## ABSTRACT

#### Background

Cell transplantation offers a potential therapeutic approach to the repair and regeneration of damaged vascular and cardiac tissue after acute myocardial infarction (AMI). This has resulted in multiple randomised controlled trials (RCTs) across the world.

#### Objectives

To determine the safety and efficacy of autologous adult bone marrow stem cells as a treatment for acute myocardial infarction (AMI), focusing on clinical outcomes.

#### Search methods

This Cochrane review is an update of a previous version (published in 2012). We searched the Cochrane Central Register of Controlled Trials (CENTRAL 2015, Issue 2), MEDLINE (1950 to March 2015), EMBASE (1974 to March 2015), CINAHL (1982 to March 2015) and the Transfusion Evidence Library (1980 to March 2015). In addition, we searched several international and ongoing trial databases in March 2015 and handsearched relevant conference proceedings to January 2011.

## **Selection criteria**

RCTs comparing autologous bone marrow-derived cells with no cells in patients diagnosed with AMI were eligible.

## Data collection and analysis

Two review authors independently screened all references, assessed the risk of bias of the included trials and extracted data. We conducted meta-analyses using random-effects models throughout. We analysed outcomes at short-term (less than 12 months) and long-term (12 months or more) follow-up. Dichotomous outcomes are reported as risk ratio (RR) and continuous outcomes are reported as mean difference (MD) or standardised MD (SMD). We performed sensitivity analyses to evaluate the results in the context of the risk of selection, performance and attrition bias. Exploratory subgroup analysis investigated the effects of baseline cardiac function (left ventricular ejection fraction, LVEF) and cell dose, type and timing of administration, as well as the use of heparin in the final cell solution.

#### **Main results**

Forty-one RCTs with a total of 2732 participants (1564 cell therapy, 1168 controls) were eligible for inclusion. Cell treatment was not associated with any changes in the risk of all-cause mortality (34/538 versus 32/458; RR 0.93, 95% CI 0.58 to 1.50; 996 participants; 14 studies; *moderate quality evidence*), cardiovascular mortality (23/277 versus 18/250; RR 1.04, 95% CI 0.54 to 1.99; 527 participants; nine studies; *moderate quality evidence*) or a composite measure of mortality, reinfarction and re-hospitalisation for heart failure (24/262 versus 33/235; RR 0.63, 95% CI 0.36 to 1.10; 497 participants; six studies; *moderate quality evidence*) at long-term follow-up. Statistical

heterogeneity was low ( $l^2 = 0\%$  to 12%). Serious periprocedural adverse events were rare and were generally unlikely to be related to cell therapy. Additionally, cell therapy had no effect on morbidity, quality of life/performance or LVEF measured by magnetic resonance imaging. Meta-analyses of LVEF measured by echocardiography, single photon emission computed tomography and left ventricular angiography showed evidence of differences in mean LVEF between treatment groups although the mean differences ranged between 2% and 5%, which are accepted not to be clinically relevant. Results were robust to the risk of selection, performance and attrition bias from individual studies.

#### **Authors' conclusions**

The results of this review suggest that there is insufficient evidence for a beneficial effect of cell therapy for AMI patients. However, most of the evidence comes from small trials that showed no difference in clinically relevant outcomes. Further adequately powered trials are needed and until then the efficacy of this intervention remains unproven.

## PLAIN LANGUAGE SUMMARY

#### Stem cell treatment following a heart attack

Review question: Are bone marrow cells safe and effective as a treatment following a heart attack?

**Background:** Currently the standard treatment for people suffering a heart attack (due to a blockage in the artery supplying blood to the heart) is direct opening of the artery with a tiny balloon in a procedure called primary angioplasty and introduction of a small tube (called a stent) into the artery to keep it open. The use of primary angioplasty and stents to reopen the blocked artery can lead to a 35% reduction in the mortality (death rate) associated with this condition. In recent years, bone marrow stem/progenitor cells have been investigated as a potential treatment. They may prevent the damage to the heart muscle caused by a heart attack, when used in addition to the treatment offered by primary angioplasty and standard medical therapy.

**Study characteristics:** Randomised trials comparing bone marrow-derived cells with no cells in patients diagnosed with acute myocardial infarction were eligible for this review. We searched databases to March 2015. This review was supported by the National Institute of Health Research (NIHR) through its Cochrane Incentive Award programme.

**Key results:** In this updated systematic review we analysed data from a total of 41 trials with over 2700 patients. Evaluation of the currently available evidence indicates that this treatment may not lead to improvement when compared to standard treatment, as measured by the frequency of deaths, heart attacks and/or heart failure requiring re-hospitalisation following treatment, as well as tests of heart function, in the short and long term.

Quality of evidence for primary outcomes: The evidence in this review is of moderate quality due to the small number of events.

## SUMMARY OF FINDINGS

Summary of findings for the main comparison. Cells compared to no cells for acute myocardial infarction (AMI)

Cells compared to no cells for acute myocardial infarction (AMI)

Patient or population: patients with AMI

Settings: Hospitalised patients

Intervention: cells

\*The **assumed risk** is based on the observed incidence across the pooled control groups. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI). **CI:** confidence interval; **RCT:** randomised controlled trial; **RR:** risk ratio

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

**Moderate quality:** Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

<sup>1</sup>Imprecision: information size criterion not met. Small size effect.

Cochrane Library

Trusted evidence. Informed decisions. Better health.

## BACKGROUND

## **Description of the condition**

Despite major advances in treatment regimes, ischaemic heart disease remains a major cause of mortality and morbidity worldwide (BHF 2014). In the UK alone there are more than 2.3 million people living with ischaemic heart disease, causing approximately 153 deaths for every 100,000 people and representing a substantial cost to our healthcare system (BHF 2014). For example, more than GBP 6.8 billion was spent on treating the disease within NHS England in 2012/2013 (BHF 2014). The main symptom of ischaemic heart disease is a heart attack or myocardial infarction. Acute myocardial infarction (AMI) most often occurs when there is rupture of an atherosclerotic plaque into a coronary artery, which may cause thrombosis and occlusion of the artery, stopping the blood supply in that region of the heart and causing necrosis of the affected area (Falk 1995). Subsequently, both infarcted and unaffected myocardium undergo adverse remodelling that can sometimes extend to the entire ventricular wall. The first changes occur almost immediately after coronary occlusion and lead to loss of contractility, followed by the growth of the necrotic areas in the following days. The infarcted region would have healed after two to three months, leaving a scar (fibrotic, non-contracting region) in the ventricular wall (ESC/ACC 2000).

Current medical treatment can ameliorate the symptoms of the disease. First thrombolytic therapy and, most recently, primary angioplasty have become the standard treatment choice for those suffering from AMI. However, although optimal medical therapy reduces mortality (Hartwell 2005), patients continue to face risks of heart failure following heart attacks (Velagaleti 2008). Therefore, the search for treatment options that prevent this adverse ventricular remodelling following AMI has been at the forefront of clinical research in cardiology.

## **Description of the intervention**

For more than a decade cell therapies have been developed as new treatments for patients suffering from AMI (Strauer 2002). The first non-randomised trials demonstrated the feasibility of infusing bone marrow-derived mononuclear cells (BMMNC) into the infarcted area of the myocardium via the infarct-related artery (IRA) using a procedure similar to percutaneous coronary intervention or PCI (Assmus 2002; Fernandez-Aviles 2004; Meyer 2006; Strauer 2002; Tse 2003). This was later expanded to the direct injection of cells into the ischaemic cardiac muscle during coronary artery bypass graft (CABG) (Stamm 2003). The study by Stamm in 2003 administered bone marrow-derived CD133+ haematopoietic progenitor cells and showed that these cells could improve revascularisation of the infarcted myocardium (Stamm 2003). The success of these first trials resulted in a number of larger randomised controlled clinical trials (RCTs) world-wide (Cao 2009; Gao 2013; Grajek 2010; Hirsch 2011; Janssens 2006; Lee 2014; Lunde 2006; Nogueira 2009; Roncalli 2010; Schachinger 2006; Sürder 2013; Tendera 2009; Traverse 2010; Traverse 2011; Traverse 2012; Wohrle 2010; Wollert 2004; Yao 2009). To date, the majority of RCTs infuse a pool of BMMNC, but recently the first placebo-controlled study comparing enriched CD34<sup>+</sup> haematopoietic progenitor cells with non-selected BMMNC has been published (Tendera 2009). In addition, bone marrow-derived mesenchymal stromal cells (BM- MSC) have been also tested in the clinic as a treatment for AMI (Gao 2013; Lee 2014).

Bone marrow harvest, containing the mononuclear cells and a small proportion of stem/progenitor cells (e.g. CD34<sup>+</sup> or CD133<sup>+</sup> enriched progenitor cells), is undertaken by a haematologist, whilst a specialised technician or scientist undertakes the isolation of the mononuclear cells or the selection of stem/progenitor cells. Finally, the cardiologist undertakes the infusion or injection of the cells.

Bone marrow harvest and isolation of BMMNC is a standard procedure in bone marrow transplantation for haematological malignancies. Cell transplantation in the context of heart disease is not currently available as standard clinical practice. The treatment is only available in research-associated facilities, whilst its safety and efficacy is tested, but it is conceivable that this procedure may be available to all myocardial infarction patients, if long-term effectiveness, prevention of heart failure and reduced morbidity are demonstrated.

The procedure at the current time is as follows: the bone marrow is harvested under general anaesthesia from the pelvic bone of the recipient using large suction needles. Thereafter, the BMMNC, CD34<sup>+</sup> or CD133<sup>+</sup> haematopoietic progenitor cells (BM-HPCs) are enriched away from other bone marrow cells in sterile conditions by a specialised technician or scientist. The bone marrow harvest and separation of stem cells may take several hours. Unlike BMMNC, BM-MSC have to be cultured in the laboratory for two to four weeks to obtain a large enough number of cells prior to their administration. The enriched or cultured cell populations are infused directly into the recipient's heart by a cardiologist during angioplasty (e.g. PCI) with a catheter allowing the administration of cells in a stop-flow technique via a special balloon catheter (Strauer 2002). The time interval between the removal of the cells from the participant and their reinfusion varies.

The costs of the intervention may be high depending on the procedures used, and currently relate to the costs of the cell procedure (cell harvest) and the costs of the isolation of the stem/ progenitor cells (approximately a 10th of the cost of the trial) or the cost of culturing cells in a dish.

## How the intervention might work

Regardless of intensive preclinical and clinical research in the field in the past decade, the mode of action of cell therapies has remained unclear or at least controversial. Although transplanted cells are thought to benefit heart function through direct mechanisms, such as homing to the site of injury and differentiating into neighbouring cardiac tissues (Leri 2009), there is growing evidence that their benefit might be indirect. There is presently a shift in the regenerative concept of cell therapies in heart disease towards the hypothesis that cell-based therapies primarily have a paracrine effect (for review see Bartunek 2010; Behfar 2014). Paracrine signalling is that in which the target cell is a different type of cell but it is close by the signal-releasing cell. Transplanted cells would produce stimulatory cytokines, which may increase vascularity and collateral growth, promote cardiomyocyte proliferation, limit or reduce fibrosis and/or activate endogenous resident stem cells (Bartunek 2010; Behfar 2014; Cheng 2014). This could lead to reverse remodelling of the infarcted tissue and reduction in scar size.

## Why it is important to do this review

In 2004, the first RCTs administering cell therapies as a treatment for AMI were reported (Chen 2004; Wollert 2004). Two years later, the number of RCTs published had increased significantly (Ge 2006; Huang 2006; Janssens 2006; Kang 2006; Karpov 2005; Lunde 2006; Ruan 2005; Schachinger 2006; Wollert 2004; Yao 2006). The first version of this review evaluated the clinical evidence from 13 RCTs, the majority of which had short-term follow-up (e.g. less than six months follow-up) (Martin-Rendon 2008a; Martin-Rendon 2008b). Those first-generation clinical trials were not powered to assess the effect of cell therapies on clinical outcomes such as mortality. The main aim of those trials was to assess the safety of the intervention and the benefit of the treatment, measuring left ventricular ejection fraction (LVEF) as surrogate outcome. We defined safety as the absence of adverse events (e.g. increased mortality and morbidity, increased risk of secondary infarction, restenosis and arrhythmias, development of heart failure) and efficacy as improvement in cardiac function associated with cell therapy.

The second version of this review, Clifford 2012, evaluated 33 RCTs and long-term follow-up data had started to emerge (Cao 2009; Grajek 2010; Jin 2008; Meluzin 2008; Penicka 2007; Piepoli 2010; Yao 2009; Zhukova 2009). In that update of the review we included 20 new studies. Unlike other systematic reviews where a total of 50 trials were assessed (Jeevanantham 2012), our systematic review was the first to determine that there was no evidence of a difference in the risk of mortality between treated participants and controls (Clifford 2012).

There is currently a high degree of uncertainty about the beneficial effect of cell therapies as treatment for AMI. Both RCTs (Hirsch 2011; Lunde 2006; Roncalli 2010; Schachinger 2006), and previous systematic reviews and meta-analyses (Clifford 2012; Delewi 2014; Gyöngyösi 2015; Jeevanantham 2012), have shown divergent results. Additionally, in light of recent studies suggesting that there are inconsistencies in the reporting of clinical trials and that the effect size of the treatment is correlated with the number of discrepancies (Nowbar 2014), it is even more important to review the clinical evidence thoroughly.

We have extracted and analysed data collected from the newly identified and included studies using the same methodology as described in the previous versions of the review (Clifford 2012; Martin-Rendon 2007; Martin-Rendon 2008a; Martin-Rendon 2008b). We have also carried out 'Risk of bias' assessment of the new included studies following the same methods as previously. We have performed a new meta-analysis that includes all 41 studies. In this version of the systematic review, we have reduced the number or surrogate outcomes analysed to focus on clinical outcomes, LVEF and quality of life outcomes. As it has become clear that cell therapies for AMI are safe and have no major adverse effects, the main questions to address in this systematic review are whether the intervention is efficacious and has a clinical benefit, and whether the findings from this systematic review can inform ongoing or future trials.

## OBJECTIVES

To determine the safety and efficacy of autologous adult bone marrow stem cells as a treatment for acute myocardial infarction (AMI), focusing on clinical outcomes.

## METHODS

## Criteria for considering studies for this review

#### **Types of studies**

Randomised controlled trials.

## **Types of participants**

Any participants with a clinical diagnosis of AMI with no restriction on age.

#### **Types of interventions**

Studies involving the administration of autologous adult bone marrow-derived cells following successful revascularisation by angioplasty or cardiac surgery.

Participants in the comparator treatment arm of the trial would have had either no intervention or placebo (e.g. medium where the stem cells are suspended, or plasma). Trials where surgery (e.g. coronary artery bypass graft (CABG)) or percutaneous angioplasty (e.g. PCI) have been administered were eligible.

#### In summary:

- any autologous human adult bone marrow stem cells;
- any method of stem/progenitor cell isolation or enrichment;
- any route of administration;
- any co-intervention (e.g. surgery or angioplasty); and
- any single dose or multiple doses of intervention.

#### Types of outcome measures

#### **Primary outcomes**

- All-cause mortality
- Cardiovascular mortality
- Composite measures of major adverse cardiac events (MACE)
- · Periprocedural adverse events

#### Secondary outcomes

- Morbidity including reinfarction, incidence of arrhythmias, incidence of restenosis, target vessel revascularisation and rehospitalisation for heart failure
- Quality of life and performance status (if measured separately from a quality of life measurement)
- Left ventricular ejection fraction (LVEF)

We assessed all outcomes at short-term (less than 12 months) and long-term (12 months or more) follow-up.

In this version of the review, we have focused on clinical outcomes. However, the surrogate endpoint of LVEF is a standard, widely reported surrogate for cardiac function and has been retained as a reference point with other trials and systematic reviews in AMI. Surrogate outcomes other than LVEF reported in previous versions of this review, namely engraftment and survival of the infused stem cells, left ventricular end-systolic volume, left ventricular end-diastolic volume, wall motion score, stroke volume index and infarct size, are no longer included as outcomes.

## Search methods for identification of studies

#### **Electronic searches**

We updated the searches, originally run in August 2007 (Appendix 1), in January 2011 (Appendix 2) and then again in March 2015 (Appendix 3). We identified relevant studies from searching the following:

- Cochrane Central Register of Controlled Trials (CENTRAL 2015, Issue 2);
- MEDLINE (OvidSP, 1946 to 11 March 2015);
- EMBASE (OvidSP, 1974 to 11 March 2015);
- CINAHL (EBSCOhost, 1982 to 11 March 2015);
- PubMed (for e-publications only, 11 March 2015);
- LILACS (1982 to 11 March 2015);
- KoreaMed (1997 to 11 March 2015);
- IndMed (1986 to 11 March 2015);
- PakMediNet (1995 to 11 March 2015);
- Web of Science: Conference Proceedings Citation Index Science (CPCI-S) (1990 to 11 March 2015).

#### Searching other resources

In addition, we carried out the following.

- Handsearching of conference abstracts from relevant heart and/ or stem cell conferences, e.g. the American Heart Association, International Society of Stem Cell Research (from 2005 to January 2011). Handsearching was not continued post-January 2011, as these conference abstracts are now included within EMBASE.
- Searches of three databases of ongoing trials, all performed on 11 March 2015:
- \* ClinicalTrials.gov (https://clinicaltrials.gov/);
- \* ISRCTN Register (http://www.isrctn.com/);
- \* World Health Organization (WHO) International Clinical Trials Registry Platform (ICTRP) (http://apps,who.int/trialsearch/).
- Searches of the reference lists of all identified eligible papers and relevant systematic and/or narrative reviews.

We applied no language or date restrictions.

#### Data collection and analysis

## Selection of studies

The information specialist (CD) conducted the electronic search for potentially relevant papers and removed references that were duplicates, clearly irrelevant and/or included in previous search results. Two review authors (SF, EMR for this update) independently screened all titles and abstracts of references identified by the review search strategy for relevancy to the review question. We exclude studies that clearly did not meet the eligibility criteria at this stage. Two review authors (SF, EMR) independently assessed all other studies on the basis of their full text for inclusion/exclusion using the criteria indicated above (type of studies, participants, interventions and outcome measures). We resolved disagreements through discussion.

#### **Data extraction and management**

Two review authors (SF, HZ for this update) extracted data onto customised data extraction forms, which we created and piloted specifically for this review, and undertook data extraction for all eligible studies independently. Aside from details relating to the quality of included studies, we extracted the following two groups of data:

- Trial characteristics: place of publication, date of publication, population characteristics, setting, detailed nature of intervention, detailed nature of comparator, detailed nature of outcomes. A key purpose of these data was to explain clinical heterogeneity between included studies independently from analysis of the results.
- Results of included studies for each of the main outcomes indicated in the review question. For dichotomous outcomes, we recorded the numbers of outcomes in the treatment and control groups. For continuous outcomes, we recorded the mean and standard deviation. Where standard deviations of mean change from baseline values were not explicitly reported, where possible we calculated the standard deviation based on reported confidence intervals or P values as described in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011), and we used these values in the analysis. In the writing of this version of the review we identified a systematic error in the previous versions of the review in the calculation of standard deviations for mean change from baseline values. This issue has now been corrected; the discrepancies between the correct and previously reported values were small in all cases. In some studies it was not possible to calculate the value of the standard deviation and imputation techniques were deemed unsuitable due to the relatively high proportion of studies with missing standard deviations in some analyses (Higgins 2011). These studies, previously analysed as mean change from baseline values, are now incorporated in combined analyses using the mean endpoint value.

We resolved data extraction disagreements by consensus between the review authors. When disagreements regarding any of the above could not be resolved through discussion, we attempted to contact authors of the original trials to provide further details (see Dealing with missing data below). We then transcribed the data into the systematic review computer software Review Manager 5.3 (Review Manager 2014).

In light of the number of studies included in the previous version of this review that have had additional publications since, we checked all previous data included in the review. This resulted in a number of minor data errors being identified; these are corrected in the current version of the review. These errors made a negligible difference to the previous results and did not affect the conclusions.

#### Assessment of risk of bias in included studies

Two review authors (SF, HZ for this update), undertaking the data extraction independently, assessed the risk of bias for each trial using the criteria outlined in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011). We assessed the design, conduct and analysis of the trial using a three-point scale: low, high or unclear risk of bias. To assess risks of bias, the authors included the following questions in the 'Risk of bias' table for each included trial:

Stem cell treatment for acute myocardial infarction (Review)

Copyright  $\ensuremath{\mathbb S}$  2015 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

- Was the allocation sequence adequately generated?
- Was allocation adequately concealed?
- Was knowledge of the allocated intervention adequately prevented (i.e. blinded) throughout the trial?
- Were incomplete outcome data adequately addressed for every outcome?
- Were reports of the trial free of selective outcome reporting?
- Was the trial apparently free of other problems that could put it at risk of bias?

For trials included in the previous version of this review, we reevaluated the risk of bias in the context of the revised outcomes and updated this accordingly. We resolved disagreements through discussion with a third review author.

A study of trials published in Chinese medical journals that were described as randomised found that a high proportion of these trials did not adhere to accepted methodology for randomisation and hence could not be deemed authentic RCTs (Wu 2009). It is now widely accepted that trials carried out in China may lack appropriate randomisation, therefore we deemed any Chinese studies for which methods of randomisation were not described and could not be clarified with trial authors to have a high risk of selection bias; we evaluated sensitivity to these trials through sensitivity analyses (see Sensitivity analysis section below).

## Unit of analysis issues

In the analysis of quality of life outcomes, we converted Minnesota Living with Heart Failure (MLHF) scores to negative values in order to include these in a meta-analysis with other measures on different scales using the standardised mean difference.

## Dealing with missing data

We sought clarification of the extent of possible participant overlap between potentially related studies from nine trial authors by email contact. Eight authors responded and we reached the following conclusions through email correspondence:

- Twenty treatment arm participants and 10 control arm participants were included in two trials published separately (Plewka 2009). Due to the extensive participant overlap and the shared protocol design of these two studies, we extracted and combined data as a single trial.
- In a large trial of 200 participants (Tendera 2009), 12 patients were also included in a separate trial (Grajek 2010). In view of the small degree of overlap, we have extracted data from these trials separately and included as them independent studies in this review.
- A 2014 publication by Ryabov et al was a long-term follow-up of an earlier trial already included in an early version of this review (Karpov 2005).
- A 2012 conference abstract published by Turan et al described long-term follow-up of an earlier trial reported in full (Turan 2012).

The following issues are awaiting resolution:

 The extent of possible participant overlap between two conference abstracts (Huang 2007b; Huang 2008), and four separate studies from the same research group (Ge 2006; Huang 2006; Huang 2007; Yao 2006), could not be confirmed as email contact with the authors was unsuccessful. As a result, we have listed both Huang 2007b and Huang 2008 as studies awaiting classification.

We contacted a further four authors of trials published in abstract form only at the time of study selection to establish whether these trials were expected to be published in full. Two of these trials have now been published in full (Hirsch 2011; Roncalli 2010), and we have since excluded one trial (Perez-Oteyza 2006). No further publications have been identified for the fourth trial (Fernandez-Pereira 2006); this trial is therefore included in studies awaiting classification. We contacted one trial author to clarify the publication of further follow-up data (Roncalli 2010).

We made attempts to contact the authors of 20 included studies by email requesting additional information on the trial design and methodology, clarification regarding data discrepancies, further detail about patient demographics and/or additional data (Cao 2009; Colombo 2011; Chen 2004; Huang 2006; Huang 2007; Janssens 2006; Jazi 2012; Jin 2008; Lunde 2006; Nogueira 2009; Piepoli 2010; Ruan 2005; Schachinger 2006; Sürder 2013; Tendera 2009; Turan 2012; Wang 2014; Wohrle 2010; Xiao 2012; Yao 2006). Authors of five trials kindly responded as follows; key data provided by authors included the following:

- Lunde 2006: mean change from baseline echocardiography, MRI and SPECT data were confirmed.
- Piepoli 2010: the number of participants included in the analyses and details of withdrawals and exclusions were clarified; mean and standard deviation values for echocardiography data were provided.
- Schachinger 2006: surrogate endpoint data from MRI at 24month follow-up were provided.
- Tendera 2009: mean and standard deviation values for MRI data were provided.
- Turan 2012: details of the number of withdrawals and exclusions with reasons were provided, together with clarification of patient demographics.

