti₃C₂T_x. **e** XPS survey spectra and high-resolution spectra with curve-fitting of S-Ti₃C₂T_x and O-Ti₃C₂T_x for **f** Ti 2p region, **g** O 1s region and **h** F 1s region

solutions of O-Ti₃C₂T_x products of different cycles to form free-standing Ti₃C₂T_x films (Fig. S1c). The electrochemical measurements were conducted by a three-electrode system in a Swagelok cell (Fig. S1d, e) with O-Ti₃C₂T_x films as working electrodes in an electrochemical capacitor. Cyclic voltammetry (CV) plots of the O-Ti₃C₂T_x film electrodes at 5 mV s⁻¹ (Fig. 5a) show appearance of redox peaks associating with the small cathodic and anodic peak potential separation (less than 50 mV), indicating that O-Ti₃C₂T_x

conforms with the pseudocapacitive charge storage behavior [28, 40, 41]. The galvanostatic charge–discharge (GCD) profiles show symmetric triangular curves at varied current densities, indicating fast and reversible electrochemical reactions (Fig. S11). Specific capacitances were calculated by integration of the discharge curves in the CV plots (Figs. 5b and S12) of different O-Ti₃C₂T_x film electrodes. At a scan rate of 2 mV s⁻¹, gravimetric capacitance values of all O-Ti₃C₂T_x products from different cycles are more

