3  
4 31 **Abstract:**

5 32 **Background:** The current global coronavirus disease 2019 (COVID-19) pandemic caused by severe  
6  
7 33 acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has shown limited responses to medical  
8  
9 34 treatments.

10  
11 35 **Aims:** To observe the effect of combination treatment of giammonium glycyrrhizinate and vitamin  
12  
13 36 C (DV) on the prognoses of patients with COVID-19.

14  
15 37 **Methods:** This retrospective observational study recruited 207 COVID-19 patients from Tongji  
16  
17 38 Hospital, patients were assigned to DV and non-DV groups on the basis of the DV treatment. To  
18  
19 39 make the results more credible, a propensity-score matching (PSM) approach was adopted at a 1:3  
20  
21 40 ratio to determine the participants. Logistic analysis was used to assess the effect of DV therapy in  
22  
23 41 the progress of COVID-19.

24  
25 42 **Results:** In the DV group, the new onset incidence rate of acute respiratory distress syndrome  
26  
27 43 (ARDS) after admission was clearly lower than that in the non-DV group (DV vs non-DV groups,  
28  
29 44 15.2% vs 35.7%; P=0.002). Compared with the non-DV group, the DV group showed fewer new  
30  
31 45 onset of complications (such as ARDS, acute liver injury and acute myocardial injury) (DV vs non-  
32  
33 46 DV groups, 19.6% vs 46.1%; P=0.000). Moreover, DG+VC may help to recover the count of NK  
34  
35 47 cells and decrease the level of sIL-2R.

36  
37 48 **Conclusions:** DG+VC might be a promising candidate for preventing the deterioration of COVID-  
38  
39 49 19 patients, which is worthy to be studied in large and perspective cohort.

## 61 **Introduction**

62 The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), causing coronavirus  
63 disease 2019 (COVID-19), has resulted in a global pandemic. Given the outbreak reaching epidemic  
64 proportions and the limited effective therapy, alternative medicine is urgently needed [1-2]. A recent  
65 bioinformatics analysis predicted that glycyrrhizic acid (GA) and vitamin C (VC) combinatorial  
66 treatment for COVID-19 is associated with elevated immunity and suppressed inflammatory stress,  
67 including the activation of the T cell receptor signaling pathway and the regulation of Fc gamma R-  
68 mediated phagocytosis [3]. GA is a major bioactive ingredient extracted from *Rhizoma*  
69 *Glycyrrhizae*, has potent pharmacological efficacy against viral infections and regulates the immune  
70 response [4-5]. During the SARS outbreak in 2003, it was reported that GA could effectively inhibit  
71 the replication, adsorption and penetration of two clinical isolates of SARS-associated coronavirus  
72 (FFM-1 and FFM- 2) in Vero cells. Diammonium glycyrrhizinate (DG) is a derivative of  
73 glycyrrhizic acid (GA). With a chemical structure similar to those of corticosteroids, DG functions  
74 as a glucocorticoid-like agent that might have an effect on cytokine storms or inflammation with  
75 few reported side effects [6].

76 Vitamin C supplements possess antiviral and immune-supportive properties, making this  
77 compound useful for preventing various conditions [7]. During the SARS epidemic, VC was  
78 recommended as a preventive medication and adjuvant therapy that significantly lowered the  
79 incidence of pneumonia [8]. A randomized controlled trial of 56 critical COVID-19 patients who  
80 received intravenous vitamin C at a dose of 12 g/50 ml every 12 hours for 7 days reported a  
81 diminishing trend in 28-day mortality [9]. However, high-dose VC may have side effects, including  
82 oxalate nephropathy, hypernatremia and nephrolithiasis [10]. Therefore, a regular dose of VC oral  
83 administration was preferred in this study and we supposed that DG+VC may enhance their  
84 effectiveness while minimizing the side effects.

## 85 **Method**

### 86 **Patient involvement**

87 This retrospective, single-centre, observational study enrolled 207 COVID-19 patients from  
88 Tongji Hospital at Huazhong University of Science & Technology (Wuhan, China) during February  
89 11 and March 31st, 2020. The diagnosis and severity of COVID-19 were based on the New  
90 Coronavirus Pneumonia Prevention and Control Program (Trial Version 5) published by the

1  
2  
3  
4 91 National Health Commission of China. Patients who met any of the following criteria were excluded:  
5  
6 92 1) younger than 18 years old; 2) short hospital duration of less than 7 days; and 3) testing negative  
7  
8 93 for SARS-CoV-2 viral infection. The study complied with the edicts of the 1975 Declaration of  
9  
10 94 Helsinki and was approved by the principal investigator center, Institutional Review Board of Ruijin  
11  
12 95 Hospital, Shanghai Jiao Tong University School of Medicine (No.:(2020) Linlun-34th). Written  
13  
14 96 informed consent was obtained from patients or their immediate relatives.