#### **Assessment of reporting biases**

Although we believe that we made every effort to identify unpublished studies, we assessed publication bias for the primary outcome of mortality using a funnel plot and with a formal test for publication bias using Egger's test for asymmetry (Egger 1997), implemented with the statistical software programme R v2.14.1 (R Core Team 2013).

## Data synthesis

We undertook meta-analyses using Review Manager 5.3 (Review Manager 2014), using random-effects models throughout due to the anticipated heterogeneity arising from differences in participant characteristics, interventions and duration of follow-up. This differs from the previous version of the review in which fixed-effect models were used for meta-analyses in the first instance. Although quantitative synthesis was the main method of analysis, we incorporated insights from a qualitative evaluation of studies for an overall interpretation of the data. We based conclusions on patterns of results identified across clearly tabulated results of included studies as well as summary measures, taking both direction and magnitude of any mean effect sizes from random-effects models into account. We included all studies in the main

Cochrane

analyses irrespective of risk of bias; we performed sensitivity analyses for risk of selection, performance and attrition bias as described in the Sensitivity analysis subsection below. We summarised periprocedural adverse events for each trial in tabular form and evaluated them descriptively.

Within each included trial, all participants were analysed in the treatment groups to which they had been randomised. We have undertaken an available case analysis, including all participants who were randomised to treatment and were included in the analysis, irrespective of whether or not they received their randomised treatment.

We carried out separate analyses according to the duration of follow-up after treatment: short-term (less than 12 months) and long-term (12 months or more). We expressed dichotomous data for each arm in a particular trial as a proportion or risk and the treatment effect as a risk ratio (RR) with 95% confidence intervals (CIs). We expressed continuous data for each arm in a particular trial as a mean and standard deviation, and the mean treatment effect as the mean difference (MD) if outcomes were measured in the same way across trials. For outcomes measured using different scales (physical capacity and quality of life measures), we combined the treatment effect data and analysed them using the standardised mean difference (SMD).

Although we intended to analyse continuous outcomes as mean change from baseline, several studies only reported baseline and endpoint data. Where possible, we calculated the standard deviation of the mean change from baseline based on reported confidence intervals or P values as described in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011), and we used these values in the analysis. However, for several studies, insufficient information was reported to calculate the standard deviation. The mean difference based on the change from baseline can be assumed to address the same underlying intervention effects as an analysis based on final measures (i.e. the differences in mean final values will on average be the same as the differences in mean change scores). Therefore we combined studies reporting mean change from baseline values with those reporting endpoint values (using preferentially mean change values where both were reported), but presented mean change and endpoint values separately as well as in combined analyses for clarity, as suggested in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011). We did not conduct this pooling of studies by method of reporting of continuous measures for analyses of quality of life or physical capacity, since the assumption of consistent underlying effects does not hold for standardised mean differences.

Six trials reported multiple intervention groups. In order to avoid double-counting of controls, in the main analyses we pooled data from active intervention arms across different doses (high dose/low dose (Meluzin 2008) or high/medium/low dose (Quyyumi 2011)), delivery routes (arterial or venous) (Nogueira 2009), timing of cell delivery (early or late) (Sürder 2013), type of cells (selected or unselected (Tendera 2009)) or number of cell doses (Yao 2009).

We produced a 'Summary of findings' table for the primary outcomes of all-cause mortality, cardiovascular mortality and the composite measure of major adverse clinical cardiac events at both short-term and long-term follow-up, using the GRADEpro GDT software (GRADEpro GDT 2014). We calculated risk ratios excluding trials with a high risk of randomisation sequence selection bias, assuming an underlying control risk from the observed data from included trials.

#### Trial sequential analysis

Cumulative meta-analyses may result in type I errors due to an increased risk of random error arising from repeated testing of accumulating data (Borm 2009; Hu 2007; Lan 2003). Trial sequential analysis provides a method of adjusting the thresholds for statistical significance while maintaining the overall desired type I error rate (Wettersley 2008). These adjusted thresholds are known as trial sequential monitoring boundaries (TSMBs). If the cumulative Z-curve crosses the TSMB, then statistical significance has been reached whilst maintaining the overall type I error rate. Futility boundaries may also be produced such that if the cumulative Z-curve crosses the futility threshold, there is evidence that the two treatments do not differ more than the anticipated effect size. Trial sequential analysis also provides a required information size, the meta-analysis information size needed to detect a statistically significant effect given a defined underlying model. We applied trial sequential analysis to the primary outcomes of all-cause mortality, cardiovascular mortality and composite MACE, assuming a long-term mortality incidence rate of 6.1% in the control group (as observed in our control data); we estimated control group incidence rates for cardiovascular mortality and composite MACE from the observed control data similarly. For each outcome we calculated the information size required for a relative risk reduction of 35% (equivalent to the reduce risk of mortality associated with PCI (Hartwell 2005). Using the TSA program (TSA 2011), we calculated two-sided TSMBs using the O'Brien-Fleming  $\beta$ -spending function for an overall 5% type I error rate and 80% power. We made a model variance based heterogeneity correction to incorporate the minimal heterogeneity observed for the outcomes of cardiovascular mortality and composite major adverse clinical events. We made no adjustment for heterogeneity for the outcome of mortality, consistent with the lack of heterogeneity observed in the meta-analysis. We produced no futility boundaries as the information fraction was too small to produce an inner wedge futility area from the trial sequential analysis program. We included studies that had reported outcomes at more than one long-term follow-up time point in the trial sequential analysis according to the time at which they first reported long-term follow-up (and hence were included in metaanalyses).

#### Subgroup analysis and investigation of heterogeneity

A range of different methods were used to measure LVEF across studies (magnetic resonance imaging (MRI), left ventricular angiography (LVA), single photon emission computed tomography (SPECT), echocardiography and radionuclide ventriculography (RNV)), with several studies reporting LVEF as an outcome using more than one method of measurement. The limitations of some of these methods are well known (Arnesen 2007). Consistent with the previous version of this review, we subgrouped analyses of LVEF according to the measurement method used.

We grouped trials according to baseline cardiac function (defined by mean baseline LVEF < 45% or  $\geq$  45%), mean cell dose ( $\leq$  10<sup>8</sup>, > 10<sup>8</sup> and  $\leq$  10<sup>9</sup>, > 10<sup>9</sup>), timing of stem cell administration (within 10 days or more than 10 days after AMI) and use of heparinised cell solution. Planned subgroup analysis of the type/route of cell delivery was not

possible as all but one trial, Nogueira 2009, administered cells into the coronary artery.

We performed a priori subgroup analyses for the primary outcome of mortality. For other outcomes with substantial observed heterogeneity ( $I^2 \ge 50\%$ ) (Higgins 2003), and a minimum of two studies in each subgroup, we investigated potential sources of heterogeneity by performing the subgroup analyses described above as exploratory analyses, and by visual inspection of forest plots with consideration of individual trial characteristics.

For trials with multiple active intervention arms, in subgroup analyses where the intervention arms were stratified across the subgrouping strata, we used the single control group as the comparator in each subgroup.

#### Sensitivity analysis

We assessed the robustness of results for the primary outcomes of all-cause mortality, cardiovascular mortality and composite measures of MACE for sensitivity to risk of selection bias (excluding studies with a high risk of bias from random sequence generation) and attrition bias (excluding studies with a high or unclear risk of attrition bias). We also assessed the primary clinical outcomes for sensitivity to risk of performance bias (excluding those studies with a known lack of blinding of participants and clinicians).

We also assessed the primary outcome of mortality and any additional outcomes that showed evidence of a difference between trial arms for sensitivity to differences in the route of cell delivery, by excluding one trial that administered cells into the coronary artery (Nogueira 2009). This trial did not report the primary outcomes of cardiovascular mortality and composite measures of MACE.

Differences in methods of reporting for continuous outcomes across trials led us to combine mean change from baseline and

endpoint data for LVEF (see Data synthesis above). We have presented the results separately as well as in combination for clarity and to assess the sensitivity of the results to the method of reporting.

## RESULTS

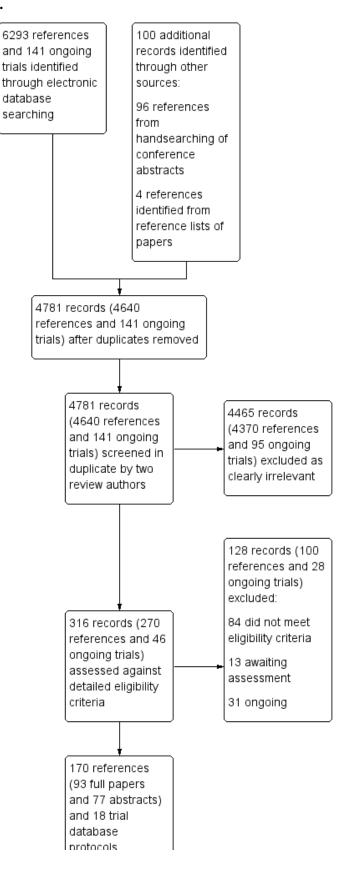

## **Description of studies**

Given that a wide variety of products and terms have been used in the comparator arms of the included trials, for ease of reference we will use the term 'control' throughout this review to refer to the comparator treatment arm.

We identified a total of 6434 records (6293 references and 141 ongoing trial records) from electronic searches of the CENTRAL, MEDLINE, EMBASE, SRI Transfusion Evidence Library, ClinicalTrials.gov, CDSR, DARE, CINAHL and Current Controlled Trials databases to March 2015. Additionally, handsearching of the American Heart Association Scientific Sessions, European Society of Cardiology Congress and World Congress of Cardiology annual conference proceedings from 2005 to January 2011 identified an additional 96 references, and we identified four further references from reference lists of reviews identified in the database search to give a total of 6534 citations. De-duplication and removal of all previously screened references by the SRI Information Specialist (CD) excluded 1753 references. Screening of the remaining 4781 records (4640 references and 141 ongoing trial records) by two review authors independently resulted in exclusion of 4465 records (4370 references and 95 ongoing trials), which were clearly irrelevant. Detailed assessment of the remaining 270 references and 46 ongoing trial records identified a total of 170 references (93 full papers and 77 abstracts) and 18 ongoing trial records, which described a total of 41 trials included in this review (see PRISMA study flow diagram in Figure 1).

## Figure 1. Study flow diagram.

## Figure 1. (Continued)

database protocols reporting 41 studies included in qualitative and quantitative data synthesis

#### Trials excluded from the review

We excluded 53 trials (described in 77 references and seven ongoing trial records) from the review following full-text eligibility assessment. In summary, the reasons for exclusion were as follows: six studies were not classified as AMI, 12 studies did not include a control arm, seven studies were non-randomised controlled trials, five studies infused G-CSF mobilised cells but did not administer G-CSF to the control arm, three studies mobilised cells by G-CSF but did not administer cells, five studies did not use autologous bone marrow stem cells, two studies were systematic reviews or metaanalyses, seven studies were commentaries or summaries, two studies were experimental, in two studies the outcomes were not relevant, one trial treated patients with acute myocardial infarction and 'old' myocardial infarction and the data were combined, and one trial had no relevant outcomes (see Characteristics of excluded studies).

#### Trials awaiting assessment and ongoing trials

Twelve trials described in 13 references appeared to meet the eligibility criteria for this review but reported insufficient information for the trials to be included (see Characteristics of studies awaiting classification). We await further publications on these trials. We identified 22 eligible ongoing trials described in 10 references and 21 ongoing trial database records (see Characteristics of ongoing studies). Current ongoing trials intend to recruit over 4750 participants in total and include the pan-European Phase III trial (the BAMI trial) (NCT01569178), which is aiming to recruit 3000 participants and is expected to be completed by May 2018. These ongoing trials will be included in future updates of the review.

#### Trials included in the review

We translated six trials from Chinese (Mandarin) to English (Huang 2006; Huang 2007; Jin 2008; Yao 2006; You 2008; Xiao 2012), and two from Russian to English (Karpov 2005; Zhukova 2009), prior to inclusion in this review, including one report of long-term follow-up, which we translated using Google Translate (https://translate.google.com/) for this update. An English version of a seventh Chinese paper was identified (Ruan 2005). Following careful cross-checking between the Chinese and English versions of the paper, which confirmed that both papers reported the same data from one trial, we used the English version of the paper within this review.

One trial included in the previous version of the review was previously referred to as Meyer 2006. This study is now referred to as Wollert 2004 in accordance with the first publication that reported results from this trial. Three trials included in the previous version of the review are now not included: two trials that used G-CSF to mobilise stem cells in the cell therapy arm did not give G-CSF to the control group and in view of the lack of this co-intervention in the control arm, these studies are now excluded (Kang 2006; Li 2006), and one trial published in abstract form only has been reclassified as awaiting classification as there were insufficient data provided for inclusion in any analyses (Fernandez-Pereira 2006).

Five trials had three-arm comparisons (Meluzin 2008; Nogueira 2009; Sürder 2013; Tendera 2009; Yao 2009), and one trial had a four-arm comparison (Quyyumi 2011). In Meluzin 2008, the two treatment arms compared different doses (low dose or high dose) of stem/progenitor cells administered. Likewise, in Quyyumi 2011, the three treatment arms compared low, moderate and high-dose administrations of selected CD34<sup>+</sup> cells. The two treatment arms in Yao 2009 compared a single dose (SD arm) of stem/progenitor cells at three to seven days post-AMI to a repeated dose (DD arm) - i.e. administration of stem/progenitor cells at both three to seven days and three months post-AMI. The two treatment arms in Nogueira 2009 compared intracoronary artery (arterial group – AG) delivery of stem/progenitor cells against intracoronary venous (venous group - VG) delivery of stem/progenitor cells. In Tendera 2009, the two treatment arms compared selected CD34<sup>+</sup> CXCR4<sup>+</sup> (selected -S) stem/progenitor cell administration versus non-selected (unselected - U) mononuclear cell administration. Sürder 2013 included two intervention groups comparing either five to seven days (early - E) or three to four weeks (late - L) cell administration. As stated in the Methods section, we pooled active intervention arms for the main analyses and compared this with the single control group.

We included a total of 41 trials; the number of participants included in each trial ranged from 11 to 204, and a total of 2732 participants (1564 cell therapy and 1168 controls) were included in the 41 comparisons of the review. The mean age of participants across all included trials ranged from 46.6 years (Jazi 2012) to 65.2 years (Piepoli 2010), with the mean age of participants between 50 and 60 years in all but seven trials (Table 1). All trials included predominantly male participants, with the per cent male ranging from 60.6% (Wang 2014) to 100% (Colombo 2011; Zhukova 2009); four trials reported female participants in one arm of the trial only (Gao 2013; Ge 2006; Penicka 2007; Ruan 2005) (Table 1). Ethnicity data were not available.

The trials included in the review were conducted in 17 countries, which included Belgium (Janssens 2006), Brazil (Angeli 2012; Nogueira 2009), China (Cao 2009; Chen 2004; Gao 2013; Ge 2006; Huang 2006; Huang 2007; Jin 2008; Ruan 2005; Wang 2014; Xiao 2012; Yao 2006; You 2008), Czech Republic (Meluzin 2008; Penicka 2007), Finland (Huikuri 2008), France (Roncalli 2010), Germany (Turan 2012; Wohrle 2010; Wollert 2004), Iran (Jazi 2012), Italy

(Colombo 2011; Piepoli 2010; Yao 2009), the Netherlands (Hirsch 2011), Norway (Lunde 2006), Poland (Grajek 2010; Plewka 2009; Tendera 2009), Russia (Karpov 2005; Zhukova 2009), South Korea (Lee 2014), Spain (Suarez de Lezo 2007), Switzerland (Sürder 2013), and the USA (Quyyumi 2011; Traverse 2010; Traverse 2011; Traverse 2012), and one trial was carried out in Germany and Switzerland (Schachinger 2006).

Twenty-three trials compared the active intervention (autologous bone marrow stem/progenitor cells) with no intervention and 18 trials compared the active intervention with placebo (Table 2). The majority of trials used PCI as the primary treatment for AMI. Thrombolytic therapy without PCI was used as the primary treatment in all patients in two trials (Huikuri 2008; You 2008), and some patients in two trials (Lee 2014; Zhukova 2009). Five trials used PCI in combination with thrombolytic therapy either in all patients (Jin 2008; Karpov 2005; Nogueira 2009; Sürder 2013), or in some patients (Wollert 2004) (Table 1). All trials maintained the patients with a standard set of drugs, including aspirin, clopidogrel, heparin,  $\beta$ -blockers, statins, angiotensin converting enzyme (ACE) inhibitors, nitrates and/or diuretics.

All but one trial, Zhukova 2009, reported short-term follow-up of less than 12 months with the majority reporting follow-up after six months; only three trials reported maximum follow-up of three months or less (Suarez de Lezo 2007; Xiao 2012; You 2008). No trial reported short-term follow-up of longer than six months. Twenty-five trials reported long-term follow-up, all but five of which included reporting of outcomes at 12 months. Fourteen trials reported follow-up of longer than 12 months, including 18 months (Wollert 2004), 24 months (Gao 2013; Hirsch 2011; Penicka 2007; Piepoli 2010; Plewka 2009; Schachinger 2006; Wohrle 2010; Zhukova 2009), 30 months (Yao 2006), 36 months (Lunde 2006; Wohrle 2010; Zhukova 2009), 48 months (Cao 2009), 60 months (Hirsch 2011; Schachinger 2006; Tendera 2009; Wollert 2004; Zhukova 2009), and a mean of 8.2 years (Karpov 2005). Longterm follow-up included both clinical outcomes and the surrogate endpoint of LVEF in all but four trials: one trial reported longterm follow-up of LVEF only (Janssens 2006), and three trials only reported clinical outcomes at long-term follow-up (Karpov 2005; Quyyumi 2011; Tendera 2009). We have analysed outcome data separately in this review; we have incorporated the maximum short-term or long-term time point from each trial into the analyses.

#### **Trial design characteristics - interventions**

Details of the individual trial interventions are given in the Characteristics of included studies tables and are summarised in Table 2.

Thirty-eight trials isolated the stem/progenitor cells by bone marrow aspiration and separated the mononuclear cell fraction by gradient centrifugation. Three trials failed to report the method of cell isolation or processing (Angeli 2012; Ge 2006; Ruan 2005).

Thirty-four trials administered unfractionated bone marrowderived mononuclear cells intracoronally via an inflated balloon catheter. This mononuclear cell population contains stem/ progenitor cells and other blood cells (Angeli 2012; Cao 2009; Chen 2004; Ge 2006; Grajek 2010; Hirsch 2011; Huang 2006; Huang 2007; Huikuri 2008; Janssens 2006; Jazi 2012; Jin 2008; Karpov 2005; Lunde 2006; Meluzin 2008; Nogueira 2009; Penicka 2007; Piepoli 2010; Plewka 2009; Roncalli 2010; Ruan 2005; Schachinger 2006; Suarez de Lezo 2007; Sürder 2013; Tendera 2009; Traverse 2010; Traverse 2011; Traverse 2012; Turan 2012; Wohrle 2010; Wollert 2004; Yao 2006; Yao 2009; Zhukova 2009). Three trials processed the mononuclear cell fraction using two-step immunomagnetic selection to isolate and administer a suspension containing a selected CD133+ cell population (Colombo 2011; Quyyumi 2011), or in one intervention arm of a three-arm trial, CD34<sup>+</sup>/CXCR4<sup>+</sup> cells (Tendera 2009). Five trials cultured cells to isolate mesenchymal stem cells (BM-MSC) (Gao 2013; Lee 2014; Wang 2014; Xiao 2012; You 2008).

One three-arm trial also administered unfractionated mononuclear cells intravenously to the coronary vein corresponding to the culprit coronary artery via a multipurpose guiding catheter (Nogueira 2009). Simultaneous total occlusion of the coronary vein was achieved via an inflated balloon catheter in the culprit coronary artery.

Cells were suspended in heparinised saline (Cao 2009; Chen 2004; Gao 2013; Huang 2006; Huang 2007; Jin 2008; Plewka 2009; Suarez de Lezo 2007; Wang 2014; Wollert 2004), heparinised saline with human serum albumin (Hirsch 2011), or autologous serum (Huikuri 2008; Janssens 2006), heparinised plasma (Lunde 2006; Yao 2009), saline solution and human serum albumin (Colombo 2011; Nogueira 2009; Traverse 2010; Traverse 2011; Traverse 2012), with 0.1% autologous erythrocytes (Wohrle 2010), heparinised phosphase buffered saline, autologous serum and human serum albumin (Quyyumi 2011), human serum albumin solution (Roncalli 2010), diluted autologous serum (Ruan 2005; Sürder 2013), autologous serum (Zhukova 2009), X-vivo medium and autologous serum (Schachinger 2006), or autologous plasma (Grajek 2010), M199 medium (Jazi 2012), phosphate buffered saline (Tendera 2009) with human serum albumin (Piepoli 2010), and lymphocyte isolation medium (Yao 2006).

Nine trials did not report details of the cell suspension (Angeli 2012; Ge 2006; Karpov 2005; Lee 2014; Meluzin 2008; Penicka 2007; Turan 2012; Xiao 2012; You 2008).

#### Timing of stem cell administration post-AMI

Nineteen trials delivered cells within seven days of AMI: six trials within the first 24 to 48 hours (Gao 2013; Ge 2006; Huang 2006; Huang 2007; Janssens 2006; Ruan 2005), and 13 trials at up to seven days after AMI (Cao 2009; Grajek 2010; Huikuri 2008; Nogueira 2009; Piepoli 2010; Schachinger 2006; Sürder 2013; Traverse 2012; Turan 2012; Wohrle 2010; Wollert 2004; Yao 2009; You 2008), including two trials with patients randomised to receive cells at either three days or seven days (Traverse 2012), or at five to seven days or three to four weeks (Sürder 2013) after AMI, and one trial in which some patients were randomised to receive a second dose at three months (Yao 2009).

In nine trials cells were administered within seven days in some patients although other patients received cells at up to eight days (Hirsch 2011; Lunde 2006), nine days (Angeli 2012; Meluzin 2008), 10 days (Traverse 2010), 11 days (Penicka 2007; Plewka 2009), and 12 days (Suarez de Lezo 2007; Tendera 2009) after AMI.

Fourteen trials administered cells at more than seven days after AMI (Chen 2004; Colombo 2011; Jazi 2012; Jin 2008; Karpov 2005; Lee 2014; Quyyumi 2011; Roncalli 2010; Sürder 2013; Traverse 2011; Wang 2014; Xiao 2012; You 2008; Zhukova 2009)

#### Comparator arm

Eighteen trials administered a placebo intervention to the control group (Angeli 2012; Cao 2009; Chen 2004; Ge 2006; Huang 2006; Huang 2007; Huikuri 2008; Janssens 2006; Ruan 2005; Schachinger 2006; Suarez de Lezo 2007; Traverse 2010; Traverse 2011; Traverse 2012; Wang 2014; Wohrle 2010; Xiao 2012; Yao 2009). In two trials the placebo medium was not reported (Angeli 2012; Ge 2006). Of the remaining 16 trials, all but one, Xiao 2012, used the same media used to re-suspend cells in the corresponding treatment arm to patients in the comparator arm (no cells). Xiao 2012 administered heparinised saline to the control group but did not report the resuspension medium used in the cell therapy group.

Twenty-three trials did not use a placebo intervention (Colombo 2011; Gao 2013; Grajek 2010; Hirsch 2011; Jazi 2012; Jin 2008; Karpov 2005; Lee 2014; Lunde 2006; Meluzin 2008; Nogueira 2009; Penicka 2007; Piepoli 2010; Plewka 2009; Quyyumi 2011; Roncalli 2010; Sürder 2013; Tendera 2009; Turan 2012; Wollert 2004; Yao 2006; You 2008; Zhukova 2009); no other interventions were reported other than optimal medical therapy.

#### Dose of stem/progenitor cells administered

The dose of cells administered varied considerably between trials; for simplicity we have grouped trials according to the mean dose:  $10^6$  cells;  $10^7$  cells;  $10^8$  cells;  $10^9$  cells and  $10^{10}$  cells.