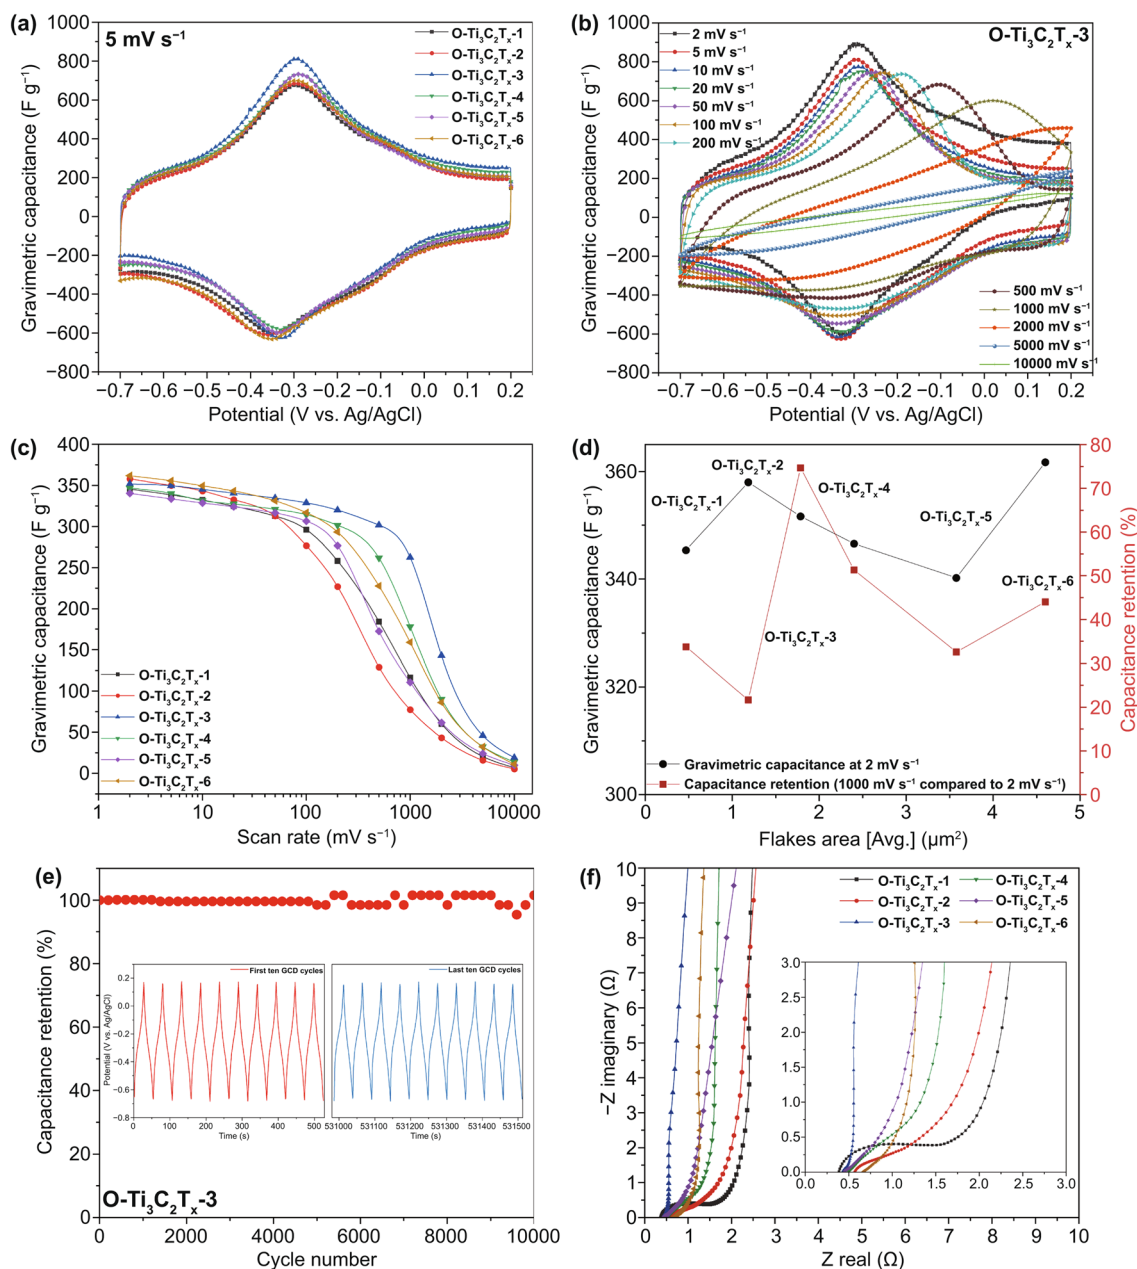

Fig. 5 Electrochemical performance of O-Ti₃C₂T_x film electrodes. **a** Cyclic voltammogram profiles collected in 3 M H₂SO₄ at 5 mV/s scan rate of O-Ti₃C₂T_x film electrodes from products of different cycles (denote as O-Ti₃C₂T_x-1 to O-Ti₃C₂T_x-6). **b** CV profiles of O-Ti₃C₂T_x-3 at scan rates from 2 mV s⁻¹ to 10 V s⁻¹. **c** Gravimetric capacitance of O-Ti₃C₂T_x film electrodes at different scan rates **d** Gravimetric capacitance at scan rate of 2 mV s⁻¹ and rate performance (scan rate at 1000 mV s⁻¹ compared to at 2 mV s⁻¹) of O-Ti₃C₂T_x film electrodes versus different flakes areas. **e** Capacitance stability of O-Ti₃C₂T_x-3 performed by GCD cycling at 10 A g⁻¹. The insets depict GCD cycling profiles collected at first ten cycles (red) and last ten cycles (blue), respectively. **f** Electrochemical impedance spectroscopy (EIS) for O-Ti₃C₂T_x film electrodes. The inset shows a magnification of the high-frequency region

than 340 F g⁻¹ (Fig. 5c), and volumetric capacitance values are up to 1100 F cm⁻³ (Fig. S13). A good rate performance was also observed, specifically, the O-Ti₃C₂T_x-3 outperformed others with a capacitance retention of 75% (at scan

rate of 1000 mV s⁻¹ compare to 2 mV s⁻¹, Fig. 5d). We also investigated the capacitive performance of S-Ti₃C₂T_x. As shown in Fig. S14, the gravimetric capacitance of S-Ti₃C₂T_x is ~ 300 F g⁻¹, which similarly with pristine

$\text{Ti}_3\text{C}_2\text{T}_x$ of previous reports [12, 18, 28, 42–45]. The gravimetric capacitances and rate performance of O- $\text{Ti}_3\text{C}_2\text{T}_x$ film electrodes were compared with pristine $\text{Ti}_3\text{C}_2\text{T}_x$ of previous reports and summarized in Table S3, which clearly demonstrate that O- $\text{Ti}_3\text{C}_2\text{T}_x$ products show outstanding capacitive performance. Using the best rate performing products of O- $\text{Ti}_3\text{C}_2\text{T}_x$ -3, the cyclic performance was also investigated. As shown in Fig. 5e, the O- $\text{Ti}_3\text{C}_2\text{T}_x$ -3 film electrode shows almost a 100% capacitance retention after 10,000 cycles at a GCD rate of 10 A g⁻¹.