15 97 According to the COVID-19 guidelines, COVID-19 severity is classified as follows:

16  
17 98 1. Mild cases

18  
19 99 The clinical symptoms were mild, and there was no sign of pneumonia upon imaging.

20  
21 100 2. Moderate cases

22  
23 101 Showing fever and respiratory symptoms with radiological findings of pneumonia.

24  
25 102 3. Severe cases

26  
27 103 Adult cases meeting any of the following criteria;

28  
29 104 1) Respiratory distress ( $\geq 30$  breaths/ min);

30  
31 105 2) Oxygen saturation  $\leq 93\%$  at rest;

32  
33 106 3) Arterial partial pressure of oxygen ( $\text{PaO}_2$ )/fraction of inspired oxygen ( $\text{FiO}_2$ )  $\leq 300$  mmHg (l  
34  
35 107 mmHg=0.133 kPa).

36  
37 108 4. Critical cases

38  
39 109 Cases meeting any of the following criteria:

40  
41 110 1) Respiratory failure requiring mechanical ventilation;

42  
43 111 2) Shock;

44  
45 112 3) Other organ failure requiring ICU care.

46  
47 113 The severity of each case was defined based on the clinical information collected upon  
48  
49 114 admission.

50  
51 115 **Data Collection**

52  
53 116 The patients' data were collected between February 11 and March 31st, 2020. We recorded  
54  
55 117 participants' demographic information, symptoms, physical examination, comorbidities, routine  
56  
57 118 laboratory examinations, treatment and outcomes. All of the information was extracted from  
58  
59 119 electronic medical records or through direct communication with the patients and their health care  
60  
120 providers. Two physicians independently reviewed the data, and a third researcher decided whether

1  
2  
3  
4 121 there was any difference in data collection between the two primary reviewers.

5  
6 122 **DG plus VC treatment and group assignment**

7  
8 123 In this study, the eligible patients under study were categorized into the DV group and the non-  
9  
10 124 DV group. Patients in the DV group received DG (150mg Tid po) + VC (500 mg Tid po) treatment  
11  
12 125 continuously for at least 7 days within 48 hours after hospital admission. The remaining patients,  
13  
14 126 who were not treated with DG+VC were defined as the non-DV group. Diammonium  
15  
16 127 glycyrrhizinate has been used for more than 40 years as treatment for liver diseases with few  
17  
18 128 reported side effects. Thus, diammonium glycyrrhizinate at clinical dose of 150mg Tid po was  
19  
20 129 added to the standard therapy of COVID-19 patients in this study. Given that majority of patients  
21  
22 130 on admission were mild cases, and the uncertain side effects of high-dose intravenous vitamin C in  
23  
24 131 COVID-19 patients, a regular dose of VC oral administration (500 mg Tid po) was adopted in this  
25  
26 132 study.

27  
28 133 **Co-interventions**

29  
30 134 The treatment given to inpatients with COVID-19 followed the Diagnosis and Treatment  
31  
32 135 Protocol for Novel Coronavirus Pneumonia (Trial Version 5). All of the patients received antiviral  
33  
34 136 therapy, and arbidol was the most frequently used antiviral drug among our participants.  
35  
36 137 Glucocorticoids were given to patients with a progressive deterioration of oxygenation indicators,  
37  
38 138 rapid progress in imaging or excessive activation of the patient's inflammatory response. Invasive  
39  
40 139 mechanical ventilation was considered when conditions did not improve or even worsened within a  
41  
42 140 short time (1-2 hours) after receiving standard oxygen therapy, high-flow nasal cannula oxygen  
43  
44 141 therapy or non-invasive ventilation. When the outcome of prone position ventilation is poor,  
45  
46 142 extracorporeal membrane oxygenation (ECMO) was adopted. The indications for CRRT include:  
47  
48 143 1) hyperkalaemia; 2) acidosis; 3) pulmonary oedema or water overload; and 4) fluid management  
49  
50 144 in multiple organ dysfunction. Critical cases can be given an intravenous infusion of  $\gamma$ -globulin.