Three trials administered magnetically selected cells at a dose of 10<sup>6</sup> CD133+ cells (Colombo 2011), 10<sup>6</sup> CD34<sup>+</sup> CXCR4<sup>+</sup> cells (Tendera 2009), and 10<sup>6</sup> or 10<sup>7</sup> CD34<sup>+</sup> cells (three randomised cell dose groups) (Quyyumi 2011). In five trials that administered mesenchymal stem cells, cells were administered at a dose of 10<sup>6</sup> (Gao 2013), 10<sup>7</sup> (Lee 2014; Wang 2014; You 2008), and 10<sup>8</sup> (Xiao 2012).

Bone marrow mononuclear cells were administered to patients at a dose of up to 10<sup>7</sup> (Ge 2006; Jin 2008; Karpov 2005; Lunde 2006; Nogueira 2009; Roncalli 2010; Traverse 2010; Zhukova 2009), 10<sup>8</sup> (Angeli 2012; Cao 2009; Grajek 2010; Hirsch 2011; Huang 2006; Huang 2007; Huikuri 2008; Janssens 2006; Piepoli 2010; Plewka 2009; Schachinger 2006; Suarez de Lezo 2007; Sürder 2013; Tendera 2009; Traverse 2011; Traverse 2012; Wohrle 2010; Yao 2006; Yao 2009), 10<sup>9</sup> (Jazi 2012; Penicka 2007; Wollert 2004), and 10<sup>10</sup> (Chen 2004). One trial compared two doses of BMMNC: 10<sup>6</sup> or 10<sup>8</sup> (Meluzin 2008). Only two trials did not give details of the cell dose administered to patients (Ruan 2005; Turan 2012).

## **Risk of bias in included studies**

A description of the risk of bias for individual studies is given in the Characteristics of included studies tables. A summary of the risk of selection bias, performance and detection bias, attrition bias, reporting bias and other potential sources of bias including baseline imbalances between trial arms, publication bias and study funding is given below.

## Allocation

Twenty trials provided details as to the generation of the randomisation sequence (Cao 2009; Colombo 2011; Gao 2013; Ge 2006; Grajek 2010; Hirsch 2011; Huikuri 2008; Janssens 2006; Lunde 2006; Nogueira 2009; Piepoli 2010; Roncalli 2010; Schachinger 2006; Sürder 2013; Traverse 2010; Traverse 2011; Traverse 2012; Wollert

2004; Yao 2009; You 2008). These methods included: sequential numbers (Gao 2013; Ge 2006; Wollert 2004), "uneven vs. even numbers" (Piepoli 2010), a randomisation table (You 2008), a randomisation list generated in permuted blocks of 10, stratified according to centre (Lunde 2006), a randomisation list generated in permuted blocks of six (Grajek 2010), a randomisation list generated in permuted blocks of undefined size (Colombo 2011), a randomisation list generated in permuted blocks with variable block sizes (Huikuri 2008), a randomisation list generated according to infarct size (Nogueira 2009), a permuted-block randomisation list stratified according to centre, diabetes status and time to PCI after the onset of AMI (Roncalli 2010), an interactive webbased randomisation session using randomly selected block sizes of six or nine, stratified by centre (Traverse 2011), a permutedblock randomisation list stratified according to site (Hirsch 2011), computer-generated random lists (Cao 2009; Janssens 2006; Schachinger 2006; Yao 2009; Traverse 2012), and a randomisation algorithm developed by a biostatistician (Traverse 2010). Four trials reported using sealed envelopes (Ge 2006; Nogueira 2009; Sürder 2013; Wollert 2004), and two trials generated randomisation lists at a site external to the trial site (Schachinger 2006; Wollert 2004). We defined 19 trials as having a low risk of selection bias due to random sequence generation; we considered one trial that allocated treatment using even versus uneven numbers to have a high risk of selection bias (Piepoli 2010); we also deemed this trial to have a high risk of selection bias due to insufficient allocation concealment. We also deemed 14 trials to have used an appropriate method of allocation concealment (Cao 2009; Colombo 2011; Ge 2006; Huikuri 2008; Janssens 2006; Lunde 2006; Nogueira 2009; Roncalli 2010; Schachinger 2006; Sürder 2013; Traverse 2010; Traverse 2011; Wollert 2004; Yao 2009). One trial reported that the randomisation scheme was not blinded and we therefore considered it to have a high risk of selection bias due to lack of allocation concealment (Traverse 2012). Allocation concealment was unclear in the remaining four trials (Gao 2013; Grajek 2010; Hirsch 2011; You 2008).

We defined the generation of the randomisation sequence as unclear in the 'Risk of bias' tables in 13 trials in which no description was given as to what methods were used to generate the random sequence (Angeli 2012; Jazi 2012; Karpov 2005; Lee 2014; Meluzin 2008; Penicka 2007; Plewka 2009; Quyyumi 2011; Suarez de Lezo 2007; Tendera 2009; Turan 2012; Wohrle 2010; Zhukova 2009). The method of generation of randomisation sequence was also not reported in eight Chinese trials, which we deemed to have a high risk of bias (Chen 2004; Huang 2006; Huang 2007; Jin 2008; Ruan 2005; Wang 2014; Xiao 2012; Yao 2006).

## Blinding

In nine trials, the control group underwent bone marrow aspiration and were given a placebo injection. These trials also reported blinding of outcome assessors or described the trial as "doubleblind" and we therefore considered them to have a low risk of performance and detection bias (Chen 2004; Ge 2006; Huikuri 2008; Janssens 2006; Schachinger 2006; Traverse 2010; Traverse 2011; Traverse 2012; Wohrle 2010). In a further eight trials in which a placebo injection was also administered (Angeli 2012; Cao 2009; Huang 2006; Huang 2007; Ruan 2005; Suarez de Lezo 2007; Wang 2014; Xiao 2012), bone marrow aspiration in the control group was either not undertaken (Cao 2009; Suarez de Lezo 2007; Xiao 2012), or was not reported (Angeli 2012; Huang 2006; Huang 2007; Ruan

2005; Wang 2014); in these eight trials the risk of performance bias was unclear. Only four of these trials reported blinding of outcome assessors (Cao 2009; Ruan 2005; Suarez de Lezo 2007; Xiao 2012); blinding of outcome assessors was otherwise not reported (Angeli 2012; Huang 2006; Huang 2007; Wang 2014).

In one other trial, although the control group received a placebo injection, only the active intervention groups underwent bone marrow aspiration (Yao 2009). Furthermore, the active treatment groups were recalled for a second infusion of cells or placebo whereas the control group was not, and we therefore deemed these trials to have a high risk of performance bias.

Participants were not blinded to treatment in 23 trials in which no placebo infusion was administered (Colombo 2011; Gao 2013; Grajek 2010; Hirsch 2011; Jazi 2012; Jin 2008; Karpov 2005; Lee 2014; Lunde 2006; Meluzin 2008; Nogueira 2009; Penicka 2007; Piepoli 2010; Plewka 2009; Quyyumi 2011; Roncalli 2010; Sürder 2013; Tendera 2009; Turan 2012; Wollert 2004; Yao 2006; You 2008; Zhukova 2009), which we considered to have a high risk of performance bias. Outcome assessors were reported to be blinded in all trials except five: one trial stated that study processes were not blinded (Hirsch 2011), and in four trials blinding of outcome assessors was not reported (Jazi 2012; Karpov 2005; Yao 2006; You 2008).

#### Incomplete outcome data

Eighteen trials had a low risk of attrition bias as either all randomised participants were included in the analysis of all outcome data or all participant withdrawals were due to death or other major clinical adverse events (Angeli 2012; Cao 2009; Chen 2004; Colombo 2011; Ge 2006; Grajek 2010; Huang 2006; Huang 2007; Jin 2008; Nogueira 2009; Penicka 2007; Piepoli 2010; Ruan 2005; Suarez de Lezo 2007; Traverse 2010; Turan 2012; You 2008; Zhukova 2009). We also deemed a further 13 trials to have a low risk of attrition bias as withdrawals were low and balanced between treatment arms (Gao 2013; Hirsch 2011; Huikuri 2008; Janssens 2006; Lunde 2006; Roncalli 2010; Schachinger 2006; Traverse 2011; Traverse 2012; Wang 2014; Wohrle 2010; Wollert 2004; Yao 2009).

In two trials the risk of attrition bias was unclear as the number of participants randomised to each treatment arm was not reported (Jazi 2012; Meluzin 2008). The number of withdrawals was unbalanced in a further three trials (Quyyumi 2011; Xiao 2012; Yao 2006), although reasons for participant withdrawal were reported; these trials were considered to have an unclear risk of bias.

Five trials had a high risk of attrition bias. In three trials the number of withdrawals was high or unbalanced between treatment arms (Lee 2014; Sürder 2013; Tendera 2009), and in two trials there was incomplete participant overlap across multiple trial reports (Karpov 2005; Plewka 2009).

In the analysis of clinical outcomes, 24 trials included all randomised participants and 11 included over 90% of randomised

participants. Four trials included between 80% and 90% (Grajek 2010; Meluzin 2008; Sürder 2013; Yao 2009). All four trials explained the reasons for participant withdrawal or exclusion although in one trial these did not fully account for discrepancies in the number of participants included in individual analyses (Sürder 2013). One trial only included 72.5% of randomised participants in the analysis of clinical outcomes (Lee 2014); reasons included protocol violation, loss to follow-up and the opinion of the investigator. In one trial it was unclear how many participants were randomised to treatment (Jazi 2012).

In the analysis of LVEF, all trials that reported LVEF measured by echocardiography, SPECT, left ventricular angiography or radionuclide ventriculography included over 80% of randomised participants in the analysis of this outcome, with the exception of two trials, which analysed 72.5% (Lee 2014) and 60% (Plewka 2009) of randomised participants. A higher rate of withdrawals was observed in the analysis of LVEF measured by MRI in which five trials analysed less than 80% of randomised participants: 79.2% (Traverse 2012), 67.7% (Quyyumi 2011), 763.6% (Zhukova 2009), 58.5% (Tendera 2009) and 28.9% (Schachinger 2006), although it should be noted that not all participants are willing or able to undergo MRI leading to an expected reduction in the number of patients analysed.

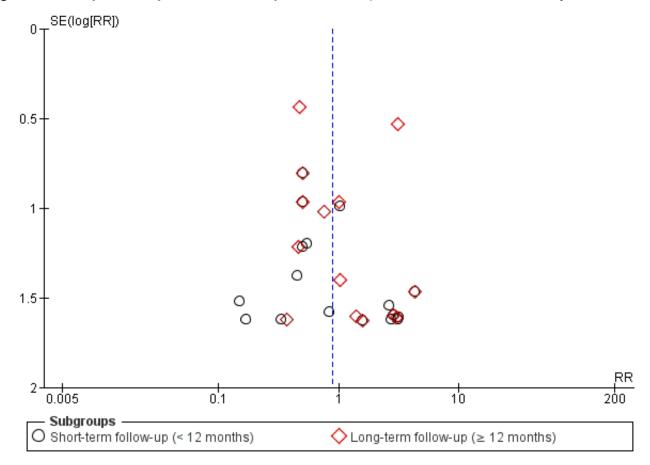

One trial was terminated prematurely after enrolment of the first 27 participants (Penicka 2007). The trial was reported as being terminated early "due to the unexpected occurrence of serious complications in the BMSC group and no incremental functional effects of BMSC as compared with control patients". Fourteen of the 17 participants randomised to the BMSC arm provided scientific outcome data at four and 12-month follow-up assessments. All participants in the control arm were included in the final analysis in this trial.

## Selective reporting

Out of 41 trials (with 2732 participants) only 18 trials (1567 participants) reported a published protocol (see Characteristics of included studies) and in this sub-sample there was no evidence of selective reporting. However, given that the majority of trials did not report details of their protocol it is difficult to ascertain whether these trials are at low risk of selective reporting. We considered one trial to have a high risk of reporting bias as the authors failed to report quality of life and cost-effectiveness despite these outcomes being described in their trial protocol (Nogueira 2009).

We identified no obvious asymmetry from a funnel plot for mortality (using the maximum duration of follow-up for all trials that reported mortality) (Figure 2). In a regression test for asymmetry (Egger's test) at short-term follow-up the model intercept was 0.15 (P value = 0.01), suggesting that larger rather than smaller trials may be associated with a larger treatment effect. At long-term follow-up, the test for asymmetry was not significant (P value = 0.06) and there was no evidence of publication bias.

## Figure 2. Funnel plot of comparison: 1 Cells compared to no cells, outcome: 1.1 All-cause mortality.

## Other potential sources of bias

Four trials reported statistically significant baseline differences in participant characteristics between trial arms: Sürder 2013 reported a lower percentage of smokers in the late treatment arm than controls (40.3% versus 62.7%; P value = 0.01) and a lower median baseline LVEF (median 35.6% versus 39.6%, P value = 0.03) in the cell therapy group compared with controls; Traverse 2011 reported a higher mean heart rate on initial presentation to the emergency department in the placebo group than the cell therapy group (90.3% versus 77.5%, P value = 0.01); Traverse 2012 observed high peak creatine kinase and troponin levels in the bone marrow cell (BMC) group randomised to day seven and a lack of diabetes in the placebo group randomised to day seven (P values not reported); and in Wohrle 2010 there was a significant baseline imbalance in the proportion of males (62% in the placebo group compared with 90% in the cell therapy group, P value = 0.04). These baseline differences are more likely to be a source of diversity than study bias.

Ten trials did not report the source of funding (Angeli 2012; Chen 2004; Huang 2006; Jazi 2012; Karpov 2005; Ruan 2005; Suarez de Lezo 2007; Wang 2014; Wohrle 2010; Zhukova 2009). Of 31 trials that reported funding and support, all but two trials, Lee 2014 and Schachinger 2006, received research grant funding from universities, charities or governmental agencies (see Characteristics of included studies). Schachinger 2006 received a research grant from Guidant (Guidant Corporation, part of Boston Scientific, which designs and manufactures cardiovascular medical products), as well as support from Eli Lilly (Eli Lilly is a global pharmaceutical company) and Lee 2014 was funded by PCB-Pharmicell Company Limited, Seongnam, South Korea (a biotechnology company focusing on the development and commercialisation of stem cell therapeutics). Five trials were commercially funded in part: Huikuri 2008 received a research grant from Boston Scientific Sverige AB (a global pharmaceutical company); Grajek 2010 received a research grant from Servier Polska (a global pharmaceutical company); Hirsch 2011 received "unrestricted grants" from Biotronik (Biotronik designs and manufactures cardiovascular medical products), Boston Scientific, Guerbet (Guerbet designs and manufactures medical imaging products including contrast agents), Medtronic (Medtronic designs and manufactures cardiovascular medical products), Novartis, Pfizer and Sanofi-Aventis (all global pharmaceutical companies); Quyyumi 2011 was funded by Amorcyte Inc (Amorcyte Inc. develops cell therapy products to treat cardiovascular disease); and in Nogueira 2009 cell preparation and characterisation was carried out by Exellion Biomedical Services S/A.

A total of 17 patients from eight trials randomised to cell therapy did not receive treatment as randomised but were included in the analysis (Hirsch 2011; Lunde 2006; Meluzin 2008; Nogueira 2009; Penicka 2007; Roncalli 2010; Traverse 2011; Yao 2009), as well as three patients randomised to a placebo arm who did not receive the placebo medium (Schachinger 2006); in all cases this was

due to adverse clinical events, which precluded cell or placebo administration.

# **Effects of interventions**

See: Summary of findings for the main comparison Cells compared to no cells for acute myocardial infarction (AMI)

An overview of results for the primary outcomes of all-cause mortality, cardiovascular mortality and composite measures of major adverse cardiac events (MACE) are given in Summary of findings for the main comparison. A summary of outcome reporting is given in Table 3, together with the number and proportion of randomised participants from all trials included in the analysis of each outcome at short-term and long-term follow-up. The number of events in each trial arm observed at the longest reported follow-up of clinical (dichotomous) outcomes of all-cause mortality, cardiovascular mortality, a composite measure of death, reinfarction and re-hospitalisation for heart failure, reinfarction and target vessel revascularisation is given in Table 4.

## **Primary outcomes**

## All-cause mortality

Seventeen trials reported incidences of mortality in the shortterm follow-up period of less than 12 months from cell therapy (Gao 2013; Huikuri 2008; Janssens 2006; Nogueira 2009; Penicka 2007; Piepoli 2010; Plewka 2009; Quyyumi 2011; Roncalli 2010; Schachinger 2006; Sürder 2013; Tendera 2009; Traverse 2011; Traverse 2012; Wang 2014; Wohrle 2010; Zhukova 2009). All incidences of mortality in the short-term follow-up period occurred within six months of cell therapy. A further 17 trials reported that no deaths occurred during short-term follow-up (see Table 3).

In trials that reported long-term follow-up, 14 reported incidences of mortality (Cao 2009; Gao 2013; Grajek 2010; Hirsch 2011; Karpov 2005; Lunde 2006; Penicka 2007; Piepoli 2010; Plewka 2009; Quyyumi 2011; Schachinger 2006; Traverse 2012; Wollert 2004; Zhukova 2009), with nine trials reporting no deaths during longterm follow-up. The duration of long-term follow-up ranged from 12 months (Grajek 2010; Piepoli 2010; Quyyumi 2011; Traverse 2012), 24 months (Gao 2013; Penicka 2007; Plewka 2009), 36 months (Lunde 2006; Zhukova 2009) and 48 months (Cao 2009), to 60 months (Hirsch 2011; Schachinger 2006; Wollert 2004), and in one trial there was a mean follow-up of 8.2 (standard deviation (SD) 0.72) years (Karpov 2005).

The mortality incidence rate was low in all trials. Overall, there was no evidence for a difference in the risk of mortality between patients who received cell therapy and those who received no cells at short-term (21/836 versus 15/529; risk ratio (RR) 0.80, 95% confidence interval (CI) 0.43 to 1.49; 1365 participants; 17 studies) or long-term follow-up (34/538 versus 32/458; RR 0.93, 95% CI 0.58 to 1.50; 996 participants; 14 studies) with no evidence of heterogeneity ( $I^2 = 0\%$  in both analyses) (Analysis 1.1).

Sensitivity analyses did not affect the results for mortality. Exclusion of the trial that administered cells via the coronary artery,

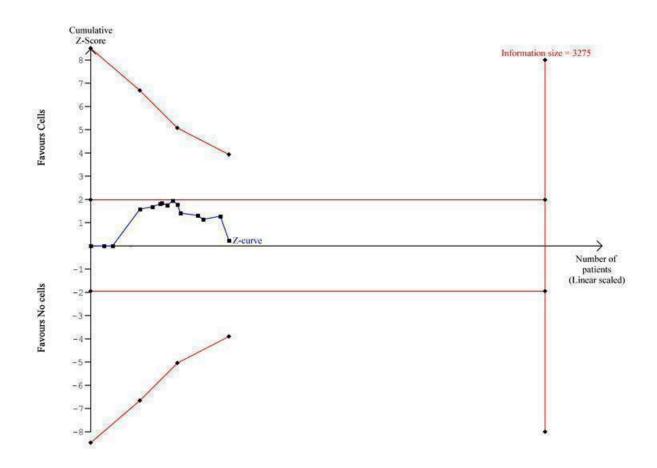

Nogueira 2009, did not affect short-term mortality results (20/812 versus 15/523; RR 0.80, 95% CI 0.42 to 1.51; 1335 participants; 16 studies) (Analysis 2.1). Only one trial included in the analysis of short-term follow-up had a high risk of selection bias due to lack of appropriate randomisation sequence generation (Wang 2014); the difference in risk of mortality between groups when we excluded this trial was negligible (20/808 versus 13/499; RR 0.83, 95% CI 0.43 to 1.57; 1307 participants; 16 studies) (Analysis 3.1). No trials reporting long-term follow-up had a high risk of selection bias due to randomisation methods. When we excluded trials with a high or unclear risk of attrition bias, there remained no evidence for a difference in all-cause mortality at either short-term (14/505 versus 12/394; RR 0.78, 95% CI 0.38 to 1.61; 899 participants; 13 studies) or long-term follow-up (21/456 versus 26/391; RR 0.67, 95% CI 0.38 to 1.17; 847 participants; 11 studies) (Analysis 4.1; Analysis 4.2). Similarly, exclusion of trials with a high risk of performance bias due to lack of blinding revealed no evidence for differences in the risk of mortality at either short-term (6/376 versus 8/293; RR 0.60, 95% CI 0.23 to 1.56; 669 participants; eight studies) or long-term follow-up (8/220 versus 16/186; RR 0.50, 95% CI 0.22 to 1.10; 406 participants; three studies) (Analysis 5.1; Analysis 5.2).

Subgroup analysis of mortality measured at short-term followup revealed no differences between trials grouped according to baseline left ventricular ejection fraction (LVEF) as measured by magnetic resonance imaging (MRI) (Analysis 6.1), cell type (Analysis 7.1), cell dose (Analysis 8.1), timing of cell infusion (Analysis 9.1), or use of heparinised cell solution (Analysis 10.1). However, stratification of trials by cell dose revealed a significant difference in the effect of cells on long-term mortality (test for subgroup differences, P value = 0.02) (Analysis 8.2), with a reduced risk of mortality in patients who received >  $10^8$  and  $\leq 10^9$  cells (14/371) versus 24/297; RR 0.52, 95% CI 0.28 to 0.97; 668 participants; seven studies), whereas there was no evidence for a difference in the risk of long-term mortality associated with a lower dose ( $\leq 10^8$  cells) (15/120 versus 6/121; RR 2.20, 95% CI 0.97 to 4.95; 241 participants; five studies) (Analysis 8.2). Only two trials administered > 10<sup>9</sup> cells; there was no difference in the risk of mortality between treatment groups from meta-analysis of these two trials (5/47 versus 2/40; RR 1.56, 95% CI 0.32 to 7.55; 87 participants; two studies). There was no difference in the risk of long-term mortality associated with cell therapy associated with either baseline LVEF (Analysis 6.2), cell type (Analysis 7.2), timing of cell administration (Analysis 9.2), or use of heparinised cell solution (Analysis 10.2).

In trial sequential analysis of all-cause mortality at longterm follow-up, the cumulative Z-curve did not cross the conventional thresholds or trial sequential monitoring boundaries for significance (see Figure 3). The required information size, based on a random-effects model and a relative risk reduction of 35%, a mean effect size equivalent to that associated with revascularisation by percutaneous coronary intervention (PCI) (Hartwell 2005), was 3275, suggesting that the current metaanalysis is considerably underpowered to detect a reduction in relative risk of 35% or lower. Smaller relative risks would result in a considerably greater information size.

#### Cardiovascular mortality

Incidence of cardiovascular mortality was reported in seven trials at short-term follow-up (Gao 2013; Huikuri 2008; Penicka 2007; Piepoli 2010; Plewka 2009; Quyyumi 2011; Zhukova 2009), and nine trials at long-term follow-up (Gao 2013; Karpov 2005; Penicka 2007; Piepoli 2010; Plewka 2009; Quyyumi 2011; Schachinger 2006; Wollert 2004; Zhukova 2009). There was no evidence for a difference in the risk of cardiovascular mortality at either short-term (7/161 versus 7/129; RR 0.72, 95% CI 0.28 to 1.82; 290 participants; seven studies) or at long-term follow-up (23/277 versus 18/250; RR 1.04, 95% CI 0.54 to 1.99; 527 participants; nine studies) (Analysis 1.2).

None of the trials that reported cardiovascular mortality had a high risk of selection bias. The lack of evidence for a difference in the risk of cardiovascular mortality remained when we excluded trials with a high or unclear risk of attrition bias at both short-term (4/105 versus 5/94; RR 0.69, 95% CI 0.22 to 2.14; 199 participants; five studies) (Analysis 4.3) and long-term follow-up (12/195 versus 14/183; RR 0.71, 95% CI 0.34 to 1.50; 378 participants; six studies) (Analysis 4.4). The number of appropriately blinded trials precluded sensitivity analysis for performance bias.

Trial sequential analysis of cardiovascular mortality at long-term follow-up found an information size of 3064 participants based on a relative risk reduction of 35%, demonstrating that the current meta-analysis is considerably underpowered to detect an effect of this magnitude.