In a previous work, Gogotsi et al. studied the size-dependent electrochemical properties of $\text{Ti}_3\text{C}_2\text{T}_x$ flakes [28]. For obtaining $\text{Ti}_3\text{C}_2\text{T}_x$ flakes with different sizes, they used solution-processable techniques to control and sort $\text{Ti}_3\text{C}_2\text{T}_x$ flakes after synthesis based on sonication and sucrose density gradient centrifugation, respectively. As one of the attractive features of this OAIC approach, the $\text{Ti}_3\text{C}_2\text{T}_x$ flakes with different sizes can be obtained in different production cycles instead of sonication and density gradient centrifugation, in order that provide an alternative approach to investigate the size-dependent electrochemical properties of $\text{Ti}_3\text{C}_2\text{T}_x$ flakes. We summarized the gravimetric capacitance (scan rate at 2 mV s⁻¹) and capacitance retention (scan rate at 1000 mV s⁻¹ compared to at 2 mV s⁻¹) of O- $\text{Ti}_3\text{C}_2\text{T}_x$ film electrodes with different flakes areas (corresponding flakes lateral sizes are shown in Fig. S6) in Fig. 5d. The O- $\text{Ti}_3\text{C}_2\text{T}_x$ -6 with largest flakes area shows the best specific capacitance of 362 F g⁻¹ (also for volumetric capacitance which is 1253 F cm⁻³) at the scan rate of 2 mV s⁻¹. However, from the perspective of the rate performance, the O- $\text{Ti}_3\text{C}_2\text{T}_x$ -3 with median flakes area outperforms others. The size-dependent electrochemical properties of $\text{Ti}_3\text{C}_2\text{T}_x$ have a compromise between the electrical conductivity and ion pathways of electrolyte. Specifically, although the larger $\text{Ti}_3\text{C}_2\text{T}_x$ flakes have higher electrical conductivity which heighten the charge transfer thereby boosting the capacitive performance [28], the film electrodes prepared by larger $\text{Ti}_3\text{C}_2\text{T}_x$ flakes suffer from long ion transport pathways resulting the poor rate performance [42]. Therefore, the O- $\text{Ti}_3\text{C}_2\text{T}_x$ -3 with median flakes area finds a balance between the good electrical conductivity and the less hinder of ion transport of electrolyte. The electrochemical impedance spectra (EIS) of O- $\text{Ti}_3\text{C}_2\text{T}_x$ -1 to O- $\text{Ti}_3\text{C}_2\text{T}_x$ -6 film electrodes are shown in Fig. 5f, which is highly consistent with the electrical conductivity and capacitance performance. From the high-frequency region in Fig. 5f, the

O- $\text{Ti}_3\text{C}_2\text{T}_x$ -1 and O- $\text{Ti}_3\text{C}_2\text{T}_x$ -2 possess a comparatively larger diameter of semicircle arc which related to charge transfer resistance (R_{ct}) due to the lower electrical conductivity. From O- $\text{Ti}_3\text{C}_2\text{T}_x$ -3 to O- $\text{Ti}_3\text{C}_2\text{T}_x$ -6, the Nyquist plots have relatively lower R_{ct} corresponding to the good electrical conductivity [28, 46]. The 45° slopes of the O- $\text{Ti}_3\text{C}_2\text{T}_x$ -3 are shorter than others, indicating the shorter ion transport pathways [28]. The straight line of O- $\text{Ti}_3\text{C}_2\text{T}_x$ -3 is almost parallel to the imaginary axis, indicating the rapid ion diffusion corresponding to the good rate performance [42, 45].

4 Conclusions

In summary, a new approach (OAIC) developed to prepare $\text{Ti}_3\text{C}_2\text{T}_x$ MXene has several remarkable features, including gram-level preparation with high yield (~46.3%), controllable flakes size (0.47–4.60 μm²), higher safety (toxic HF free), a good electrical conductivity (8,672 S cm⁻¹), an outstanding capacitive performance (352 F g⁻¹), and less requirement for facilities (high-speed centrifugation-free). The morphology, crystal phase, chemical bonds and elemental information of the products have been thoroughly studied by SEM/TEM, XRD/SAED, Raman spectrum/XPS, and EDS, respectively. To our knowledge, this novel OAIC approach makes a good trade-off between laboratory operation, requirement for facility, and product quality, which not only gives an excellent example regarding the synthesis of other MXene materials, but also sheds new light on the mass production of $\text{Ti}_3\text{C}_2\text{T}_x$ MXene in the future.