51  
52 145 **Definitions**

53  
54 146 ARDS was defined according to the Berlin definition [11]. Liver injury was defined according  
55  
56 147 to the ACG Clinical Guideline [12]. Acute myocardial injury was diagnosed if the serum levels of  
57  
58 148 cardiac biomarkers (e.g., troponin I) were above the 99th percentile upper reference limit or new  
59  
60 149 abnormalities were shown by electrocardiography and echocardiography [13]. Shock was defined  
150  
150 150 according to The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis-3)

1  
2  
3  
4 151 [14]. Acute kidney injury was identified and classified on the basis of the highest serum creatinine  
5  
6 152 level or urine output criteria according to kidney disease, improving the global outcome  
7  
8 153 classification [15].

#### 9 154 **Outcomes**

11 155 The primary outcome was the composite end point. The composite end point was either death  
12  
13 156 or requiring invasive mechanical ventilation. The secondary outcomes were complications,  
14  
15 157 including ARDS, liver injury, acute myocardial injury, acute kidney injury and septic shock.

#### 17 158 **Statistical analysis**

19 159 Propensity score matching was performed in the current study. We calculated a propensity  
20  
21 160 score using patients' sex and age in a logit model and used the nearest-neighbour matching method  
22  
23 161 without replacement at a ratio of 1:3 within a caliper of 0.01. Absolute standardized differences  
24  
25 162 were used to assess the performance of the matching, in which  $\leq 10\%$  was considered to be  
26  
27 163 negligible imbalances between the DV and non-DV groups. Then, the clinical characteristics were  
28  
29 164 compared before and after the propensity score matching (Table S1).

31 165 Firstly, we defined risk factors for COVID-19 according to previous studies, as follows:  
32  
33 166 age $\geq 60$  years, male sex, comorbidities (diabetes, hypertension, and chronic cardiovascular disease),  
34  
35 167 elevated IL-6, elevated LDH, elevated D-dimer and decreased lymphocytes [16-18]. Glucocorticoid  
36  
37 168 therapy and infusion of  $\gamma$ -globulin therapy are closely related to the progression of COVID-19, thus,  
38  
39 169 we also defined them as covariates [19-20]. Secondly, a univariate logistic analysis was used to  
40  
41 170 screen out the significant variables of these covariates ( $P < 0.5$ ) for further multivariate analysis.  
42  
43 171 Thirdly, to determine the performance of the DG+VC treatment, significant variables were included  
44  
45 172 in the multivariate logistic regression model, which was performed using a backward stepwise  
46  
47 173 approach after propensity score matching. Akaike information criterion (AIC) values were used to  
48  
49 174 assess the performance of parametric models. Thus, there were two logistic regression models for  
50  
51 175 composite endpoints and complications respectively in this research. It was noteworthy that  
52  
53 176 glucocorticoid therapy and the infusion of  $\gamma$ -globulin therapy were irrelevant to new onset  
54  
55 177 complications of COVID-19 because the majority of patients received these therapies after new  
56  
57 178 onset complications. Therefore, glucocorticoid therapy and  $\gamma$ -globulin infusion were not included  
58  
59 179 in the logistic model for complications.

60 180 A generalized estimation equation approach was adopted to perform a comparison of the

1  
2  
3  
4 181 dynamic changes in laboratory tests among patients who received treatment or those who did not.

5 182 Continuous variables are presented as the median and interquartile range (IQR). Categorical  
6  
7 183 variables are described as numbers and percentages. SPSS (version 26.0) and R (Version 3.5.3)  
8  
9 184 were used for all the statistical analyses. A two-sided  $\alpha$  value of  $< 0.05$  was considered statistically  
10  
11 185 significant.

## 13 186 **Results**

### 15 187 **Characteristics of participants**

17 188 A total of 302 patients were admitted to Tongji Hospital at Huazhong University of Science &  
18  
19 189 Technology (Wuhan, China) during February 11 through March 31st, 2020. Among them, 29  
20  
21 190 patients were not diagnosed with COVID-19. A further 53 records were excluded due to missing  
22  
23 191 treatment history or laboratory examination, and 13 cases were excluded for short hospital duration  
24  
25 192 of less than 7 days. Finally, the remaining 207 records were included in the study(Figure1).

27 193 Propensity score matching yielded 46 subjects in the DV group, who matched with 105  
28  
29 194 subjects in the non-DV group. Of the 161 inpatients with COVID-19 after propensity score  
30  
31 195 matching, the median age was 61 (54–69) years, and 47.2% were male. Patients defined as moderate,  
32  
33 196 severe and critical illness were 73.3%, 24.2%, 2.5%, respectively. In this PSM based nested case-  
34  
35 197 control study, there were no significant differences between the DV group and non-DV group in  
36  
37 198 terms of demographics, clinical characteristics, incidence of comorbidities, severity of illness or  
38  
39 199 laboratory tests upon admission (all  $P>0.05$ , Table 1). Compared with the DV group, there were  
40  
41 200 more severely ill patients who needed glucocorticoid therapy in the non-DV group (DV vs non-DV  
42  
43 201 group, 8.7% vs 27.8%;  $P=0.008$ , Table 1).