#### Composite measures of major adverse cardiac events (MACE)

Composite measures of MACE were reported in 10 trials (Gao 2013; Hirsch 2011; Penicka 2007; Plewka 2009; Schachinger 2006; Sürder 2013; Traverse 2012; Wohrle 2010; Wollert 2004; Xiao 2012). Six trials defined composite MACE as death, reinfarction or re-hospitalisation for heart failure (Gao 2013; Hirsch 2011; Penicka 2007; Schachinger 2006; Wohrle 2010; Wollert 2004). Other definitions of composite MACE were as follows: death, reinfarction or target vessel revascularisation (Hirsch 2011; Schachinger 2006), death, reinfarction, re-hospitalisation for heart failure or revascularisation (Plewka 2009; Sürder 2013), death, reinfarction, re-hospitalisation for heart failure, revascularisation, implantable cardioverter-defibrillator (ICD) implantation or stroke (Traverse 2012), and death, reinfarction, re-hospitalisation for heart failure, stroke or arrhythmia (Gao 2013). One trial did not define the composite measure of MACE (Xiao 2012). Analysis was restricted to composite death, reinfarction or re-hospitalisation for heart failure due to the lack of data from alternative measures. Of note, one study with mortality data reported at five-year followup only reported two-year follow-up data for composite MACE, the incidence of which is lower than the five-year mortality rate (Schachinger 2006).

There was no evidence for a reduction in the risk of composite death, reinfarction or re-hospitalisation for heart failure associated with cell therapy at either short-term (5/198 versus 12/181; RR 0.36, 95% CI 0.12 to 1.14; 379 participants; three studies) or long-term follow-up (24/262 versus 33/235; RR 0.63, 95% CI 0.36 to 1.10; 497 participants; six studies) with low or negligible heterogeneity in both analyses ( $I^2 = 0\%$ ;  $I^2 = 12\%$  respectively) (Analysis 1.3). The limited number of trials that reported other composite measures of MACE at short-term or long-term follow-up prevented formal analysis of these outcomes.

We did not perform sensitivity analysis as no trials that reported composite measures of MACE had a high risk of selection bias or a high or unclear risk of attrition bias, and the number of appropriately blinded trials precluded sensitivity analysis for performance bias.

Trial sequential analysis of cardiovascular mortality at long-term follow-up showed that based on a relative risk reduction of 35%, 1572 participants would be required, demonstrating that the current meta-analysis is considerably underpowered to detect such a difference in the risk of composite MACE between treatment groups.

#### Periprocedural adverse events

Twenty-seven trials reported periprocedural adverse events as an outcome, six of which reported no periprocedural adverse events (Colombo 2011; Ge 2006; Karpov 2005; Traverse 2010; Turan 2012; Wollert 2004) (see Table 5 for details). Adverse events associated with bone marrow aspiration were rare; only one trial reported a serious adverse event at the time of bone marrow harvest (one patient experienced a stent thrombosis with reinfarction which occurred immediately after the procedure) (Penicka 2007); a second trial reported three patients with mild self limiting vasovagal reactions during bone marrow aspiration (Huikuri 2008). No other adverse events associated with bone marrow harvest were reported. Three deaths were reported in patients randomised to cell therapy prior to cell infusion (one patient died due to subarachnoid haemorrhage (Traverse 2012) and in two patients the cause of death was not reported (Sürder 2013)), and three patients died soon after cell therapy was administered (one at three days after cell therapy due to suspected acute in-stent thrombosis (Gao 2013), one from ventricular fibrillation attributed to recurrent myocardial infarction from stent thrombosis preceding cell infusion (Quyyumi 2011), and one with cause of death not reported (Schachinger 2006)). Other serious periprocedural adverse events observed in patients who received cell therapy included one transient acute heart failure (Cao 2009), one acute coronary occlusion during cell injection (Gao 2013), one patient with a small thrombus in the infarct-related artery diagnosed immediately after cell transplantation (Meluzin 2008), one patient with sub-acute stent thrombosis (Huikuri 2008), four patients with periprocedural myocardial infarction (Lee 2014; Schachinger 2006), one transient ischaemic attack (Roncalli 2010), and one postprocedural arteriovenous fistula of the femoral artery (Tendera 2009). In summary, serious periprocedural adverse events were rare and unlikely to be associated with treatment.

#### Secondary outcomes

#### Reinfarction

Seventeen trials reported incidences of reinfarction in the shortterm follow-up period of less than 12 months from stem cell therapy (Gao 2013; Grajek 2010; Hirsch 2011; Huikuri 2008; Karpov 2005; Lee 2014; Lunde 2006; Meluzin 2008; Penicka 2007; Plewka 2009; Sürder 2013; Tendera 2009; Traverse 2011; Traverse 2012; Wollert 2004; Yao 2006; Yao 2009). A further five trials reported that no incidences of reinfarction occurred during short-term follow-up (see Table 3).

Incidences of reinfarction occurred in 14 trials at long-term followup (Gao 2013; Hirsch 2011; Karpov 2005; Lunde 2006; Meluzin 2008; Penicka 2007; Plewka 2009; Schachinger 2006; Traverse 2010; Traverse 2012; Wollert 2004; Yao 2006; Yao 2009; Zhukova 2009); one further trial reported no incidences of reinfarction (Cao 2009).

There was no evidence for a difference in the risk of reinfarction between treatment groups at either short-term (16/927 versus 16/594; RR 0.66, 95% CI 0.33 to 1.30; 1521 participants; 17 studies) or long-term follow-up (20/624 versus 25/492; RR 0.64, 95% CI 0.36 to 1.12; 1116 participants; 14 studies) with no evidence of heterogeneity ( $I^2 = 0\%$  for both analyses) (Analysis 1.4).

Four patients were reported to have died following reinfarction. One death occurred due to reinfarction as the cells were harvested; the patient died from sepsis and acute respiratory distress syndrome (ARDS) two weeks following repeat PCI and coronary artery bypass graft (CABG) (Penicka 2007). Another death occurred soon after cell infusion from ventricular fibrillation that was attributed to recurrent myocardial infarction from stent thrombosis preceding cell infusion; in this four-armed trial it was not reported in which trial arm this patient had been randomised (Quyyumi 2011). Two other deaths due to reinfarction were reported at threemonth (Zhukova 2009) and 12-month (Schachinger 2006) follow-up respectively.

## Arrhythmias

Twenty-one trials reported arrhythmia as an outcome, although two trials reported summary results only (Piepoli 2010; Yao 2009), and in a further 11 trials arrhythmias were not observed during follow-up (see Table 3). In eight trials that reported incidences of arrhythmias, arrhythmia was defined as incidences of supraventricular arrhythmia (Janssens 2006), supraventricular tachycardia (Zhukova 2009), documented ventricular arrhythmia (Schachinger 2006), ventricular fibrillation (Hirsch 2011), sustained ventricular arrhythmia (Lunde 2006), repetitive ventricular arrhythmia (Colombo 2011), malignant arrhythmia (Xiao 2012) and arrhythmia (unspecified) (Roncalli 2010).

Five trials reported incidences of arrhythmias at short-term followup (Hirsch 2011; Janssens 2006; Roncalli 2010; Schachinger 2006; Xiao 2012). There was no evidence for a difference in the risk of arrhythmias at short-term follow-up between patients who received cell therapy and those who did not (15/264 versus 15/261; RR 1.00, 95% CI 0.51 to 1.98; 525 participants; five studies). Similarly, in five trials that reported incidences of arrhythmia at long-term follow-up (Colombo 2011; Hirsch 2011; Lunde 2006; Schachinger 2006; Zhukova 2009), there was no difference in the risk of arrhythmias between treatment arms (11/231 versus 7/226; RR 1.39, 95% CI 0.58 to 3.37; 457 participants; five studies) (Analysis 1.7).

Stem cell treatment for acute myocardial infarction (Review)

## Restenosis

Fifteen trials reported incidences of restenosis during follow-up (Cao 2009; Grajek 2010; Huikuri 2008; Janssens 2006; Lunde 2006; Meluzin 2008; Nogueira 2009; Penicka 2007; Piepoli 2010; Quyyumi 2011; Roncalli 2010; Traverse 2010; Wohrle 2010; Wollert 2004; Yao 2006). However, one trial did not report restenosis as an outcome in the control arm of the trial (Nogueira 2009), and one trial reported results descriptively (Huikuri 2008). One trial with long-term follow-up data did not report individual group sample sizes (Meluzin 2008). Two trials reported no incidences of restenosis during follow-up (Jazi 2012; Suarez de Lezo 2007).

Restenosis at short-term follow-up was reported in eight trials (Grajek 2010; Janssens 2006; Lunde 2006; Meluzin 2008; Roncalli 2010; Wohrle 2010; Wollert 2004; Yao 2006). The rate of restenosis at short-term follow-up was similar in patients who received cell therapy and in the control group (42/353 versus 34/288; RR 0.95, 95% CI 0.63 to 1.43; 641 participants; eight studies). There was also no evidence for a difference in the risk of restenosis at long-term follow-up in five trials (Cao 2009; Penicka 2007; Piepoli 2010; Traverse 2010; Yao 2006) (10/213 versus 14/182; RR 0.58, 95% CI 0.27 to 1.25; 395 participants; six studies) (Analysis 1.8).

## Target vessel revascularisation

The requirement for percutaneous coronary intervention in the infarct-related vessel during follow-up and after the therapy procedure was determined as target vessel revascularisation. Eleven trials reported incidences of target vessel revascularisation in one or both trial arms (Cao 2009; Grajek 2010; Hirsch 2011; Lunde 2006; Quyyumi 2011; Schachinger 2006; Tendera 2009; Traverse 2010; Traverse 2011; Traverse 2012; Wollert 2004). Four trials reported no incidences of target vessel revascularisation during follow-up (Janssens 2006; Lee 2014; Suarez de Lezo 2007; Wohrle 2010).

At short-term follow-up, there was no evidence for a difference in the risk of target vessel revascularisation between patients who received cell therapy and those who did not (50/497 versus 40/292; RR 0.70, 95% CI 0.47 to 1.06; 789 participants; six studies). There was also no difference in the risk of target vessel revascularisation between treatment arms at long-term follow-up (62/408 versus 62/350; RR 0.96, 95% CI 0.67 to 1.37; 758 participants; eight studies) (Analysis 1.6).

Of note, the incidence of restenosis seems to be lower than the incidence of target vessel revascularisation, and this may look like a discrepancy as the latter is a consequence of the former. However, the trials included in these two meta-analyses differ, as not all trials reported both outcomes. Three trials reported both restenosis and target vessel revascularisation (Cao 2009; Quyyumi 2011; Traverse 2010), and the numbers were the same for both outcomes.

## Re-hospitalisation for heart failure

Incidences of hospital readmission for heart failure were reported in 13 trials at short-term follow-up (Colombo 2011; Hirsch 2011; Huikuri 2008; Lunde 2006; Meluzin 2008; Penicka 2007; Roncalli 2010; Schachinger 2006; Sürder 2013; Traverse 2011; Traverse 2012; Wohrle 2010; Wollert 2004), and 11 trials at long-term followup (Colombo 2011; Gao 2013; Hirsch 2011; Lunde 2006; Meluzin 2008; Penicka 2007; Plewka 2009; Quyyumi 2011; Schachinger 2006; Traverse 2012; Wollert 2004). However, in one trial reporting discrepancies between publications could not be resolved with the study authors and therefore we omitted this study from the analysis at long-term follow-up (Colombo 2011).

At short-term follow-up there was no evidence for a difference in the risk of re-hospitalisation for heart failure between patients who received cell therapy and those who did not (17/684 versus 15/510; RR 0.81, 95% CI 0.40 to 1.62; 1194 participants; 13 studies). However, at long-term follow-up of 12 months or longer, there was marginally significant evidence for a difference between treatment groups in favour of cell therapy (18/459 versus 27/366; RR 0.55, 95% CI 0.30 to 1.00; 825 participants; 10 studies) (Analysis 1.5).

## Quality of life and performance status

Quality of life measures were reported in six trials (Jin 2008; Karpov 2005; Lunde 2006; Penicka 2007; Roncalli 2010; You 2008). Three trials used the Minnesota Living with Heart Failure Questionnaire (MLHFQ) (Jin 2008; Karpov 2005; Roncalli 2010), and two trials used the Short Form 36 Health Survey (Lunde 2006; Penicka 2007); in one trial the quality of life measure was undefined (You 2008) (see Table 6). Three trials only reported summary results and therefore could not be included in the meta-analysis (Penicka 2007; Roncalli 2010; You 2008). At short-term follow-up there was no difference in quality of life score between treatment groups (standardised mean difference (SMD) 0.58, 95% CI -0.67 to 1.83; 154 participants; three studies). Only one trial reported quality of life at long-term follow-up (Jin 2008); this small trial of 26 participants found a significant difference between groups in favour of cell therapy (SMD 3.23, 95% CI 2.01 to 4.46; 26 participants; one study).

Eight trials measured New York Heart Association (NYHA) class as a measure of performance status at follow-up (Hirsch 2011; Jazi 2012; Jin 2008; Lunde 2006; Penicka 2007; Sürder 2013; Turan 2012; You 2008), although one trial reported summary results only (You 2008). Functional classification of heart failure was also measured in one further trial but it was unclear whether this was NYHA class (Karpov 2005). At short-term follow-up, in five trials there was no difference in NYHA class at the time of follow-up between patients who received cell therapy and those who did not (mean difference (MD) -0.07, 95% CI -0.24 to 0.09; 398 participants; five studies). Similarly, at long-term follow-up in four trials there was no difference in NYHA class (MD -0.23, 95% CI -0.53 to 0.07; 237 participants; four studies) (Analysis 1.10), with considerable heterogeneity between studies  $(l^2 = 80\%)$ .

The use of exercise tests to measure performance was reported in six trials (Colombo 2011; Grajek 2010; Huikuri 2008; Karpov 2005; Lunde 2006; Piepoli 2010). Exercise performance was evaluated using a treadmill test (Grajek 2010; Piepoli 2010), a six minute walk test (Karpov 2005), an electrically braked bicycle ergometer (Lunde 2006), and a symptom-limited maximal exercise test (Huikuri 2008). The method of measuring exercise tolerance was not reported in one trial (Colombo 2011) (see Table 6); we excluded this trial from meta-analyses of exercise tolerance as median rather than mean values were reported. Meta-analysis of the remaining five trials showed no difference in exercise tolerance at short-term followup between patients who received cell therapy and those who did not (SMD 0.19, 95% CI -0.06 to 0.43; 267 participants; five studies) (Analysis 1.11). Similarly there were no differences in maximum VO<sup>2</sup> (MD 1.15 mL/kg/min, 95% CI -0.77 to 3.07; 175 participants; three studies) (Analysis 1.12), VE/VCO<sup>2</sup> slope (MD 0.28, 95% CI -1.02 to 1.57; 174 participants; three studies) (Analysis 1.13) or peak heart

rate (MD 0.55 bpm, 95% CI -6.79 to 7.89; 198 participants; three studies) (Analysis 1.14). Two trials reported exercise tolerance at long-term follow-up (Grajek 2010; Piepoli 2010); although the latter trial did not report endpoint values. In the remaining trial there was no difference between treatment groups (SMD -0.05, 95% CI -0.68 to 0.58; 45 participants; one study) (Analysis 1.11).

## Left ventricular ejection fraction (LVEF)

In order to limit possible heterogeneity, we have subgrouped trials reporting LVEF by the method of measurement. Results are shown in forest plots for the combined analyses of mean change from baseline and endpoint values as well as separately, as described in the Methods section.

Twelve trials used multiple methods to measure left ventricular function (Angeli 2012; Cao 2009; Grajek 2010; Huang 2006; Huikuri 2008; Lee 2014; Lunde 2006; Nogueira 2009; Piepoli 2010; Plewka 2009; Roncalli 2010; Schachinger 2006). Two trials measured these outcomes by three methods: MRI, echocardiography and single photon emission computed tomography (SPECT) (Lunde 2006), or MRI, echocardiography and radionuclide ventriculography (RNV) (Roncalli 2010). The 10 remaining trials each measured these outcomes using two methods: five used echocardiography and SPECT (Angeli 2012; Cao 2009; Lee 2014; Piepoli 2010; Plewka 2009), two used MRI and left ventricular angiography (Huang 2006; Schachinger 2006), two used echocardiography and RNV (Grajek 2010; Nogueira 2009), and one used left ventricular angiography and echocardiography (Huikuri 2008). Baseline LVEF values for each trial are given in Table 7 for each method of measurement.

#### (i) Magnetic resonance imaging (MRI)

Five trials measured baseline LVEF by MRI after cell administration, at one to three days after cells (Tendera 2009), at three to five days after cells (Janssens 2006), between four days prior to six days after cells (Schachinger 2006), after one week (Huang 2006), and after two to three weeks (Lunde 2006); these trials have been pooled alongside the outcome data for all other trials.

Fifteen trials reported LVEF measured by MRI at short-term followup (Hirsch 2011; Huang 2006; Janssens 2006; Lunde 2006; Quyyumi 2011; Roncalli 2010; Schachinger 2006; Sürder 2013; Tendera 2009; Traverse 2010; Traverse 2011; Traverse 2012; Wohrle 2010; Wollert 2004; Yao 2009), with all but two trials, Huang 2006 and Yao 2009, reporting mean change from baseline values. In the combined analysis of mean change from baseline and endpoint values, there was no evidence for a difference in mean LVEF between treatment arms (MD 1.05, 95% CI -0.56 to 2.67; 1135 participants; 15 studies); we observed substantial heterogeneity across studies ( $I^2 = 64\%$ ) (Analysis 1.15).

At long-term follow-up, mean change from baseline values were reported in five trials (Hirsch 2011; Janssens 2006; Sürder 2013; Wohrle 2010; Wollert 2004); a further five trials reported endpoint values only (Lunde 2006; Schachinger 2006; Traverse 2012; Yao 2009; Zhukova 2009), although in one trial LVEF was only reported for two patients (Zhukova 2009); we therefore excluded this trial from the meta-analysis. In the five trials that reported mean change from baseline values, there was no evidence for a difference in mean change in LVEF from baseline between groups (MD 0.03, 95% CI -1.72 to 1.78; 438 participants; five studies). Similarly, endpoint values reported in eight trials showed no difference between patients who received cell therapy and those who did not (MD 1.40, 95% CI -1.54 to 4.34; 551 participants; eight studies), with no difference observed in the combined analysis of mean change from baseline and endpoint values (MD 1.27, 95% CI -1.14 to 3.68; 718 participants; nine studies). There was evidence of substantial heterogeneity across studies ( $I^2 = 66\%$ ) (Analysis 1.16).

We observed substantial heterogeneity at both short-term ( $I^2 = 64\%$ ) and long-term follow-up ( $I^2 = 66\%$ ).

We carried out exploratory subgroup analyses to investigate potential sources of heterogeneity as described in the Methods section. There was no significant evidence for subgroup differences when we stratified trials by baseline LVEF (Analysis 6.3; Analysis 6.4), cell dose (Analysis 8.3; Analysis 8.4), timing of cell administration (Analysis 9.3; Analysis 9.4) or use of heparinised cell solution (Analysis 9.3; Analysis 9.4) at either short-term or long-term follow-up. There were insufficient trials using cells other than mononuclear cells to perform subgroup analysis for cell type.

#### (ii) Echocardiography

LVEF measured by echocardiography at short-term follow-up was reported in 20 trials (Angeli 2012; Cao 2009; Colombo 2011; Gao 2013; Ge 2006; Grajek 2010; Huang 2007; Huikuri 2008; Jin 2008; Karpov 2005; Lee 2014; Lunde 2006; Nogueira 2009; Penicka 2007; Piepoli 2010; Plewka 2009; Roncalli 2010; Ruan 2005; Xiao 2012; You 2008). Of these 20 trials, all reported endpoint LVEF values but only six reported mean change from baseline values (Gao 2013; Huang 2007; Huikuri 2008; Lee 2014; Lunde 2006; Plewka 2009). Metaanalysis of these six trials showed evidence for a difference in mean change from baseline LVEF in favour of cell therapy (MD 2.72, 95% CI 1.50 to 3.95; 372 participants; six studies). This improvement in LVEF associated with cell therapy was also seen in the combined analysis of all 20 trials (MD 2.31, 95% CI 1.30 to 3.33; 862 participants; 20 studies) (Analysis 1.17). The observed difference was robust to sensitivity analysis excluding the trial that administered cells via the coronary artery (Nogueira 2009).

At long-term follow-up, only three trials reported mean change in LVEF from baseline (Gao 2013; Piepoli 2010; Plewka 2009). Metaanalysis of these three trials showed no evidence for a difference in mean change from baseline values between trial arms (MD 1.35, 95% CI -2.25 to 4.96; 127 participants; three studies). However, in nine trials that reported LVEF values at the time of follow-up (Angeli 2012; Cao 2009; Colombo 2011; Gao 2013; Grajek 2010; Jin 2008; Lunde 2006; Penicka 2007; Piepoli 2010), LVEF values at follow-up were higher in patients who received cell therapy than those who did not (MD 2.87, 95% CI 1.42 to 4.31; 377 participants; nine studies). Evidence for an improvement in LVEF associated with cell therapy was also seen in the combined analysis (MD 2.09, 95% CI 0.74 to 3.44; 433 participants; 10 studies) (Analysis 1.18).

The observed heterogeneity was moderate ( $I^2 = 37\%$ ) at short-term follow-up and low at long-term follow-up ( $I^2 = 11\%$ ) and therefore we performed no exploratory subgroup analyses for LVEF measured by echocardiography.

## (iii) SPECT

Seven trials reported LVEF measured by SPECT at short-term follow-up (Angeli 2012; Cao 2009; Lee 2014; Lunde 2006; Meluzin 2008; Piepoli 2010; Plewka 2009), although only five trials reported mean change from baseline values (Lee 2014; Lunde 2006; Meluzin 2008; Piepoli 2010; Plewka 2009). In one trial, endpoint values

(but not mean change values) reflect an expanded cohort (Meluzin 2008). Meta-analysis showed a greater mean change from baseline values in patients who received cell therapy compared with those who did not (MD 2.72, 95% CI 0.23 to 5.21; 286 participants; five studies). This effect was also demonstrated in six trials that reported LVEF values measured by SPECT at follow-up (MD 2.19, 95% CI 0.58 to 3.81; 375 participants; six studies) and in the combined analysis of mean change from baseline and endpoint values (MD 2.52, 95% CI 0.59 to 4.44; 394 participants; seven studies) (Analysis 1.19).

An improvement in LVEF measured by SPECT associated with cell therapy was also found at long-term follow-up in four trials (Angeli 2012; Cao 2009; Meluzin 2008; Piepoli 2010) (MD 4.42, 95% CI 2.68 to 6.16; 200 participants; four studies); this improvement was observed in both trials that reported mean change from baseline (MD 5.63, 95% CI 1.77 to 9.49; 92 participants; two studies) and trials that only reported endpoint values (MD 3.46, 95% CI 0.82 to 6.11; 181 participants; three studies) (Analysis 1.20).

There was no evidence for heterogeneity at long-term follow-up ( $I^2 = 2\%$ ) and there was moderate heterogeneity at short-term follow-up ( $I^2 = 39\%$ ) and we therefore did not perform subgroup analyses.

#### (iv) Left ventricular angiography

Nine trials reported LVEF measured by left ventricular angiography at short-term follow-up (Chen 2004; Huang 2006; Huikuri 2008; Jazi 2012; Schachinger 2006; Suarez de Lezo 2007; Turan 2012; Wang 2014; Yao 2006). All trials reported endpoint LVEF values but only three reported mean change from baseline values (Huikuri 2008; Schachinger 2006; Suarez de Lezo 2007). Meta-analysis of these three trials showed a evidence for a difference in mean change from baseline LVEF in favour of cell therapy (MD 6.43, 95% CI 0.60 to 12.27; 279 participants; three studies). In the combined analysis of all nine trials, this effect remained (MD 5.09, 95% CI 0.95 to 9.24; 711 participants; nine studies) with considerable heterogeneity across studies ( $I^2 = 95\%$ ) (Analysis 1.21). Only one trial reported longterm follow-up of LVEF measured by left ventricular angiography (Turan 2012); this trial found a significantly higher mean LVEF at follow-up in patients who received cell therapy compared with those who did not (MD 8.00, 95% CI 4.27 to 11.73; 62 participants; one study) (Analysis 1.22). We observed considerable heterogeneity at short-term follow-up ( $I^2 = 95\%$ ). Visual inspection of the forest plot revealed two potential outliers (Chen 2004; Yao 2006), although considerable heterogeneity remained when we excluded these two studies from the analysis. Exploratory subgroup analyses revealed that when trials were subgrouped according to cell dose, metaanalysis of two trials that used >  $10^9$  cells showed a significant difference when compared to six trials that used >  $10^8$  and  $\le 10^9$ cells (test for subgroup differences, P value = 0.0003) (Analysis 8.5), although substantial heterogeneity remained in both subgroups. We found no subgroup differences when we subgrouped trials by either timing of cell administration (P value = 0.12) (Analysis 9.5) or use of heparinised cell solution (P value = 0.26) (Analysis 10.5). The limited number of trials within groups precluded subgroup analysis by baseline LVEF or type of cells.

#### (v) Radionuclide ventriculography (RNV)

Three trials reported LVEF measured by radionuclide ventriculography (Grajek 2010; Nogueira 2009; Roncalli 2010). There were no differences between treatment groups in analyses

of mean change in LVEF from baseline (MD 0.91, 95% CI -3.11 to 4.94; 118 participants; two studies), mean LVEF at endpoint (MD 1.08, 95% CI -4.88 to 7.04; 157 participants; three studies), or in the combined analysis (MD 1.79, 95% CI -1.86 to 5.43; 157 participants; three studies) (Analysis 1.23). Only one trial reported LVEF measured by radionuclide ventriculography at long-term follow-up (Grajek 2010); this trial found no evidence for a difference between treatment groups in LVEF measured at long-term follow-up (MD 6.30, 95% CI -1.03 to 13.63; 39 participants; one study) (Analysis 1.24).

## DISCUSSION

Cell transplantation has been developed clinically for over 40 years in patients with haematological malignancies (e.g. haematopoietic stem cell transplantation), but its application as a treatment for other conditions, such as heart disease, has only been possible since 2002. Over the last 13 years clinical evidence from randomised controlled trials (RCTs) has become available, allowing the robust evaluation of the safety of this alternative treatment in patients who have suffered a recent acute myocardial infarction (AMI). Meta-analyses in cell therapy can help to show the safety of the approach and generate hypotheses, but due to the extent of the heterogeneity of the biologically active product, analysis of efficacy has to be marked with a great caveat. The present study is an update of the Cochrane systematic review published by us previously (Clifford 2012).

#### Nature of the intervention

Forty-one RCTs, including 2732 participants, were eligible for inclusion in this updated Cochrane review. The characteristics of the interventions are summarised in Table 2. All included studies compared cell treatment with no cells in addition to the standard primary intervention for revascularisation (primary angioplasty and/or thrombolytic therapy) and standard medical therapy. Participants recruited to these trials have had a recent AMI and received treatment (intervention) or control (or placebo) following successful revascularisation of the infarct-related coronary artery (IRCA). The cell-based treatment was administered by an interventional cardiologist as a single bolus, usually by infusion into the IRCA using a balloon catheter. One trial compared two intervention groups, comparing treatment delivered by intracoronary vein infusion with arterial infusion (Nogueira 2009). However, unlike traditional drugs used in cardiology, which possess much simpler chemical and pharmacological characteristics, autologous cell therapies are experimental interventions with much more complex and individualised properties. Therefore it is not surprising that there was substantial clinical heterogeneity and diversity within and between trials: the characteristics of the participants, the type and size of infarct and the baseline outcome values (e.g. left ventricular ejection fraction (LVEF)) at admission all differed. Cell type, dose and time of administration as well as the media where cells were re-suspended and whether the participants in the comparator arm received placebo or not also differed. There is no standard definition of an 'active' cell product at present. This is because the number of administered cells cannot be equated to active dose and the number of cells retained in the target region might be affected by disease and patient-related factors. Having said that, all trials included in this review delivered cells of bone marrow origin, with bone marrow mononuclear cells being the starting cell population. Thirty-eight trials isolated cells from bone marrow aspirates and enriched the mononuclear cell population

by gradient centrifugation. One trial infused an enriched CD34 fraction (Quyyumi 2011), and one trial infused enriched CD133positive cells (Colombo 2011), whilst another trial compared the effect of unfractionated mononuclear cells with CD34+/CXCR4+ cells (Tendera 2009). Five trials cultured and administered bone marrow-derived mesenchymal stromal cells (Gao 2013; Lee 2014; Wang 2014; Xiao 2012; You 2008). The trials also differed in their design (e.g. blinded versus open-label), the length of follow-up (short and long-term) and the methodology used to measure surrogate outcome data (e.g. magnetic resonance imaging (MRI), echocardiography, single photon emission computed tomography (SPECT), etc.).

## **Main findings**

There are 11 new trials included in this update of the Cochrane review, but the individual trials are still too small. Pooling the data together, we can conclude the following.

- There was no evidence for a difference in the risk of allcause mortality, cardiovascular mortality, incidence of rehospitalisation for heart failure, re-infarction, arrhythmias, restenosis or target vessel revascularisation in cell-treated patients compared to controls.
- Accordingly, we found no evidence for a difference in the composite measure of major adverse cardiac events (MACE) defined by death, re-infarction and re-hospitalisation for heart failure between treated patients and the control group.
- There were no major differences in periprocedural adverse events associated with cell treatment.
- The treatment was associated with no improvement in LVEF measured by MRI. We observed no differences between treatment groups in mean New York Heart Association (NYHA) class, quality of life measures and exercise/performance measures at short-term follow-up. There were too few trials with long-term follow-up that measured NYHA class, quality of life or exercise/performance to draw meaningful conclusions.
- Taken together, the results of these meta-analyses suggest that bone marrow-derived cell therapy has no beneficial effect for patients who have suffered AMI. The quality of the evidence presented here is moderate due to imprecision: the information size criterion has not been met, meaning that this systematic review and meta-analysis is underpowered.

#### **Study limitations**

There are a number of limitations to the strength of any conclusion that can be drawn from the evaluation of the included trials. These include sample sizes of the individual trials, statistical power, clinical heterogeneity and risk of bias of the included trials (please see below).

## Sample size and statistical power

In general, the sample sizes were small in all trials included, perhaps with the exception of three trials that included at least 200 participants (Schachinger 2006; Sürder 2013; Tendera 2009). At present, results from the first large phase III randomised trials

to robustly determine the efficacy of this treatment are lacking. Therefore, systematic reviews and meta-analysis of pooled trial data can be used to generate hypotheses and to compensate for the lack of statistical power in individual trials.

Cumulative meta-analyses may result in type I errors due to an increased risk of random error arising from repeated testing of accumulating data (Borm 2009; Hu 2007; Lan 2003). Trial sequential analysis provides a method of adjusting the thresholds for statistical significance while maintaining the overall desired type I error rate (Wettersley 2008). We applied trial sequential analysis to the primary outcome of all-cause mortality, assuming a long-term mortality incidence rate of 6.1% in the control group (as observed in our control data) and a relative risk reduction of 35% (equivalent to the reduce risk of mortality associated with percutaneous coronary intervention (PCI) (Hartwell 2005). In our analysis, the cumulative Z-curve for all-cause mortality did not cross the conventional thresholds or trial sequential monitoring boundaries (TSMB) for significance. The required information size was 3275 participants, suggesting that even the current metaanalysis is considerably underpowered to detect a relative risk reduction of this magnitude. The required information size to detect significant effects in cardiovascular mortality and composite MACE was 3064 and 1572 participants, respectively.

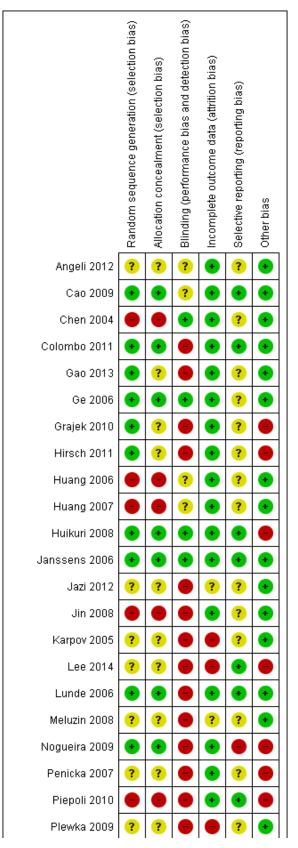

The effect of intracoronary reinfusion of bone marrow-derived mononuclear cells (BMMNC) is being assessed in a pan-European Phase III trial (the BAMI trial) (NCT01569178). This trial is well-powered and is planned to recruit 3000 participants who have suffered a recent myocardial infarction and have reduced LVEF ( $\leq$  45%) following successful revascularisation. Primary and secondary outcomes include death, cardiac death, re-hospitalisation for myocardial infarction, target vessel revascularisation (TVR), heart failure, implantation of implantable cardioverter-defibrillator/ cardiac resynchronisation therapy (ICD/CRT) device, stroke, syncope or arrhythmias and incidence and severity of adverse events, with an estimated completion date of May 2018.

## **Risk of bias and heterogeneity**

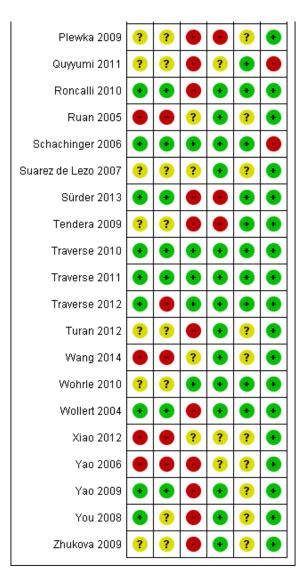

This systematic review is based on a comprehensive search strategy, but despite this the possibility of publication and reporting bias cannot be ruled out completely. Risk of bias is present in the included trials, as summarised in Figure 4. All trials stated that they randomised the participants, but only 49% (n = 20) and 34% (n = 14) of the included trials documented adequate methods for the generation of randomised sequences and concealment of treatment allocation, respectively. Blinding (performance and detection bias) was reported in 22% (n = 9) of the included trials, whilst the remaining 32 trials were described either as not blinded (n = 24) or blinding was unclear (n = 8). Attrition bias was low in 76% (n = 31) of the included trials, whilst it was unclear or high in the remaining trials. Finally, selective reporting bias was low in 41% (n = 17) of the included trials. Sensitivity analyses conducted for the major outcome of all-cause mortality showed that excluding those trials with high risk of selection, attrition or performance bias had a negligible effect on all-cause mortality.

Figure 4. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

## Figure 4. (Continued)

In summary, this review finds that the results from the metaanalysis are of moderate quality for the primary outcomes (see Summary of findings for the main comparison) due to the information size criterion not being met (imprecision). Therefore, further research may change the estimate of the treatment effect. These results may be regarded as optimistic, however the evidence from this review, from our previous Cochrane reviews and from the recent individual patient data analysis, Gyöngyösi 2015, appears to support the conclusion that bone marrow cell therapies may not reduce the risk of clinical outcomes in patients with AMI.

Our previous versions of this Cochrane review have shown a considerable degree of heterogeneity among trials, which has been extensively explored (Clifford 2012; Fisher 2012; Martin-Rendon 2008a; Martin-Rendon 2008b). Interestingly, heterogeneity is negligible for the primary outcomes of this review, suggesting little variation in treatment effect. However, clinical heterogeneity is still present, which justifies using a random-effects model in all meta-analyses conducted. We have attempted to address some of the issues of heterogeneity by conducting exploratory subgroup analyses. One example is the timing of cell delivery. It is important

to make the distinction between early and late administration of cells as remodelling of the damaged tissue is very different at seven to 10 days to four weeks. We have considered carefully the option of restricting the inclusion criteria to trials which deliver cells within 10 days. However, as there are several key trials that would be excluded from this review as a subset of patients received cells after 10 days (between three and 12 days (Penicka 2007; Plewka 2009; Tendera 2009)), we have opted to conduct subgroup analyses for timing of cell delivery. Similarly, we have stratified the length of follow-up at less than 12 months and 12 months or more. In this case, the latter category seems to be more diverse, with one trial reporting a mean follow-up of over eight years (Karpov 2005). Interestingly, this trial provides the most negative results in a number of clinical outcomes. One possible explanation is that the risk of mortality over longer-term follow-up would be increased in both treated and control patients, and therefore any observed differences between the two groups would decrease as the length of follow-up increased.

Cochrane Library

Trusted evidence. Informed decisions. Better health.

#### Quality of life and exercise/performance status

Since our last update of this Cochrane review (Clifford 2012), more trials have reported patient-centred outcomes, such as quality of life and exercise or performance status. However, quality of life and performance measures during long-term follow-up are still underreported. In some cases only one trial has reported these outcomes, thus precluding any further analysis. Where metaanalysis was feasible, no differences between treated patients and controls were observed.

#### Left ventricular ejection fraction (LVEF)

We subgrouped LVEF data according to the method of measurement. Although each method has its limitations, it is widely accepted that MRI is the gold standard method to measure surrogate outcomes such as LVEF. A limited number of studies presented LVEF data as mean change from baseline. Many studies presented both mean change from baseline and mean value at endpoint and results are broadly similar whichever measure is used (see, for example, Analysis 1.16). We present forest plots for both mean change from baseline and endpoint values for clarity and transparency. There was evidence for an improvement in LVEF measured by MRI from baseline at both short and long-term followup. There was no improvement in LVEF measured by MRI from baseline or at endpoint, both at short and long-term follow-up. Although there might be an indication of an improvement of LVEF when measured by echocardiography, SPECT or left ventricular angiography, the effect sizes are within the range of 2% to 5%, which is accepted not to be clinically relevant.

#### Subgroup analyses

Where appropriate, exploratory subgroup analysis investigated the effects of baseline cardiac function (LVEF), cell dose, type and timing of administration, as well as the use of heparin in the final cell solution. Most of the subgroup analyses found no evidence for differences between groups, with the exception of long-term mortality subgrouped by cell dose. The results suggest that there is no evidence for a reduction in mortality associated with a cell infusion of less than  $10^8$  cells, whilst there is a reduction in long-term mortality in favour of cell therapy with  $10^8$  to  $10^9$  cells. There were very few trials that administered more than  $10^9$  cells to draw robust conclusions. However, in view of the low number of trials included, these results should be considered with caution.

Baseline LVEF has been previously reported to be an effect modifier (Beitnes 2009; Schachinger 2009), although we found no evidence for subgroup differences according to baseline LVEF. Ideally, subgroup analyses of baseline cardiac function would include studies where all subgroup patients have a baseline LVEF of, say,  $\leq$  45% or > 45%, and such an analysis could be implemented with the use of individual patient data (Gyöngyösi 2015). Unfortunately, few of the included studies used an LVEF threshold as part of their inclusion criteria. Furthermore, we used LVEF baseline measures obtained by MRI as the gold standard, which is usually done after revascularisation and so any baseline LVEF values used as eligibility criteria are unlikely to have been obtained by MRI. Subgroup analysis of studies stratified by mean LVEF using the median value as the subgroup threshold (as defined in the previous version of this review) provides a crude measure of whether baseline cardiac function is associated with efficacy, which will merely have reduced power to detect subgroup effects.

# Agreements and disagreements with other studies or reviews

In this update of the Cochrane review we have focused on clinical outcomes such as death, cardiovascular death, reinfarction (MI), arrhythmias, restenosis, target vessel revascularisation and rehospitalisation for heart failure. We have included MACE, defined as death, reinfarction (MI) and re-hospitalisation for heart failure.

Our results suggest that cell therapy does not appear to have a beneficial effect in patients who have experienced a recent AMI. Although this is in agreement with the previous version of this review (Clifford 2012), and with recent systematic reviews and meta-analysis on cell therapies for patients with AMI (de Jong 2014; Delewi 2014; Gyöngyösi 2015), the present update of the Cochrane review presents long-term data that are lacking from previous meta-analysis (de Jong 2014; Gyöngyösi 2015). de Jong 2014 reported a meta-analysis of 22 cell-based therapy RCTs (2037 participants) and found that cell therapy had no effect on major adverse clinical cardiac events including all-cause mortality for a median follow-up of six months. In the first prospective individual patient data (IPD) meta-analysis including 12 trials (1252 participants), Gyöngyösi 2015 confirmed no significant differences in all-cause mortality. Like the present Cochrane review, previous meta-analyses have shown low procedural adverse events and low incidence of clinical endpoints.

The picture is somewhat more confusing when measuring surrogate outcomes such as LVEF. Mean changes scores may be less efficient for outcomes that are difficult to measure with precision (Higgins 2011), and it may be that one has to take this into consideration when describing continuous surrogate outcomes such as LVEF. The present Cochrane review and meta-analysis shows no improvement in LVEF in favour of cell therapy when measured by MRI during either short-term or long-term follow-up. Whilst de Jong 2014 observed a significant improvement in LVEF during short-term follow-up (in 1513 participants), Gyöngyösi 2015 observed no significant improvement (in 734 participants) when analysing individual patient data. de Jong 2014 found that the improvement in LVEF in favour of cell therapies was not sustained long-term and explained this by a gradual increase in LV volumes during the first year after AMI in reperfused patients (Engblom 2009).

Our data are in disagreement with results obtained in systematic reviews and meta-analysis where the cell therapies have been administered to patients with chronic ischaemic heart disease and heart failure (Afzal 2015; Fisher 2014; Fisher 2015; Wen 2012), which may indicate that heart failure patients may benefit more from cell-based therapies than AMI patients.

## Summary

The first-generation clinical trials were designed to prove safety of the procedure but were not statistically powered to assess efficacy of the treatment and longer-term effects on survival free of major associated cardiac events. This systematic review and metaanalysis of pooled trials suggests that cell-based therapies do not lead to a reduction in hard clinical outcomes such as all-cause mortality, cardiovascular mortality, rehospitalisation for heart failure, target vessel re-vascularisation or composite measures of MACE, or indeed an improvement in LVEF as a surrogate of heart function. Although the quality of this evidence is moderate due

to imprecision (Summary of findings for the main comparison), the findings of this review are consistent with the previous version (Clifford 2012), and with the recently published individual patient data analysis (Gyöngyösi 2015). Although these results are robust to sensitivity analyses, this systematic review is most likely underpowered. There is ultimately no substitute for adequately powered phase III RCTs, such as the BAMI trial.

The findings from this systematic review provide further support to previous statements by the National Institute of Clinical Excellence (NICE) and the European Society of Cardiology (ESC) Task Force (Bartunek 2006) that stem cell therapy remains "an experimental therapy". Evidence reported to date, although almost entirely from small trials, does not support the incorporation of stem cell therapy in the management of patients with AMI. A re-evaluation of this systematic review is warranted on completion of the BAMI trial, expected in 2018.

## AUTHORS' CONCLUSIONS

## Implications for practice

Evidence from the included trials indicates that adult cell-based therapies seem to be safe. The incidence of mortality following successful revascularisation of the culprit artery is very low and the introduction of primary angioplasty as the standard primary intervention in acute myocardial infarction (AMI) has already reduced short-term mortality by 33% and re-infarction by 50%. However, there seems currently to be insufficient evidence to suggest that cell therapy reduces mortality and morbidity beyond standard therapy in this group of patients. Most of the evidence comes from small trials and small numbers of events. Larger and adequately powered clinical trials, such as the BAMI trial, are required to robustly assess the efficacy of cell-based therapies post-AMI.

## Implications for research

This review shows that currently there is no evidence for a reduction in mortality and morbidity when bone marrow-derived

stem cell treatment is administered to patients who had standard primary intervention following AMI. Further research may be justified to address current uncertainties, such as the mechanism of action and the need for patient selection. The first phase III trials to assess hard clinical outcomes are underway. Future clinical trials should be adequately powered, consider the best surrogate outcomes to measure and the best method to measure them, and should standardise composite major adverse cardiac events (MACE). They should also reduce the risk of selection, attrition, performance and reporting bias.

## ACKNOWLEDGEMENTS

We acknowledge with thanks the contributions of Susan Brunskill, Dr David Clifford, Professor C. Hyde, Dr Simon Stanworth and Professor Suzanne Watt, for their contribution to previous versions of this review. We thank Pat Tsang for the translation of Xiao 2012 from Mandarin to English for this update and Mrs F-J Lu for translating papers from Mandarin to English in the original version of this review.

We are grateful to those trial investigators who kindly responded to our questions and requests for further clarification or information on published and unpublished studies in this update of the review: Dr B Assmus and Prof. V Schachinger (JW Goethe University, Frankfurt, Germany), Prof. M Tendera and Prof. W Wojakowski (Medical University of Silesia, Poland), Prof. S Grajek (Poznan University of Medical Science, Poland), Prof. L Chojnowska (Institute of Cardiology, Warsaw, Poland), Dr K Lunde (Oslo University Hospital, Norway), Prof. M Plewka and Dr P Lipiec (Medical University of Lodz, Poland), Prof. V Ryabov (FBGU Institute of Cardiology SB RAMS, Russia), Prof. A Hirsch (University do Amsterdam, The Netherlands), Prof. RG Turan (University Hospital Cologne, Germany), Prof. P Lemarchand (University of Nantes, France), Prof. J Roncalli (Hôpital Ranguei, Toulouse, France) and Dr M Piepoli (Guglielmo da Saliceto Policherurgico Hospital, Italy).