### 44 202 **Outcomes**

46 203 The incidence of primary endpoint was 9.3% among all patients and 2.2% among patients  
47  
48 204 received DG+VC therapy. Complication rate of all patients was 38.5% and 19.6% among patients  
49  
50 205 received DG+VC treatment (Table1). By using logistic regression, we found that DV therapy was  
51  
52 206 univariably associated with less complications (DV vs non-DV groups 19.6% vs 46.1%;  $P=0.000$ ;  
53  
54 207 odds ratio, 0.29; 95% confidence interval, 0.13-0.64, Supplementary table1).

56 208 Factors associated with primary endpoint and complications were included in the multivariate  
57  
58 209 regression model and listed in Supplementary table2 and Supplementary table3.The multivariate  
59  
60 210 regression analysis that adjusted for major risk factors suggested that the DG+VC treatment had no

1  
2  
3  
4 211 influence in relation to the death rate or the use of invasive mechanical ventilation (DV vs non-DV  
5 212 groups, 2.2% vs 12.2%; P=0.74, Table 2). However, in the DV group, the new onset incidence rate  
6 213 of acute respiratory distress syndrome (ARDS) after admission was clearly lower than that in the  
7 214 non-DV group (DV vs non-DV groups 15.2% vs 35.7%; P=0.002; odds ratio, 0.19; 95% confidence  
8 215 interval, 0.06-0.5, Table 2). Compared with the non-DV group, the DV group showed fewer new  
9 216 onset of complications (such as ARDS, acute liver injury and acute myocardial injury) (DV vs non-  
10 217 DV groups, 19.6% vs 46.1%; P=0.000; odds ratio, 0.15; 95% confidence interval, 0.05-0.39, Table  
11 218 2).

### 19 219 **Immunologic features**

20  
21 220 We assessed the immune state including proinflammatory factors (IL-1 $\beta$ , IL-6, IL-8, TNF- $\alpha$ ),  
22 221 anti-inflammatory cytokine (IL-10), sIL-2R and the number of immune cells (T cells, B cells,  
23 222 NK cells). All the values were collected from electronic medical records three times or four times  
24 223 with an interval of approximately one week during patients' hospitalization.

25  
26  
27  
28  
29 224 The dynamic changes of proinflammatory factors and IL-10 had no difference between DV  
30 225 and non-DV groups. Compared with non-DV patients, the count of NK cells showed better recovery  
31 226 in DV group (DV vs non-DV groups, mean value changed from 275.9/ul to 372.6/ul vs 215.8/ul to  
32 227 145.3/ul, P=0.03, Table 3) and the sIL-2R level was decreased to reach lower in the DV group after  
33 228 admission (DV vs non-DV groups, mean value fell from 597.7 pg/mL to 349.9 pg/mL vs from 797.6  
34 229 pg/mL to 572.2 pg/mL, P=0.02, Table 3).

### 40 230 **Discussion**

41  
42  
43 231 In this single-centre observational study, administration of VC (orally 500 mg 3 times daily)  
44 232 combined with DG (orally 150 mg 3 times daily) treatment was associated with lower incidence of  
45 233 new onset complications including ARDS, acute liver injury and acute myocardial injury in  
46 234 COVID-19 inpatients. Besides, this combined treatment could accommodate immunologic function,  
47 235 including help restore NK cells and decrease the plasma level of sIL-2R. We haven't observed the  
48 236 effect of the combined treatment on either death or requirement for invasive mechanical ventilation.

49  
50  
51  
52  
53  
54 237 SARS-CoV-2 was associated with organ dysfunction such as ARDS, acute heart injury, acute  
55 238 kidney injury, shock and acute liver injury, significant cases progressed rapidly to severe forms  
56 239 [21]. It was showed that the patients with SARS-CoV2-associated ARDS had extremely low level  
57  
58  
59  
60 240 of vitamin C. The latest research comprised 18 adult ICU patients COVID-19 who met ARDS