\* Indicates the major publication for the study

ngeli 2012			
Methods	Type of study: parallel RCT		
	Type of publication: short report		
	Source of funding: not reported		
	Country of origin: Brazil		
	Number of centres: 1		
	Dates of trial enrolment: not reported		
	<i>Length of follow-up</i> : 12 months		
	Number (N) of participants randomised to each arm: 11 in the treatment arm, 11 in the control arm		
	Number (N) of participants analysed (primary outcome) in each arm: 11 in the treatment arm, 11 in the		
	control arm		
Participants	<i>Population</i> : AMI successfully treated with PCI and with LVEF < 45%		
•	Age, mean (SD) each arm: not reported		
	Sex, % male in each arm: not reported		
	Number of diseased vessels: not reported		
	Number of stunned hyperkinetic, etc segments: not reported		
	Time from symptom onset to initial treatment: 5 to 9 days post-symptoms		
	Statistically significant baseline imbalances between the groups?: none		
Interventions	Intervention arm: BMMNC		
	<i>Type of stem cells</i> : bone marrow-derived stem cells (mononuclear cells-MNC)		
	Summary of how stem cells were isolated and type and route of delivery: methods of cell isolation not re		
	ported		
	Dose of stem cells: a single dose of 2.6 ( $\pm$ 1.6) x 10 <sup>8</sup> /mL mononuclear cells		
	<i>Timing of stem cell procedure</i> : cells infused 5 to 9 days following the onset of symptoms and 4 hours following harvest. Intracoronary infusion of cells in the infarct-related artery		
	Comparator arm: not reported		
Outcomes	Primary outcomes: not reported		

Stem cell treatment for acute myocardial infarction (Review)

\_

Angeli 2012 (Continued)

Secondary outcomes: LVEF, LV perfusion defect, adverse events Outcome assessment points: 4 and 12 months Method(s): echocardiography, SPECT

### Notes

### **Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Unclear risk	The trial was described as randomised but the method of randomisation was not reported
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported
Blinding (performance bias and detection bias) All outcomes	Unclear risk	The trial was described as "double blind" and a placebo was used. It was un- clear whether the control group underwent bone marrow aspiration. Blinding of outcome assessors was not reported
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical outcomes and scientific outcomes
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

#### Cao 2009

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : Shanxi Scientific and Technical Key Project, Xijing Research Boosting Program on Stem Cell Research (No. XJZT08Z04), Xijing Research Boosting Program on Cardiac Microvascular For- mation Research (No. XJZT07Z05) and National Basic Research Program of China	
	<i>Country of origin</i> : China <i>Number of centres</i> : 1	
	Dates of trial enrolment: 07/03 to 03/04 Length of follow-up: 48 months Number (N) of participants randomised to each arm: 41 in treatment arm/45 in control arm Number (N) of participants analysed (primary outcome) in each arm: 41 in treatment arm/45 in control arm	
Participants	<i>Population</i> : AMI, within 12 hours. PCI within 12 hours <i>Age, mean (SD) each arm</i> : 50.7 (SEM 1.1) years in treatment arm, 51.0 (SEM 1.0) years in control arm <i>Sex, % male in each arm</i> : 95.1% in treatment arm, 93.3% in control arm	
	Number of diseased vessels: 1 Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: 6.5 (0.3) hours (mean ± SEM) before PCI in treatment arm, 6.8 (0.3) (mean ± SEM) hours before PCI in control arm Statistically significant baseline imbalances between the groups?: none	
Interventions	Intervention arm: BMMNC	

Stem cell treatment for acute myocardial infarction (Review)

Cao 2009 (Continued)	
	<i>Type of stem cells</i> : bone marrow-derived stem cells (mononuclear cells-MNC) <i>Summary of how stem cells were isolated and type and route of delivery</i> : 40 mL bone marrow aspirated 7 days after PCI. Density gradient centrifugation (Ficoll) used to isolate BMMNC. Mononuclear cell lay- er harvested, washed 3 times and re-suspended in 10 mL heparinised saline. Intracoronary infusion us- ing PCI technique, over-the-wire balloon catheter advanced to the proximal part of the stented culprit lesion, inflated with 4 to 5 Atm pressure for 1 minute to occlude blood flow. At the same time MNC sus- pension injected into the IRA. Procedure repeated 4 times <i>Dose of stem cells</i> : 4 doses of 2.5 mL cell suspension containing ~1.25 x 10 <sup>8</sup> MNC for a total of ~ 5.00 x 10 <sup>8</sup> MNC
	<i>Timing of stem cell procedure</i> : primary PCI performed within 12 hours of onset of symptoms, cell infusion performed 7 days after primary PCI
	Comparator arm: patients received a 10 mL placebo intracoronary saline injection
Outcomes	Primary outcomes: ESV, EDV, LVEF, WMSI, infarct size, coronary artery restenosis Secondary outcomes: none Outcome assessment points: baseline, 1, 3, 6, 12 and 48 months Method(s): echocardiography, ECG-gated 99m Technetium SPECT, quantitative coronary angiography
Notes	Baseline values taken at day 0 (day of AMI and primary angioplasty) and at day 7 (day of BMMNC treat- ment or sham procedure), day 7 values entered. SPECT was also used to measure infarct size LVEF, ESV and EDV but results were not published

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Random numbers between 0 and 1 were generated and a median value was calculated. Random numbers greater than the median value were allocated to the BMMNC group
Allocation concealment (selection bias)	Low risk	Randomisation details provided in consecutively numbered, sealed envelopes
Blinding (performance bias and detection bias) All outcomes	Unclear risk	The control group did not undergo bone marrow aspiration although they re- ceived an injection of heparinised saline and therefore it is unclear whether participants and clinicians were sufficiently blinded to treatment. Outcome as- sessors were blinded to treatment allocation
Incomplete outcome data (attrition bias) All outcomes	Low risk	1 patient in the BMMNC group (1/41) had transient acute HF seven days after transplant. 1 patient in the control group (1/45) had in-stent restenosis and was subjected to repeat PCI at 1-year follow-up. It is unclear whether these pa- tients were included at follow-up. One additional control had died at 1-year follow-up
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00626145) were reported
Other bias	Low risk	None reported or identified

### Chen 2004

Methods Type of study: parallel RCT Type of publication: full Source of funding: not reported Country of origin: China

Chen 2004 (Continued)	Number of centres: 1			
Participants	<i>Population</i> : AMI, within 12 hours <i>Age, mean (SD) each arm</i> : 58 (7.0) years in treatment arm, 57 (5.0) years in control arm <i>Sex, % male in each arm</i> : 94% in treatment arm, 97% in control arm			
	Number of diseased vessels: 1.6 (0.5) in treatment arm, 1.7 (0.4) in control arm Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: 8.3 (3.8) hours from AMI to PCI in treatment arm; 8.5 (3.9) hours from AMI to PCI in control arm Statistically significant baseline imbalances between the groups?: none			
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: 60 mL of autologous bone mar row was aspirated under local anaesthesia from the ilea of all 69 patients in the morning 8 days after PCI and cultured for 10 days. Cells were harvested and washed 3 to 4 times with heparinised saline, ar the cell suspension was mixed with heparin, filtrated and prepared for implantation 2 hours before im plantation. 6 mL of the cell suspension was injected directly into the target coronary artery through an inflated over-the-wire balloon catheter in the central lumen with high pressure (10 atm). The balloon remained inflated for 2 or more minutes to occlude anterior blood flow just before beginning the BMM NC injection Dose of stem cells: 6 mL containing 8 to 10 x 10 <sup>9</sup> cells/mL Timing of stem cell procedure: 18.4 (0.5) days after PCI Comparator arm: 6 mL standard saline via PCI method			
Outcomes	Primary outcomes: cardiac death			
	ment velocity, LVEF. "C	Left ventricular haemodynamics": functional defect (%), infarcted area move- ardiac functional indexes": LVESV, LVEDV, circumferential shortening, Psyst/ESV, T. Measured by echocardiography and PET		
	Outcome assessment points: baseline, 3 and 6 months			
	<i>Method(s)</i> : PET, echocardiography, NOGA, left ventriculography			
Notes	_			
Risk of bias				
Bias	Authors' judgement	Support for judgement		
Random sequence genera- tion (selection bias)	High risk	This Chinese trial was described as randomised but the method of randomisa- tion was not reported		
Allocation concealment (selection bias)	High risk	Allocation concealment was not reported		
Blinding (performance bias and detection bias) All outcomes	Low risk	The control group underwent bone marrow aspiration and received an injec- tion of saline by the same method as the BMSC group. Blinding of clinicians was not reported. Outcome assessors were blinded to treatment allocation. 3 independent statisticians who had no knowledge of the study collected and analysed outcome data		

analysed outcome data

Stem cell treatment for acute myocardial infarction (Review)

# Chen 2004 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical outcomes and scientific outcomes
Selective reporting (re- porting bias)	Unclear risk	Incomplete data for LVEDV and LVESV were provided in the results although these outcomes are not included in this review. It would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

### Colombo 2011

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : supported by grants from the Italian Ministry of Health (Progetto Ricerca Finalizzata 2002 and 2005, Progetto ex art. 56 2007); the Italian Ministry of University and Research, and the 6FP EU Project - THERCORD. Materials for CD133+ cell separations were kindly provided by Miltenyi Biotec	
	Country of origin: Italy Number of centres: 2	
	<i>Dates of trial enrolment</i> : 10/03 to 10/06 <i>Length of follow-up</i> : 12 months <i>Number (N) of participants randomised to each arm</i> : 5 in the treatment arm, 5 in the control arm <i>Number (N) of participants analysed (primary outcome) in each arm</i> : 5 in the treatment arm, 4 in the control arm	
Participants	<i>Population</i> : STEMI with PCI within 6 hours of symptom onset <i>Age, mean (SD) each arm</i> : median 54 (range 47 to 60) years in treatment arm, median 56 (range 44 to 58) years in control arm <i>Sex, % male in each arm</i> : 100% in both trial arms	
	Number of diseased vessels: 1 Number of stunned hyperkinetic, etc segments: mean 4.2 (1.6) in treatment therapy arm, mean 3.8 (1.3) in control arm Time from symptom onset to initial treatment: median 265 hours from symptoms onset to PCI; cell ther- apy on day 9 to 16 after PCI Statistically significant baseline imbalances between the groups?: none	
Interventions	Intervention arm: CD133 <sup>+</sup> Type of stem cells: CD133 selected bone marrow-derived stem cells Summary of how stem cells were isolated and type and route of delivery: bone marrow aspiration fol- lowed by immunomagnetic selection with specific monoclonal antibody using the CliniMacs System. Re-suspended in 10 mL (± 2) of normal saline solution (0.9% NaCl) with 10% human serum albumin. De- livery via intracoronary infusion by PCI over the wire balloon catheter technique Dose of stem cells: median 5.9 x 10 <sup>6</sup> (range 4.9 +/- 13.5) CD133 <sup>+</sup> cells Timing of stem cell procedure: cell infusion was done 9 to 13 days following STEMI and successful PCI	
	Comparator arm: no additional therapy (control)	
Outcomes	<i>Primary outcomes</i> : 1. any adverse event during hospital stay, 2. PET-derived changes in myocardial per- fusion and infarct size at 12 months, and 3. variations in LVDV, LVEF and WMSI at 12 months by echocar- diography <i>Secondary outcomes</i> : all-cause death, cardiac death, symptomatic heart failure and coronary symp- toms requiring hospitalisation and target vessel revascularisation <i>Outcome assessment points</i> : 3, 6, 12 months	

Stem cell treatment for acute myocardial infarction (Review)

Colombo 2011 (Continued)

Method(s): echocardiography, gated PET

Notes

### **Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Randomisation was undertaken using a permuted block randomisation sys- tem and numbered containers
Allocation concealment (selection bias)	Low risk	Randomisation, patient enrolment and assignment to study group was done by a blinded co-ordinator
Blinding (performance bias and detection bias) All outcomes	High risk	Controls did not undergo bone marrow aspiration; no placebo was adminis- tered to controls. After randomisation, study processes were blinded to the re- searchers involved in echocardiography and PET evaluation
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical outcomes and scientific outcomes at 6 months. 1 patient in the control group underwent heart transplantation 6 months after STEMI and was not included in 12-month evaluation
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00400959) were reported
Other bias	Low risk	None reported or identified

### Gao 2013

Methods	Type of study: parallel RCT Type of publication: full Source of funding: grant of the National Advanced Technology Development Plan of China		
	<i>Country of origin</i> : China <i>Number of centres</i> : 4		
	Dates of trial enrolment: 05/08 to 11/09 Length of follow-up: 24 months Number (N) of participants randomised to each arm: 21 in the treatment arm, 22 in the control arm Number (N) of participants analysed (primary outcome) in each arm: 19 in the treatment arm, 20 in the control arm		
Participants	<i>Population</i> : acute STEMI reperfused within 12 hours by PCI <i>Age, mean (SD) each arm</i> : 55 (SEM 1.6) years in treatment arm, 58.6 (SEM 2.5) years in control arm <i>Sex, % male in each arm</i> : 100% in treatment arm, 86.4% in control arm		
	Number of diseased vessels: 1 (42.9%), 2 (19.0%), 3(38.1%) in treatment arm, 1 (50%), 2 (18.2%), 3 (31.8%) in control arm Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: 17.1 (SEM 0.6) days from reperfusion to infusion of cells Statistically significant baseline imbalances between the groups?: none		
Interventions	Intervention arm: BM-MSC Type of stem cells: bone marrow-derived mesenchymal stromal cells (MSC) Summary of how stem cells were isolated and type and route of delivery: bone marrow (80 mL in 2000 II of heparin) was harvested from each patient in the treatment group from the posterior iliac crest un-		

Stem cell treatment for acute myocardial infarction (Review)

Gao 2013 (Continued)	
	der local anaesthesia by a haematologist 2 to 3 days after primary PCI. The bone marrow aspirate was shipped at room temperature to the central cell-processing laboratory. The mononuclear cell fraction was isolated using a density gradient with Lymphocyte Separation Medium (Biowhittaker) and then the low-density cells were washed and viable cells were counted. The BM-MCs were seeded into 75 cm <sup>2</sup> tissue culture flasks in MSCs medium consisting of Dulbecco's modified Eagle's medium containing 4.5% glucose (DMEM-4.5, HyClone), supplemented with 10% fetal bovine serum (GIBCO) and 1% an- tibiotic-antimycotic solution (Lift Technologies). The cell suspension was removed after 72 hours and the adherent cells were cultured in at 37 °C with 5% CO <sub>2</sub> . The culture medium was changed every 3 to 4 days until colonies were formed. After 14.6 ± 0.7 days of culture, passage 2 (P2) cells were harvested by trypsin treatment. Cells were washed, and viability was tested by trypan blue exclusion. Cell counts were performed, and the cells at 4 °C were delivered to the catheterisation laboratory. Cell were re-sus- pended in heparinised saline <i>Dose of stem cells</i> : 3.08 (± 0.52) x 10 <sup>6</sup> cells <i>Timing of stem cell procedure</i> : 16 to 17 days after PCI. Time from reperfusion to infusion of study thera- py = 17.1 (SEM 0.6) days
	Comparator arm: no additional therapy (control)
Outcomes	<i>Primary outcomes</i> : absolute changes in myocardial viability and perfusion in the infarcted region mea- sured by F-18-FDGi SPECT at 6 months, and in global LVEF measured by 2D echocardiogram at 6, 12 and 24 months after cell infusion <i>Secondary outcomes</i> : incidence of cardiovascular events, total mortality and adverse events at 12 and 24 months follow-up <i>Outcome assessment points</i> :6, 12, 24 months <i>Method(s)</i> : echocardiography, F-18-FDG SPECT
Notes	_

### **Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Participants were randomised 1:1 to treatment or control using sequential numbers
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported
Blinding (performance bias and detection bias) All outcomes	High risk	The trial was described as "open label". Controls did not undergo bone mar- row aspiration; no placebo was administered to controls. Echocardiography data were analysed independently by 2 experienced observers who were un- aware of patients' treatment assignment
Incomplete outcome data (attrition bias) All outcomes	Low risk	1 participant (1/22) in the control arm was lost to follow-up at 6 months and 1 patient (1/21) in the BMSC arm had died at 6 months follow-up; all other ran- domised participants were included in the analysis of clinical and scientific outcomes at 6 months. 2 further participants (1 in each treatment group) were lost to follow-up at 12 and 24 months' follow-up
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

Bias	Authors' judgement Support for judgement

Stem cell treatment for acute myocardial infarction (Review)

### Grajek 2010 (Continued)

Random sequence genera- tion (selection bias)	Low risk	Patients were assigned to the BMSC or control group by means of restricted randomisation (permuted blocks randomisation). The block size was 6 and the number of block was chosen using a computer random number generator. Patients having numbers 1 to 4 were allocated to the treatment group, whereas patients having numbers 5 or 6 were allocated to the control group (2:1 ratio)
Allocation concealment (selection bias)	Unclear risk	Prepared envelopes with treatment assignment were used; it is unclear whether these were sealed or opaque
Blinding (performance bias and detection bias) All outcomes	High risk	The study was "not blinded for the patients"; controls did not undergo bone marrow aspiration and no placebo was administered. Investigators assessing outcome measures were blinded to the group assignment
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical and scien- tific outcomes at 6 months. At 12 months, there were 4/31 withdrawals in the BMSC arm (1 sudden death at 7 months, 3 patients revascularised between 6 and 12 months) and 2/14 withdrawals in the control arm (2 patients revascu- larised between 6 and 12 months)
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	High risk	Supported in part by commercial funding

### Hirsch 2011

<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : Interuniversity Cardiology Institute of The Netherlands (ICIN), the Netherlands Heart Foundation (grant 2005T101, 2003B126), Biotronik, Boston Scientific, Guerbet, Guidant, Medtronic, No vartis, Pfizer, Sanofi-Aventis
<i>Country of origin</i> : the Netherlands <i>Number of centres</i> : 8
Dates of trial enrolment: 08/05 to 04/08 Length of follow-up: 5 years
Number (N) of participants randomised to each arm: 69 in treatment arm/65 in control arm Number (N) of participants analysed (primary outcome) in each arm: 67 in treatment arm/60 in control arm
<i>Population</i> : first STEMI. PCI with stent within 12 hours <i>Age, mean (SD) each arm</i> : 56 (9) years in treatment arm, 55 (10) years in control arm <i>Sex, % male in each arm</i> : 84% in treatment arm, 86% in control arm
Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: 53.3 (19.6)% dysfunctional segments in treatment arm/56.2 (24.7)% dysfunctional segments in control arm Time from symptom onset to initial treatment: median 3.5 (IQR 2.4 to 5.1) hours in treatment arm/medi- an 3.4 (IQR 2.3 to 4.2) hours in control arm Statistically significant baseline imbalances between the groups?: none reported
Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: 60 mL BM aspirated from iliac crest under local anaesthesia, collected in a sterile container with heparin, sent to 1 of 6 cell-processin labs. MNC isolated by density gradient centrifugation using LymphoprepTM, washed twice and re-sus-

Stem cell treatment for acute myocardial infarction (Review)

Risk of bias	
Notes	3 patients did not receive cell therapy as randomised: 1 withdrew consent, 1 aspiration was unsuccess- ful and 1 patient experienced an occluded infarct-related artery
	<i>Method</i> (s): MRI, angiogram
	Outcome assessment points: baseline, 4 months, 2 years, 5 years
	<i>Secondary outcomes</i> : "changes in absolute segmental wall thickening in dysfunctional segments, changes in global LVEF, volumes, mass, and infarct size, and changes in regional myocardial function stratified by transmural extent of infarction."
Outcomes	<i>Primary outcomes</i> : "The change in regional myocardial function in dysfunctional segments at baseline defined as the percentage of dysfunctional segments with improved segmental wall thickening at 4 months"
	Comparator arm: no additional therapy (control)
lirsch 2011 (Continued)	pended in 15 to 20 mL saline with 4% human serum albumin and 20 IU/mL sodium heparin. Cells were infused into the infarct-related artery through the central lumen of an over-the-wire balloon catheter in 3 sessions of 3 minutes of coronary occlusion, interrupted by 3 minutes of coronary flow <i>Dose of stem cells</i> : total 296 (164) x 10 <sup>6</sup> BMMNC <i>Timing of stem cell procedure</i> : cells infused 3 to 8 days after primary PCI (median 6 days)

Authors' judgement	Support for judgement
Low risk	Permuted block randomisation was performed with stratification according to site, with the use of a computerised voice-response system
Unclear risk	Allocation concealment was not reported
High risk	Controls did not undergo bone marrow aspiration and no placebo was admin- istered. "After randomisation, study processes were not blinded"
Low risk	All randomised participants were included in the analysis of clinical outcomes at 4 months, with the exception of 1 patient in the BMSC group who withdrew consent. In the analysis of MRI data at 4 months, 1 further patient in the BMSC group (total 2/69) and 5 patients in the control group (5/65) withdrew or were excluded due to poor quality MRI (1 BMSC patient and 3 controls), 1 control patient who received and implanted ICD, and 1 control patient who refused follow-up. At 2 years follow-up, a total of 10/69 BMSC patients and 13/65 con- trol patients were withdrawn or excluded from MRI analysis; reasons were giv- en. In the analysis of clinical outcomes at 5 years, 9 patients (BMSC: 4/69 ver- sus controls: 5/65) were lost to follow-up
Unclear risk	All outcomes mentioned in the study design protocol are reported apart from exercise tolerance, which was included as a secondary outcome
High risk	Supported in part by commercial funding
	Low risk Unclear risk Low risk Unclear risk Unclear risk

	<i>Dose of stem cells</i> : mean 402 (196) x 10 <sup>6</sup> mononuclear cells injected (median = 360 x 10 <sup>6</sup> ) of which a mean of 2.6 (1.6) x 10 <sup>6</sup> <i>Timing of stem cell procedure</i> : the time interval between the AMI and cell transfer was 70 (36) hours (median 60 hours) in BMMNC arm
	Comparator arm: placebo medium containing the same solution as cell medium without the cells
Outcomes	<i>Primary outcomes</i> : (1) Absolute change in global LVEF from baseline to 6 months. (2) Absolute changes in the measures obtained by IVUS. (3) Changes in arrhythmia risk variables from baseline to 6 months
	Secondary outcomes: exercise stress test
	Outcome assessment points: baseline and 6 months
	<i>Method(s)</i> : 2-D echocardiography, LV angiography, IVUS, ECG
Notes	_

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Randomisation codes for each patient were generated by a laboratory nurse in Ouluusing using "a computer-generated random-permuted block design with variable block sizes and selected on the basis of whether a suspension con- taining BMCs or placebo medium was given to each patient". The laboratory nurse in Turku was informed by a telephone call from Oulu about the randomi- sation and type of treatment
Allocation concealment (selection bias)	Low risk	The laboratory nurse in Turku was informed by a telephone call from Oulu about the randomisation and type of treatment. The lab nurses who prepared the treatment or placebo solution according to patient allocation did not take part in any other parts of the research protocol
Blinding (performance bias and detection bias) All outcomes	Low risk	All patients had bone marrow aspiration and control group patients were giv- en an intracoronary injection of placebo medium. The treatment and control media were externally prepared by laboratory nurses. Blinded outcome as- sessors not involved in randomisation quantitatively analysed angiograms, echocardiograms and intravascular ultrasounds in a central core laboratory. Consecutively numbered, sealed envelopes were provided and stored in the Clinical Research Laboratory of the University of Oulu and were opened after all baseline and 6-month data were analysed from all patients
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical outcomes. In the analysis of scientific outcomes by echocardiography at 6-month fol- low-up, the number of withdrawals was low in both trial arms (1 patient in each treatment arm due to refusal from repeat testing and 1 death in the placebo arm). Further withdrawals from LV angiography were low and bal- anced between treatment groups (BMSC: 4/40 versus placebo: 4:40). Analysis by IVUS incurred a higher number of withdrawals but these were balanced be- tween treatment arms (BMSC: 28/40 versus placebo: 30/40)
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00363324) were reported
Other bias	High risk	Supported in part by commercial funding

anssens 2006			
Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : Fund of Scientific Research Flanders		
	Country of origin: Belgi Number of centres: 1	um	
Participants	<i>Population</i> : AMI, within 24 to 48 hours <i>Age, mean (SD) each arm</i> : 55.8 (11) years in treatment arm, 57.9 (10) years in control arm <i>Sex, % male in each arm</i> : 82% in treatment arm, 82% in control arm		
	Number of diseased vessels: 1 in treatment arm (36% right artery/64% left artery)/1 in control arm (38% right artery/62% left artery) Number of stunned hyperkinetic, etc segments: 3 or more contiguous segments out of total 17 Time from symptom onset to initial treatment: 3.7 hours (median) before PCI in treatment arm/4.1 hours (median) before PCI in control arm Statistically significant baseline imbalances between the groups?: none		
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirated, cell separated using gradient centrifugation. 4 to 6 hours after harvest, cells were washed and re-susper ed in 10 mL of saline containing 0.9% NaCl and 5% autologous serum. Intracoronary infusion using inflated balloon catheter. 3 fractions of cells were infused over 2 to 3-minute periods separated by 3 minute reperfusion Dose of stem cells: 10 mL of cell suspension, a total dose of 3.0 (1.28) x 108 nucleated cells containin 1.72 (0.72) x 108 MNC Timing of stem cell procedure: PCI was performed about 4 hours after onset of symptoms. Cell treat- ment was conducted within 1 day of PCI		
	<i>Comparator arm</i> : placebo consisting of 10 mL of saline containing 0.9% NaCl and 5% autologous serum		
Outcomes	Primary outcomes: changes in LVEF at 4 months Secondary outcomes: changes in: 1. infarct size 2. LV function		
	<i>Outcome assessment points</i> : baseline, 4 and 12 months. <i>Method(s)</i> : MRI		
Notes	This trial includes some patients with previous AMI, but data analysis without these patients did not significantly change the final results		
Risk of bias			
Bias	Authors' judgement	Support for judgement	
Random sequence genera- tion (selection bias)	Low risk	A computerised randomisation list was used

Stem cell treatment for acute myocardial infarction (Review)

Janssens 2006	(Continued)
---------------	-------------

Blinding (performance bias and detection bias) All outcomes	Low risk	The trial was described as "double blind". All patients underwent bone marrow aspiration and control group patients were given an intracoronary injection of placebo medium. Outcome assessors were blinded to treatment
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical outcomes. In the analysis of scientific outcomes measured by MRI at 4 and 12 months, the number of withdrawals was low and balanced between trial arms (BMSC: 3/33 versus control: 4/34). Reasons for withdrawal were 1 x technical failure, 2 x claustrophobia to MRI, 2 x patient refusal, 1 x intracochlear implant and 1 death in the BMSC arm due to haemorrhagic shock)
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00264316) were reported
Other bias	Low risk	None reported or identified

## Jazi 2012

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : not reported				
	Country of origin: Iran Number of centres: 1				
	Dates of trial enrolment: 06/02 to 01/04 Length of follow-up: 6 months Number (N) of participants randomised to each arm: not reported Number (N) of participants analysed (primary outcome) in each arm: 16 in the treatment arm, 16 in the control arm				
Participants	<i>Population</i> : AMI within 1 month with a history of anterior MI and LVEF < 35% <i>Age, mean (SD) each arm</i> : 48.0 (SEM 2.5) years in treatment arm, 45.2 (SEM 3.2) years in control arm <i>Sex, % male in each arm</i> : 66% in treatment arm, 90% in control arm				
	Number of diseased vessels: 1 Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: up to 1 month Statistically significant baseline imbalances between the groups?: none				
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirates were obtained under local anaesthesia with a standard Jamshidi needle with heparin (50 U/mL) from pos- terior iliac crests. Bone marrow-derived mononuclear cells (BMCs) were isolated by layering on a Fi- coll-Paque gradient. Cell populations included hematopoietic progenitor cells. A haemocytometer was used to estimate the number of nucleated cells in the final preparation of bone marrow cells. Nu- cleated cell viability was assessed by trypan blue exclusion. Nucleated cells were cultured in an M199 medium, 10% human serum supplemented with 50 ng/mL vascular endothelial growth factor (VEGF), 1 ng/mL basic fibroblast growth factor (bFGF), and 2 ng/mL insulin-like growth factor-1 (IGF-1). The cells were incubated overnight at 37 °C in a fully humidified atmosphere with 5% CO <sub>2</sub> . Then, cells were				
	washed twice and re-suspended in 5 mL human serum <i>Dose of stem cells</i> : (24.6 ± SEM 8.4) × 10 <sup>8</sup> cells				
	Timing of stem cell procedure: within 1 month of AMI, at the time of PCI				
	Comparator arm: no additional therapy (control)

#### Lee 2014

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : funded by PCB-Pharmicell Company Limited (Seongnam, Korea)
	<i>Country of origin</i> : South Korea <i>Number of centres</i> : 3
	Dates of trial enrolment: 03/07 to 09/10 Length of follow-up: 6 months Number (N) of participants randomised to each arm: 40 in the treatment arm, 40 in the control arm Number (N) of participants analysed (primary outcome) in each arm: 30 in the treatment arm, 28 in the control arm
Participants	<i>Population</i> : AMI within 96 hours <i>Age, mean (SD) each arm</i> : 53.9 (10.5) years in treatment arm, 54.2 (7.7) years in control arm <i>Sex, % male in each arm</i> : 90.0% in treatment arm, 89.3% in control arm
	Number of diseased vessels: 1 (n = 16), 2 (n = 11), 3 (n = 3) in treatment arm, 1 (n = 16), 2 (n = 8), 3 (n = 4) in control arm Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: 350.8 (325.4) minutes in treatment arm, 115.3 (35.5) min- utes in control arm Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BM-MSC Type of stem cells: bone marrow-derived mesenchymal stromal cells Summary of how stem cells were isolated and type and route of delivery: 20 to 25 mL (mean ± SD: 23.1 ±1 1.5 mL) of BM aspirates were obtained under local anaesthesia from the posterior iliac crest in the treatment group on 3.8 ± 1.5 days after admission. All manufacturing and product testing procedures for the generation of clinical-grade autologous MSCs were carried out under good manufacturing prac- tice (FCB-Pharmicell Company Limited, Seongnam, Korea). Mononuclear cells were separated from the BM by density gradient centrifugation (HISTOPAQUE-1077; Sigma-Aldrich, St. Louis, MO, USA) and washed with phosphate-buffered saline (PBS). Cells were re-suspended in Dulbecco's modified Eagle's medium-low glucose (DMEM; Gibco, Grand Island, NY, USA) containing 10% fetal bovine serum (Gib- co), 100 U/mL penicillin/100 µg/mL and streptomycin (Gibco). They were plated at 2 to 3 × 10 <sup>5</sup> cells/ cm <sup>2</sup> into 75 cm <sup>2</sup> flasks. Cultures were maintained at 37 °C in a humidified atmosphere containing 5% CO <sub>2</sub> . After 5 to 7 days, non-adherent cells were removed by replacing the medium; adherent cells were cultured for another 2 to 3 days. When the cultures were near confluence (70% to 80%), adherent cells were detached by using trypsin containing ethylene diamine tetra-acetic acid (EDTA; Gibco) and replat ed at 4 to 5 × 10 <sup>3</sup> cells/cm <sup>2</sup> in 175 cm <sup>2</sup> flasks. Cells were serially subcultured up to passage 4 or passage 5 for infusion (mean ± SD: 4.4 ± 0.5 passages). On the day of administration, MSCs were harvested us- ing trypsin and EDTA, washed twice with PBS and once with saline solution, and re-suspended to a fi- nal concentration of 1 × 10 <sup>6</sup> cells/kg. The criteria for the release of MSCs for clinical use included viabil- ity > 80%, absence of microbial contamination (bacteria, fungus, virus and mycoplasma) if undertaken 3 to 4 days before administration, and expression of CD73 and CD105 by > 90% of cells and absence o

Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: BM aspirates 6 days (median, range 5 to 6 days) after PCI were separated by Ficoll gradient centrifugation and re-suspended in he- parinised plasma prior to transplantation. Intracoronary infusion using an inflated balloon catheter. Dose of stem cells: a single dose of 0.68 x 108 MNC (median, range 0.54 to 1.3 x 10 <sup>8</sup> MNC) containing 0.7 x 10 <sup>6</sup> CD34 <sup>+</sup> cells (median, range 0.4 to 1.6 x 10 <sup>6</sup> CD34 <sup>+</sup> cells) Timing of stem cell procedure: 4 to 8 days after primary PCI. Median 6 days (interquartile range 5 to 6) Comparator arm: no additional therapy (control)				
Outcomes	<i>Primary outcomes</i> : changes in LVEF (%) measured by SPECT, echocardiography and MRI <i>Secondary outcomes</i> : changes in LVEDV (mL) and infarcted size. Also reported: NYHA class, quality of life, exercise tolerance				
	<i>Outcome assessment points</i> : baseline, 3, 6, 12, 36 months <i>Method(s)</i> : echocardiography, SPECT and MRI, SF-36, electrically braked bicycle ergometer				
Notes	Three patients did not receive cell therapy as randomised: 1 patient had low cell viability and 2 patients had stent thrombosis in the acute phase				
Risk of bias					
Bias	Authors' judgement	Support for judgement			
Random sequence genera- tion (selection bias)	Low risk	Randomisation was generated by permuted blocks stratified according to cen- tre			
Allocation concealment (selection bias)	Low risk	Randomisation details were provided in consecutively numbered, sealed envelopes			
Blinding (performance bias and detection bias) All outcomes	High risk	Controls did not undergo bone marrow aspiration and no placebo was admin- istered; neither participants nor patients were blinded. Echocardiograms and angiograms were analysed by investigators blinded to treatment allocation			

Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00199823) were reported
Other bias	Low risk	None reported or identified

Stem cell treatment for acute myocardial infarction (Review)

	<i>Country of origin</i> : Czech <i>Number of centres</i> : 1	n Republic		
	arms and the control g Number (N) of participa	months <i>ints randomised to each arm</i> : not reported (73 in total across both intervention		
Participants	Population: AMI, within 24 hours Age, mean (SD) each arm: 54 (SEM 2) years in the high cell dose group, 54 (SEM 2) years in the low cell dose group, and 55 (SEM 2) years in control Sex, % male in each arm: 90% in the high cell dose group, 95% in the low dose group, and 90% in con- trols			
	Number of diseased vessels: 1:14, 2:6, 3:0 (high dose); 1:11, 2:8, 3:1 (low dose); 1:14, 2:6, 3:0 in control Number of stunned hyperkinetic, etc segments: 0.4 (0.2) (high dose), 0.5 (0.2) (low dose), 0.4 (0.2) (con- trols). Irreversibly damaged segments: 6.2 (SEM 0.6) (high dose), 5.9 (SEM 0.5) (low dose), 6.1 (SEM 0.5) (controls) Time from symptom onset to initial treatment: 444 minutes (SEM 163 minutes) (high dose), 401 minutes (SEM 133 minutes) (low dose), 552 minutes (SEM 204 minutes) (controls) Statistically significant baseline imbalances between the groups?: none			
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: BM aspirates after PCI. Cells were separated by density centrifugation. Cells cultivated overnight and re-suspended in 22 mL prior to transplantation. Intracoronary infusion using an inflated balloon catheter. 7 balloon inflations for 3 minutes each, separated by 3-minute intervals of balloon deflation. 3 mL BM cell suspension injected at each balloon deflation Dose of stem cells: 1 x 10 <sup>8</sup> MNC (range 0.9 to 2 x 10 <sup>8</sup> cells) (high dose) or 1 x 10 <sup>7</sup> MNC (range 0.9 to 2 x 10 <sup>7</sup> cells) (low dose) Timing of stem cell procedure: PCI within 24 hour of AMI symptoms, 3 to 7 days for randomisation, 5 to 9 days BM aspiration and infusion. Time from onset to cell transplantation: 6.8 (0.3) days (high dose) and 6.9 (0.3) days (low dose)			
	Comparator arm: no additional therapy (control)			
Outcomes	<i>Primary outcomes</i> : change in regional systolic function of the infarcted wall <i>Secondary outcomes</i> : changes in 1. LVEF, 2. LV volumes, 3. Perfusion defect size <i>Outcome assessment points</i> : baseline and 3, 6 and 12 months			
	Method(s): SPECT and E			
Notes	Data from the 2 active intervention arms of the trial are pooled in this review. 2 patients had fever and 1 patient had brachycardia, all within 20 hours prior to cells; these 3 patients were randomised to cell therapy (unclear whether high or low dose) but they did not receive cell therapy as randomised			
Risk of bias				
Bias	Authors' judgement	Support for judgement		
Random sequence genera- tion (selection bias)	Unclear risk	The trial was described as randomised but the method of randomisation was not reported		
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported		

Meluzin 2008 (Continued)		
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding of participants and clinicians was not reported although controls did not undergo bone marrow aspiration and no placebo was administered. Echocardiographers were blinded to treatment assignment
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	From a total of 73 patients randomised to 1 of 3 treatment arms, 7 withdrew or were excluded from the analysis of all outcomes: 1 control patient was exclud- ed because PET did not confirm the irreversibility of the myocardial damage and 2 controls underwent repeat MI 2 days after the hospital discharge due to in-stent thrombosis. 3 patients randomised to BMSC were not transplanted because of complications within 20 hours before the procedure and a 4th pa- tient was excluded because of an inadequate amount of implanted MBM cells; it was unclear whether these patients were randomised to high or low-dose BMSC. 4 patients (cells: 2/22 versus no cells: 2/22) were missing from SPECT analysis at 3 and 12 months follow-up; reasons for missing data were not re- ported. In separate publications, an expanded cohort of up to 73 patients (37 high dose cells and 36 controls) were included in SPECT analysis at 3, 6 and 12 months; the number of randomised patients was unclear
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

# Nogueira 2009

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : supported by Pro-Cardiaco Hospital - in charge of patients' care - and by Exellion Biomedical Services S/A - in charge of cell preparation and characterisation		
	Country of origin: Brazil Number of centres: 2		
	Dates of trial enrolment: 01/05 to 01/06 Length of follow-up: 6 months Number (N) of participants randomised to each arm: 14 in intracoronary artery route (AG) arm, 0 in in- tracoronary venous route (VG) arm, 6 in control arm Number (N) of participants analysed (primary outcome) in each arm: 14 in AG arm, 8 in VG arm, 6 in con- trol arm		
Participants	<i>Population</i> : AMI, within 24 hours. Thrombolysis and/or PCI within 24 hours <i>Age, mean (SD) each arm</i> : 59.7 (14.3) years in AG arm, 53.6 (8.3) years in VG arm, 57.2 (10.8) years in con trol arm <i>Sex, % male in each arm</i> : 71% in AG arm, 70% in VG arm, 67% in control arm		
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment:		
	AG group: 29% < 12 hours, 21% > 12 hours, 50% > 6 hours and after thrombolysis (all within 24 hours)		
	VG group: 20% < 12 hours, 20% > 12 hours, 60% > 6 hours and after thrombolysis (all within 24 hours)		
	Control group: 50% > 12 hours, 33% > 6 hours and after thrombolysis (all within 24 hours) Statistically significant baseline imbalances between the groups?: none		
Interventions	<i>Intervention arm</i> : BMMNC (coronary artery route, AG or coronary venous route, VG) <i>Type of stem cells</i> : bone marrow-derived stem cells (mononuclear cells-MNC)		

Stem cell treatment for acute myocardial infarction (Review)

Nogueira 2009 (Continued)			
	Summary of how stem cells were isolated and type and route of delivery: approx. 80 mL bone marrow as- pirated from the posterior iliac crest under sedation, analgesia and local anaesthesia. MNC were iso- lated and centrifuged in a Ficoll-Pacque Plus and handled under aseptic conditions. The cells were washed and suspended in saline solution with 5% human serum albumin, re-suspended and filtered to remove cell aggregates prior to transplantation. Arterial delivery via over-the-wire balloon catheter PCI. Venous delivery via an additional over-the-wire balloon catheter positioned side-by-side with the bal- loon in the artery where the stent was located <i>Dose of stem cells</i> : 10 mL of solution containing 100 x 10 <sup>6</sup> MNC <i>Timing of stem cell procedure</i> : the time interval between the AMI and cell transfer was 5.5 (1.28) days (AG) and 6.1 (1.37) days (VG)		
	Comparator arm: no additional therapy (control)		
Outcomes	Primary outcomes: LVEF, WMSI, EDV, ESV		
	Secondary outcomes: radiolabeled cells retention and washout in the heart tissue		
	Outcome assessment points: baseline, 3 and 6 months		
	<i>Method(s)</i> : echocardiography, RNV		
Notes	Data from the 2 active intervention arms of the trial are pooled in this review		
Risk of bias			
Bias	Authors' judgement	Support for judgement	
Random sequence genera- tion (selection bias)	Low risk	Random assignment was made in blocks according to the AMI size (≤ 25% or < 25%), by means of sealed envelopes. Random allocation was stratified accord- ing to infarct size in 3 blocks of different size, for each stratum, with the use of sealed envelopes	
Allocation concealment (selection bias)	Low risk	Randomisation details were provided in sealed envelopes	

Blinding (performance bias and detection bias) All outcomes	High risk	Controls did not undergo bone marrow aspiration and no placebo was admin- istered. Outcome assessors were blinded. Blinding of participants and clini- cians not reported. The trial was described as "open-label in relation to the clinical analysis and blind in relation to the echocardiographic analysis"
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants in the control group were included in the analy- sis of clinical outcomes and scientific outcomes. 2 patients in the intravenous cell group were missing from echocardiographic analysis at 3 and 6 months follow-up (1 sudden death 1 month after cell therapy, 1 tortuous anterior inter- ventricular vein complicating BMSC transfer)
Selective reporting (re- porting bias)	High risk	The secondary outcomes of QoL, Seattle Angina Questionnaire and cost-effec- tiveness described in the trial protocol (www.clinicaltrials.gov: NCT00350766) were not reported
Other bias	High risk	Supported in part by commercial funding

# Penicka 2007

Methods

*Type of study*: parallel RCT *Type of publication*: full *Source of funding*: Research Grant from Charles University of Prague

Stem cell treatment for acute myocardial infarction (Review)

Penicka 2007 (Continued)	<i>Country of origin</i> : Czech Republic <i>Number of centres</i> : not reported
	Dates of trial enrolment: not reported Length of follow-up: 24 months Number (N) of participants randomised to each arm: 17 in the treatment arm/10 in the control arm Number (N) of participants analysed (primary outcome) in each arm: 14 in the treatment arm/10 in the control arm
Participants	<i>Population</i> : AMI, within 24 hours <i>Age, mean (SD) each arm</i> : 61 (14) in treatment arm, 54 (10) in control arm <i>Sex, % male in each arm</i> : 71% in treatment arm, 100% in control arm
	Number of diseased vessels: not stated clearly, but assumed 1, left anterior descendent (LAD) Number of stunned hyperkinetic, etc segments: at least 3 akinetics segments in the LAD artery Time from symptom onset to initial treatment: time from onset of AMI to PCI, median 315 (range 300 to 600) days in BMSC arm, median 330 (range 300 to 630) days in control arm Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirations took place 4 to 11 (median 8) days following PCI. Cells were isolated following the protocol described by Wollert 2004. Infusion of cells in the LAD artery Dose of stem cells: a single dose of 26.4 x 10 <sup>8</sup> (median) mononuclear cells Timing of stem cell procedure: PCI carried out 4 to 11 hours after onset of AMI, cell infusion 4 to 11 days following PCI
	Comparator arm: no additional therapy (control)
Outcomes	<i>Primary outcomes</i> : not reported <i>Secondary outcomes</i> : changes in 1. LVEF, 2. LVEDV (mL), 3. LVESV (mL), 4. Infarct size. Also measured: NYHA class, QOL
	<i>Outcome assessment points</i> : baseline, 4, 12 and 24 months <i>Method(s)</i> : echocardiography and SPECT (infarct size), SF-36
Notes	2 patients originally assigned to the treatment group did not receive active treatment because of com- plications which occurred before the planned cell transfer. Both patients died during early follow-up. The trial had originally intended to recruit 40 patients to the treatment arm and 20 to the control arm. Trial was prematurely stopped after 27 enrolled " <i>because of the unexpected occurrence of serious com-</i> <i>plications in the BMSC group and no incremental functional effects of BMSCs as compared with control</i> <i>patients</i> "

**Risk of bias** 

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Unclear risk	The trial was described as randomised but the method of randomisation was not reported
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding of participants and clinicians was not reported although controls did not undergo bone marrow aspiration and no placebo was administered. Echocardiography specialists were blinded to patient group assignment
Incomplete outcome data (attrition bias)	Low risk	All randomised participants were included in the analysis of clinical outcomes 3 patients in the BMSC group (3/17) died prior to echocardiography follow-up

Stem cell treatment for acute myocardial infarction (Review)

Penicka 2007 (Continued) All outcomes		(1 in-stent thrombosis with reinfarction immediately after BMSC harvest - had a complicated PCI followed by CABG and died 2 weeks later from sepsis and ARDS, 1 ventricular rupture before BMSC injection, underwent emergency surgery and died 3 months later due to severe heart failure and 1 received BMSCs and was diagnosed with biliary carcinoma 6 weeks after BMSC infusion and died 2 months later). All patients in the control group were included in echocardiography analysis at all follow-up time points up to 2 years
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	High risk	Trial was intending to recruit 40 participants in the intervention group and 20 in the control group. The trial was prematurely stopped after 27 participants were enrolled "because of the unexpected occurrence of serious complications in the BMSC group and no incremental functional effects of BMSC as compared with control patients"

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : supported by Azienda USL di Piacenza and Fondazione Piacenza & Vigevano
	Country of origin: Italy Number of centres: 1
	Dates of trial enrolment: 07/05 to 06/07 Length of follow-up: 24 months Number (N) of participants randomised to each arm: 19 in treatment arm/19 in control arm Number (N) of participants analysed (primary outcome) in each arm: 17 in treatment arm, 15 in control arm
Participants	<i>Population</i> : AMI, within 6 hours. PCI within 2 to 6 hours of onset of symptoms <i>Age, mean (SD) each arm</i> : 63.1 (SEM 2.7) years in treatment arm, 67.2 (SEM 2.4) years in control arm <i>Sex, % male in each arm</i> : 68.4% in treatment arm, 68.4% in control arm
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: 248 (SEM 68.7) minutes from AMI to PCI in treatment arm; 265 (SEM 34.4) minutes from AMI to PCI in treatment arm Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: 100 mL of autologous bone marrow was aspirated under local the posterior-superior iliac crest by multiple aspirations into he- parinised syringes. The cells were suspended in 7 mL of PBS-EDTA buffer containing 3 mL of human albumin 5% W/V. Mononuclear cell fraction was concentrated into a final volume of 25 to 30 mL. Bal- loon catheter was positioned at the site of the former infarct-vessel occlusion and PCI performed 4 to 5 times, for 2 minutes each time. During this time intracoronary cell transplantation via the balloon catheter was performed, using 4 to 5 fractional high-pressure infusions of 2 to 3 mL of the cell suspen- sion Dose of stem cells: mononuclear cells: mean 248.78 x 10 <sup>6</sup> were infused (minimum 75.4 x 10 <sup>6</sup> ; maximum 570.0 x 10 <sup>6</sup> ) Timing of stem cell procedure: 4 to 7 days after AMI
	Comparator arm: no additional therapy (control)

Stem cell treatment for acute myocardial infarction (Review)

	Dates of trial enrolment: "between 2005 - 2007" Length of follow-up: 2 years Number (N) of participants randomised to each arm: 40 in treatment arm/20 in control arm Number (N) of participants analysed (primary outcome) in each arm: 38 in treatment arm, 18 in control arm
Participants	<i>Population</i> : AMI, within 12 hours. PCI within 12 hours of onset of symptoms <i>Age, mean (SD) each arm</i> : 59 (9) years in treatment arm, 56 (8) years in control arm <i>Sex, % male in each arm</i> : 68% in treatment arm, 78% in control arm

Stem cell treatment for acute myocardial infarction (Review)

Plewka 2009 (Continued)	<i>Time from symptom on</i> from AMI to PCI in cont	<i>verkinetic, etc segments</i> : not reported <i>set to initial treatment</i> : 7(2) hours from AMI to PCI in treatment arm; 8(3) hours
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: 100 mL bone marrow aspirated from the iliac crest using local anaesthesia. Bone marrow aspirates were diluted with 20 mL of 0.9% Na- Cl, filtrated, and mononuclear cells were isolated by density gradient centrifugation, washed twice with 0.9% NaCl, filtered, and subjected to quality and quantity control. Intracoronary infusion by PCI over the wire balloon catheter technique. Dose of stem cells: 1.44 (0.49) x 10 <sup>8</sup> MNC and 3.06 (2.18) x 10 <sup>6</sup> CD34 <sup>+</sup> cells Timing of stem cell procedure: bone marrow was aspirated 7 (SD = 2) days (range 3 to 11 days) after STEMI, the cell suspension was administrated within 2 hours of bone marrow harvest Comparator arm: no additional therapy (control)	
Outcomes	<i>Primary outcomes</i> : LVEF, LVEDV, LVESV, WMSI <i>Secondary outcomes</i> : systolic myocardial velocity S, 2-dimensional strain, 2-dimensional strain in in- farcted area, mitral inflow E/A, early filling propagation velocity, early diastolic myocardial velocity, transmitral flow velocity/annular velocity ratio (E/E) <i>Outcome assessment points</i> : baseline, 6, 12 and 24 months	
Notes	Method(s): echocardiography, 2-D systolic strain, G-SPECT —	
Risk of bias		
Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Unclear risk	The trial was described as randomised but the method of randomisation was not reported
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported
Blinding (performance bias and detection bias) All outcomes	High risk	Blinding of participants and clinicians was not reported although controls did not undergo bone marrow aspiration and no placebo was administered. Inde- pendent blinded investigators collected and analysed echocardiographic data; SPECT perfusion images were analysed quantitatively by a single investigator blinded to all other data
Incomplete outcome data (attrition bias) All outcomes	High risk	This study was initially reported in 2 separate publications with partial patient overlap (30 patients were included in both publications; both studies included patients which were missing from the other). In one publication, all 60 randomised participants were included in the analysis of clinical outcomes. At 6-month follow-up, 4 patients had died: 2/40 in the BMSC arm (1 fatal STEMI and 1 sudden cardiac death during the 6 months follow-up) and 2/20 in the control arm (2 sudden cardiac deaths during the 6-month follow-up) and were not included in echocardiography analysis at 6 months and subsequent follow-up at 1 and 2 years. In the second publication of 39 randomised patients, 3 controls (3/13) were missing from SPECT analysis at 6 months (1 death at 5 months, 2 failed to attend follow-up visit)

Stem cell treatment for acute myocardial infarction (Review)