1  
2  
3  
4 241 criteria according to the Berlin definition. Vitamin C levels of seventeen patients (94.4%) were  
5  
6 242 undetectable and 1 patient had low levels (2.4 mg/L) [22]. Two therapeutic trials of Vitamin C  
7  
8 243 against COVID-19 were identified. One was an RCT with critically ill COVID-19 patients, finding  
9  
10 244 a dose of intravenous vitamin C of 24 g/day for 7 days could improve the ratio of PaO<sub>2</sub>/FiO<sub>2</sub> over  
11  
12 245 time, decrease the level IL-6 level, prevent worsening disease and reduce mortality. Another one is  
13  
14 246 case series of high-risk COVID-19 patients who were requiring at least 30% of FiO<sub>2</sub> or more. A  
15  
16 247 total of 17 patients were received intravenous vitamin C which was administered at a dose of 1 g  
17  
18 248 every 8 h for 3 days intravenously. It noted a significant decrease in inflammatory markers,  
19  
20 249 including ferritin and D-dimer, and a trend to decreasing FiO<sub>2</sub> requirements after vitamin C  
21  
22 250 administration [23].

23 251 A recent case report, reporting a case of severe COVID-19 who was failed to relieve under the  
24  
25 252 regular COVID-19 treatment in the hospital but improved overtime after taking VC (orally 200 mg  
26  
27 253 3 times daily) combined with DG (orally 150 mg 3 times daily) treatment regimen for eight  
28  
29 254 consecutive days [24]. However, the mechanism for the combination treatment remains unclear. A  
30  
31 255 recent bioinformatics analysis predicted that GA and vitamin C (VC) combinatorial treatment for  
32  
33 256 COVID-19 is associated with elevated immunity and suppressed inflammatory stress, including the  
34  
35 257 activation of the T cell receptor signaling pathway, the regulation of Fc gamma R-mediated  
36  
37 258 phagocytosis, the ErbB signaling pathway and the vascular endothelial growth factor signaling  
38  
39 259 pathway [3]. Consistent with this research, another system biology analysis found that combination  
40  
41 260 of Vitamin C, Curcumin and Glycyrrhizic Acid could regulate immune response by acting on NOD-  
42  
43 261 like and Toll-like signaling pathways to promote interferons production, activate and balance T-  
44  
45 262 cells to combat CoV infections and inhibit excessive inflammatory responses by inhibiting  
46  
47 263 PI3K/AKT, NF-κB and MAPK signaling pathways to prevent the onset of cytokine storm[25].Our  
48  
49 264 results implied that DG+VC may influence the level of sIL-2R and help to regulate the inflammatory  
50  
51 265 response. DV+VC also may recover the number of NK cells and enhance immune defenses against  
52  
53 266 COVID-19.

54 267 There were several limitations to this work. First, our study was a unicentric retrospective  
55  
56 268 observational study with limited sample size, which reduces the precision of the efficacy estimates.  
57  
58 269 Secondly, data on the monitoring of serum vitamin C and diammonium glycyrrhizinate as well as  
59  
60 270 related metabolites' concentration were unavailable during hospitalization.

1  
2  
3  
4 271 In conclusion, we shared preliminary evidence that DG+VC could reduce the incidence of  
5  
6 272 new-onset complications in COVID-19 patients, and might influence the immune response in these  
7  
8 273 patients. Our results suggested that combined treatment of DG +VC might be a low-cost, less side  
9  
10 274 effect promising candidate for preventing the deterioration of COVID-19 patients, awaiting large  
11  
12 275 and perspective cohort to confirm.

### 13 276 **Abbreviations**

14  
15 277 COVID-19: Coronavirus disease 2019 infection; SARS-CoV-2: severe acute respiratory syndrome  
16  
17 278 coronavirus 2; GA: glycyrrhizic acid; VC: vitamin C; DG: Diammonium glycyrrhizinate; CVD:  
18  
19 279 Chronic cardiovascular disease; COPD: Chronic obstructive pulmonary disease; CKD: Chronic  
20  
21 280 kidney disease; ALT: glutamic pyruvic transaminase; AST: glutamic oxaloacetic transaminase;  
22  
23 281 LDH: lactate dehydrogenase; T-pro-BNP: T-pro brain natriuretic peptide. *PMS*: Propensity score  
24  
25 282 matching; *DV*: giammonium glycyrrhizinate and vitamin C

### 26 27 283 **Ethical approval**

28  
29 284 The study complied with the edicts of the 1975 Declaration of Helsinki and was approved by the  
30  
31 285 principal investigator center, Institutional Review Board of Ruijin Hospital, Shanghai Jiao Tong  
32  
33 286 University School of Medicine (No.(2020) Linlun-34th). Informed consent was obtained from all  
34  
35 287 subjects or if subjects are under 16, from a parent and/or legal guardian.

### 36 37 288 **Consent for publication**

38  
39 289 Not applicable.

### 40 41 290 **Availability of data and materials**

42  
43 291 The datasets used in this study are available from the corresponding author on reasonable request.