# Quyyumi 2011 (Continued)

# Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Unclear risk	The trial was described as randomised but the method of randomisation was not reported
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported
Blinding (performance bias and detection bias) All outcomes	High risk	The trial was described as "open label". Controls did not undergo bone mar- row aspiration and no placebo was administered; neither participants nor pa- tients were blinded. However, "all studies were analysed by operators blinded to the patient treatment designation"
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	1 patient in the high-dose arm was excluded due to acute stent thrombosis soon after cell infusion. All other randomised patients were included in the analysis of clinical outcomes. For MRI assessment at 3 and 6 months, 1 patient had died due to ventricular fibrillation soon after cell infusion. 2 further pa- tients in the high-dose BMSC group (total 4/6), 1 patient in the medium-dose BMSC arm (1/5) and 5 patients in the control group (5/15) were missing from MRI assessment. There were no withdrawals or exclusions (0/5) in the low- dose BMSC group. The reasons for patient drop-out were given as "death, re- fused, defibrillators, stent thrombosis, and poor image quality", however the number of patients falling into each category was not reported
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00313339) were reported
Other bias	High risk	This is a commercially funded trial

### Roncalli 2010

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full
	<i>Source of funding</i> : French Department of Health - Programme Hospitalier de Recherche Clinique (PHRC), the Association Francaise contre les Myopathies, the Fondation de France
	<i>Country of origin</i> : France <i>Number of centres</i> : 6
	Dates of trial enrolment: 12/04 to 01/07 Length of follow-up: 12 months Number (N) of participants randomised to each arm: 52 in treatment arm/49 in control arm Number (N) of participants analysed (primary outcome) in each arm: 48 in BMSC arm/44 in control arm
Participants	<i>Population</i> : acute STEMI, PCI with stent within 24 hours <i>Age, mean (SD) each arm</i> : 56 (12) years in treatment arm, 55 (11) years in control arm <i>Sex, % male in each arm</i> : 80.8% in treatment arm, 89.8% in control arm
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: "within 24h after the onset of chest pain"; < 12 hours in 75% of BMSC arm/75.5% of control arm Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMMNC

Stem cell treatment for acute myocardial infarction (Review)

Risk of bias	
Notes	1 patient did not receive BM aspirate due to thrombopenia but was included as randomised
	<i>Method</i> (s): radionuclide angiography (RNA), echocardiography, MRI, T201-SPECT, MLHFQ
	Outcome assessment points: baseline, 1 month, 3 months, 12 months
	<i>Secondary outcomes</i> : 1. changes in LVEF evaluated by RNA, MRI, and echocardiography, 2. changes in LVEDV and LVESV, 3. infarct size by MRI, 4. binary restenosis by coronary angiography, 5. segment-by-segment improvement of myocardial viability. Also measured: QOL
Outcomes	<i>Primary outcomes</i> : improvement of myocardial viability - "a gain of at least 2/17 viable segments 3 months after STEMI, assessed by resting 4 h thallium-201-gated-SPECT."
	Comparator arm: no additional therapy (control)
	<i>Timing of stem cell procedure</i> : infusion performed 9.3 ± 1.7 days after AMI
	tioned within the stented segment <i>Dose of stem cell</i> s: 100 x 10 <sup>6</sup> autologous BMMNC
	er progenitor cells, as well as mononuclear cells. A single syringe of 100 x 10 <sup>6</sup> BMCs was prepared in 10 mL 4% human albumin. Intracoronary infusion using over-the-wire balloon catheter technique positive dwithin the started escenant.
	tion medium centrifugation procedures were used to isolate and enrich progenitor cells. A heteroge- neous cell suspension population was obtained that consisted of haematopoietic, endothelial and oth-
	Summary of how stem cells were isolated and type and route of delivery: 50 mL of bone marrow was as- pirated into heparinised syringes under local anaesthesia from the iliac crest. Lymphocyte prepara-
	Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC)
Roncalli 2010 (Continued)	<i>Type of stem cells</i> : bone marrow-derived stem cells (mononuclear cells-MNC)

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Patients were randomly assigned in a 1:1 ratio to either the control group or BMC group using permuted-block randomisation stratified according to centre, diabetes status and time to PCI after the onset of AMI (≤ 12 or > 12 hours)
Allocation concealment (selection bias)	Low risk	Consecutively numbered, sealed envelopes were provided to all participant centres
Blinding (performance bias and detection bias) All outcomes	High risk	The trial was described as "open label"; controls did not undergo bone mar- row aspiration and no placebo was administered; neither participants nor pa- tients were blinded. 3 independent core imaging laboratories, blinded to treat- ment assignment, performed all cardiac imaging measurements
Incomplete outcome data (attrition bias) All outcomes	Low risk	In the analysis of clinical outcomes, there were 9 withdrawals or exclusions: 4/52 in the BMSC arm (2 withdrawals due to adverse clinical events, 1 with- drawal due to randomisation error and 1 refusal to complete follow-up) and 5/49 in the control arm (1 patient had steroid therapy for angioneurotic oede- ma, 1 had post-MI ventricular septal defect and 3 patients refused follow-up). In the analysis of scientific outcomes at 3 months, 1 further patient in the BMSC arm had died and 1 additional patient in the control arm was missing, the reason for which was not reported
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00200707) were reported
Other bias	Low risk	None reported or identified

Methods	<i>Type of study</i> : parallel RCT
	<i>Type of publication</i> : full
	Source of funding: not reported
	Country of origin: China
	Number of centres: 1
	Dates of trial enrolment: 07/03 to 08/04
	<i>Length of follow-up</i> : 6 months
	Number (N) of participants randomised to each arm: 9 in the BMSC arm/11 in the control arm
	<i>Number (N) of participants analysed (primary outcome) in each arm</i> : 9 in the BMSC arm/11 in the contro arm
Participants	Population: AMI, within 24 hours
	<i>Age, mean (SD) each arm</i> : 61 (8) years in treatment arm, 58 (6) years in control arm
	Sex, % male in each arm: 88.9% in treatment arm, 100% in control arm
	Number of diseased vessels: range 1 to 3 but no more details stated
	Number of stunned hyperkinetic, etc segments: not reported
	<i>Time from symptom onset to initial treatment</i> : 12.7 (12.6) hours in treatment arm/12.3 (13.4) hours in
	control arm
	Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMMNC
	<i>Type of stem cells</i> : bone marrow-derived stem cells (mononuclear cells-MNC)
	Summary of how stem cells were isolated and type and route of delivery: the study does not state how
	the cells were isolated or processed. Except that cells were suspended in diluted serum prior to trans-
	plantation. Cells were infused by percutaneous transmural coronary angioplasty (PTCA)
	Dose of stem cells: not reported
	Timing of stem cell procedure: within 2 hours of successful PTCA
	Comparator arm: diluted serum
Outcomes	Primary outcomes: the study does not state clearly a primary outcome. The aim is to assess changes in
	LV segmental function by Doppler imaging
	Secondary outcomes: changes in 1. LV global function and volume, 2. LVEDV (mL), 3. LVESV (mL), 4. LVE (%)
	Outcome assessment points: baseline, 3 months and 6 months
	<i>Method(s)</i> : Doppler imaging and echocardiography
Notes	

**Risk of bias** 

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	High risk	This Chinese trial was described as randomised; patients were selected "prospectively and consecutively"
Allocation concealment (selection bias)	High risk	Allocation concealment was not reported
Blinding (performance bias and detection bias) All outcomes	Unclear risk	The control group received an injection of heparinised saline although it is not reported whether they underwent bone marrow aspiration. It is therefore un- clear whether participants and clinicians were sufficiently blinded to treat- ment. Outcome assessors were blinded to clinical and angiographic informa- tion

Stem cell treatment for acute myocardial infarction (Review)

### Ruan 2005 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical and scien- tific outcomes
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

chachinger 2006	
Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : research grant from Guidant and support from Eli Lilly
	<i>Country of origin</i> : Germany and Switzerland <i>Number of centres</i> : 17 (16 in Germany + 1 in Switzerland)
	Dates of trial enrolment: 04/04 to 04/05 Length of follow-up: 5 years Number (N) of participants randomised to each arm: 101 in the treatment arm/103 in control arm Number (N) of participants analysed (primary outcome) in each arm: 95 in treatment arm/92 in control arm
Participants	<i>Population</i> : AMI, within 5 days <i>Age, mean (SD) each arm</i> : 55 (11) years in treatment arm, 57 (11) years in control arm <i>Sex, % male in each arm</i> : 82% in treatment arm, 82% in control arm
	Number of diseased vessels: 1:61; 2:24; 3:16 in treatment arm/1:60; 2:32; 3:11 in control arm Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: 7.5 (8.0) hours to PCI in treatment arm/7.0(6.5) hours to PCI in control arm Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: BM aspirates 3 to 6 days after PCI, cells were separated by Ficoll gradient centrifugation and re-suspended in 10 mL of X-VIVO medi- um containing 20% autologous serum. Intracoronary infusion using an inflated balloon catheter. 3 por- tions of 3.3 mL cell suspension were infused in 3-minute occlusion time for each portion and 3-minute intervals Dose of stem cells: 10 mL of a single dose containing 2.36 (1.74) x 10 <sup>8</sup> mononuclear cells Timing of stem cell procedure: PCI within 12 hrs of AMI symptoms, harvest 3 to 6 days after PCI, ran- domisation and transport prior to infusion 3 to 6 days
	Comparator arm: placebo consisting of 10 mL X-VIVO medium with 20% autologous serum
Outcomes	<i>Primary outcomes</i> : changes in LVEF <i>Secondary outcomes</i> : 1. Improvement of global LVEF, 2. Reduction of LVESV, 3. Improvement of region- al wall motion and myocardial contractility, 4. Assessment of major adverse events, such as revascular- isation, death and hospitalisation due to heart failure
	<i>Outcome assessment points</i> : baseline, 4, 12, 24 months, 5 years <i>Method(s)</i> : LV angiography
Notes	3 patients randomised to the placebo arm did not receive placebo medium but were included in the analysis: 1 patient in placebo group had angiographic evidence of a thrombus in a non-infarct-relat-

Stem cell treatment for acute myocardial infarction (Review)

Schachinger 2006 (Continued)

ed artery, 1 patient had an air embolism during initial angiography before the guidewire could be advanced and in 1 patient the guidewire could not be advanced into the infarct-related artery

**Risk of bias** 

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Randomisation was carried out using computer-generated randomised lists maintained at a site external to the trial
Allocation concealment (selection bias)	Low risk	Bone marrow aspirates were sent to the cell processing centre (centralisation)
Blinding (performance bias and detection bias) All outcomes	Low risk	All patients underwent bone marrow aspiration and control group patients were given an intracoronary injection of placebo medium. Bone marrow aspi- rates were then sent to a central cell processing centre; participants and clini- cians were therefore blinded to treatment. LV angiography was performed by an experienced investigator in a central core laboratory who was unaware of the patient's treatment assignment until after analysis of 4-month data was complete. Study centres and investigators and those entering the data into databases remained blinded until 12-month follow-up was complete.
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised patients were included in the analysis of clinical outcomes at 4 months follow-up; 3 and 2 patients in the control group were lost to follow-up at 12 months and 2 years respectively. In the analysis of scientific outcomes, 6/101 in the BMSC group and 11/103 in the placebo group were missing from LV angiography analysis at 4 months (2 had poor quality results on angiography, 4 deaths before 4 months, 5 declined and 6 did not undergo angiography). A subset of 59 patients were included in a sub-study of MRI 2 years
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00279175) were reported, with the exception of NYHA class, although all other pre-specified morbidity outcomes were reported
Other bias	High risk	This is a commercially funded trial

#### Suarez de Lezo 2007

Trusted evidence. Informed decisions. Better health.

Sürder 2013 (Continued)		
	<i>Country of origin</i> : Switzerland <i>Number of centres</i> : 4	
	Dates of trial enrolment: 10/06 to 01/12 Length of follow-up: 4 months Number (N) of participants randomised to each arm: 66 in the early cell therapy arm, 67 in the late cell therapy arm, 67 in the control arm Number (N) of participants analysed (primary outcome) in each arm: 58 in the early cell therapy arm, 49 in the late cell therapy arm, 60 in the control arm	
Participants	Population: STEMI with PCI in 24 hours and EF ≤ 45% Age, mean (SD) each arm: median 55 (IQR 15) years (early cells), 62 (IQR 15) years (late cells), 56 (IQR 14.5) years (controls) Sex, % male in each arm: 86.2% (early cells), 82.5% (late cells), 83.6% (controls)	
	Number of diseased vessels: 1 (54%), 2 (32%), 3 (14%) (early cells), (57%), 2 (27%), 3 (16%) (late cells), 1 (64%), 2 (21%), 3 (15%) (controls) Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: 6 (2) days (early cells) or 24 (7) days (late cells) after AMI Statistically significant baseline imbalances between the groups? Higher age in the late treatment group compared with controls (median 62 years versus 56 years; P value = 0.06); lower percentage of smokers in the late treatment group compared with controls (40.3% versus 62.7%; P value = 0.01); higher base- line LVEF in the control group compared with the treatment group (median 39.6% versus 35.6%, P val- ue = 0.03)	
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: bone marrow aspiration was performed 5 to 7 days after AMI. Between 60 and 80 mL of bone marrow was collected from the iliac crest under local anaesthesia. Then 1 mL of a solution containing 1000 IU heparin was added to each 10 mL of bone marrow aspirate to prevent clotting. Then the aspirate and 20 mL of the patient's serum were sent at room temperature by courier to the cell-processing centre. The BM-MNC cell suspension was shipped back to the participating hospital within 24 hours. Briefly, with the use of density gradi- ent centrifugation, the mononuclear cell fraction was re-suspended in 10 mL of serum-free medium with 20% of autologous serum added without any additional heparin. An aliquot of cell suspension was utilised for fluorescence-activated cell sorting analysis with the use of fluorochrome conjugated anti- bodies against anti-human CD34 and CD133; cell viability was assessed by 7-AAD cell uptake, and steril- ity was assessed by the Bact/Alert rapid method. Release criteria of the BMMNC were product sterility, a cell count between 5 × 10 <sup>7</sup> and 5 × 10 <sup>8</sup> , and cell viability of ≥ 80% Dose of stem cells: 1.59 (± 1.25) × 10 <sup>8</sup> cells (early cells); 1.39 (± 1.20) × 10 <sup>8</sup> cells (late cells) Timing of stem cell procedure: 5 to 7 days post-AMI (early cells); 3 to 4 weeks post-AMI (late cells)	
Outcomes	Comparator arm: no additional therapy (control)  Primary outcomes: absolute change in global LVEF from baseline to 4 months Secondary outcomes: change in LVEF, LVESV, LVEDV infarct size proportion of scar mass to total LV mass, global and regional myocardial thickening, major adverse events Outcome assessment points: 4 and 12 months Method(s): MRI	
Notes	Data from the 2 active intervention arms of the trial are pooled in this review. There is a discrepancy be tween the absolute change LVEF values and baseline/endpoint values reported. The authors were con- tacted to request clarification on this discrepancy but none was forthcoming	
Risk of bias		
Bias	Authors' judgement Support for judgement	
Random sequence genera- tion (selection bias)	Low risk Randomisation was performed using closed envelopes in a 1:1:1 pattern	

Stem cell treatment for acute myocardial infarction (Review)

# Sürder 2013 (Continued)

Allocation concealment (selection bias)	Low risk	Closed envelopes were used
Blinding (performance bias and detection bias) All outcomes	High risk	The trial was described as "open label"; controls did not undergo bone mar- row aspiration and no placebo was administered; neither participants nor pa- tients were blinded. However, it is reported that "the entire analysis was per- formed in a CMR core laboratory, blinded to the treatment assignment of the patients enrolled."
Incomplete outcome data (attrition bias) All outcomes	High risk	In the analysis of clinical outcomes, the number of withdrawals and exclusions was unbalanced between groups (early cells: 11/66 versus late cells: 15/67 versus control: 7/67). Although reasons for withdrawals were given (withdrawal of informed consent or death in all missing patients), these do not fully explain the sample sizes described in individual analyses. In the analysis of scientific outcomes by MRI analysis at 4 months, 8 additional patients were missing in the BMSC arm due to the lack of paired MRI data
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00355186) were reported
Other bias	Low risk	None reported or identified

### Tendera 2009

Methods	Type of study: parallel RCT Type of publication: full Source of funding: Polish Ministry of Science and Higher Education (grants number PBZ-KBN-099/ P05/2003, 0651/P01/2007/32, 2422/P01/2007/32)
	<i>Country of origin</i> : Poland <i>Number of centres</i> : 5
	Dates of trial enrolment: 03/05 to 09/07 Length of follow-up: 6 years Number (N) of participants randomised to each arm: 80 (selected cells), 80 (unselected cells), 40 (con- trols) Number (N) of participants analysed (primary outcome) in each arm: 51 (selected cells), 46 (unselected cells), 20 (controls)
Participants	<i>Population</i> : AMI, within 12 hours. PCI within 12 hours <i>Age, mean (SD) each arm</i> : median 58 years (selected cells), 55 years (unselected cells), 59 years (con- trols) <i>Sex, % male in each arm</i> : 63.7% (selected cells), 70.6% (unselected cells), 75% (controls)
	Number of diseased vessels: 1 in all trial arms Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: from AMI to PCI: median 303 minutes (101 to 1100) (se- lected cells), 309 minutes (117 to 1000) (unselected cells), 300 minutes (120 to 1080) (controls) Statistically significant baseline imbalances between the groups?: none
Interventions	<i>Intervention arm</i> : CD34 <sup>+</sup> CXCR4 <sup>+</sup> or BMMNC <i>Type of stem cells</i> : selected cells: CD34 <sup>+</sup> CXCR4 <sup>+</sup> selected bone marrow-derived stem cells; unselected cells: bone marrow-derived stem cells (mononuclear cells-MNC)
	Summary of how stem cells were isolated and type and route of delivery: 100 to 120 mL bone marrow as- pirated from the posterior superior iliac spine into heparinised syringes under general anaesthesia

Tendera 2009 (Continued)	
(	Selected cells: Ficoll density gradient centrifugation to isolate mononuclear cells, CD34 <sup>+</sup> CXCR4 <sup>+</sup> cell population was isolated using two-step immunomagnetic selection with monoclonal antibodies cou- pled with magnetic beads and MidiMACS System. Re-suspended in phosphate-buffered saline (final vol- ume 10 mL). Delivery via intracoronary infusion by PCI over the wire balloon catheter technique
	Unselected cells: Ficoll density gradient centrifugation to isolate mononuclear cells. Delivery via intra- coronary infusion by PCI over the wire balloon catheter technique <i>Dose of stem cells</i> : 3 infusions delivering a median of 1.9 x 10 <sup>6</sup> CD34 <sup>+</sup> CXCR4 <sup>+</sup> cells in total (selected cells); median of 1.78 x 10 <sup>8</sup> MNCs (unselected cells) <i>Timing of stem cell procedure</i> : BM aspiration and BMSC infusion was done 7 (3 to 12) (median (range)) days after primary PCI.
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: LVEF by MRI Secondary outcomes: LVEF by LV angiography, LVESV, LVEDV, MACE (death, re-infarction, stroke and tar- get vessel revascularisation (TVR)) Outcome assessment points: baseline, 6 months, 6 years Method(s): echocardiogram, LV angiography, MRI
Notes	Data from the 2 active intervention arms of the trial are pooled in this review. Table 1 footnote says values expressed as medians with quartiles, whereas text describes means and ranges - unclear whether values throughout paper for medians are whole ranges or interquartile ranges

#### **Risk of bias**

Bias Authors' judgement Support for judgement		Support for judgement	
Random sequence genera- tion (selection bias)	Unclear risk	"Eligible patients were randomised by centre in 2:2:1 fashion into three paral- lel groups" but the sequence generation procedure was not described	
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported	
Blinding (performance bias and detection bias) All outcomes	High risk	The trial was described as "open label"; controls did not undergo bone mar- row aspiration and no placebo was administered. Investigators assessing cMRI and LV angiography outcome measures were blinded to the group assignment	
Incomplete outcome data (attrition bias) All outcomes	High risk	All randomised participants were included in the analysis of clinical outcomes. For MRI assessment at 6 months follow-up, there was 29/80 missing in selected BMSC arm (1 death, 28 unexplained), 34/80 missing in unselected BMSC arm (1 death, 33 unexplained), and 20/40 missing in control arm (1 death, 19 unex- plained)	
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00316381) were reported, although LVEF and LV volumes were measured by MRI and LV angiography rather than echocardiography	
Other bias	Low risk	None reported or identified	

### Traverse 2010

Methods

*Type of study*: parallel RCT *Type of publication*: full *Source of funding*: the Jon Holden DeHaan Foundation, The Production Assistance for Cellular Therapies, N01-HB-37164

Traverse 2010 (Continued)	
	Country of origin: USA Number of centres: 1
	Dates of trial enrolment: "beginning in 12/05" Length of follow-up: 6 months Number (N) of participants randomised to each arm: 30 in treatment arm/10 in control arm Number (N) of participants analysed (primary outcome) in each arm: 30 in treatment arm/10 in control arm
Participants	<i>Population</i> : first anterior STEMI, PCI with stent implantation <i>Age, mean (SD) each arm</i> : median 52.5 years (IQR = 43, 64) in treatment arm, median 57.5 years (IQR = 54, 59) in control arm <i>Sex, % male in each arm</i> : 83.33% in treatment arm, 60% in control arm
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: median 4.6 hours (IQR = 2, 12 hours) in treatment arm/ median 2.9 hours (IQR = 2.8, 10.6 hours) in control arm Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: patients lightly sedated, 50 to 70 mL bone marrow aspirated from posterior iliac crest. Aspirate heparinised and transported within 1 hour to cell therapy laboratory. BMMNC isolated by Ficoll density centrifugation at 450 g, cells counted with an automated cell counter and the cell suspension volume was adjusted to reach a final product of 100 million BMCs with 5% human serum albumin in 20 mL. Administered via intracoronary perfusion Dose of stem cells: 10 <sup>8</sup> BMSC Timing of stem cell procedure: median 4.5 days (IQR = 4,7 days) after PCI, within 8 hours of BM aspira- tion
	<i>Comparator arm</i> : solution of 0.9% isotonic sodium chloride solution and 5% human serum albumin in an identical volume
Outcomes	Primary outcomes: "To investigate the effects of BMC administration in patients following STEMI on re- covery of LV function using cardiac MRI" Secondary outcomes: LV volumes by MRI, safety as assessed by MACE (death, repeated target vessel revascularisation, recurrent MI, hospitalisation for chronic heart failure, and internal cardia defibrilla- tor (ICD) placement) Outcome assessment points: baseline and 6 months Method(s): MRI
Notes	_
Risk of bias	

Risk	of	bias

Bias	Authors' judgement	Support for judgement	
Random sequence genera- tion (selection bias)	Low risk	Randomisation was based on an algorithm developed by a biostatistician	
Allocation concealment (selection bias)	Low risk	Randomisation was performed at the cell processing facility following prepa- ration of the bone marrow cells	
Blinding (performance bias and detection bias) All outcomes	Low risk	The trial was described as "double blind"; all patients underwent bone mar- row aspiration and control group patients were given an intracoronary injec- tion of placebo medium. Blinding of clinicians was not reported. Outcome measurements were assessed by MRI readers blinded to treatment allocation	

Stem cell treatment for acute myocardial infarction (Review)

# Traverse 2010 (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical and scien- tific outcomes
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00268307) were reported, with the exception of infarct size which was in- cluded as a secondary outcome
Other bias	Low risk	None reported or identified

#### Traverse 2011

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : supported by the National Heart, Lung, and Blood Institute
	Country of origin: USA Number of centres: 5
	Dates of trial enrolment: 07/08 to 02/11 Length of follow-up: 6 months Number (N) of participants randomised to each arm: 59 in the treatment arm, 29 in the control arm Number (N) of participants analysed (primary outcome) in each arm: 55 in the treatment arm, 26 in the control arm
Participants	<i>Population</i> : AMI within 2 to 3 weeks after PCI <i>Age, mean (SD) each arm</i> :57.6 (11) in the treatment arm, 54.6 (11) in the control arm <i>Sex, % male in each arm</i> : 79% in the treatment arm, 90% in the control arm
	Number of diseased vessels: 1 or 2 or 3 Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: median 3.4 (IQR 2.3 to 14.3) hours from onset to PCI; me- dian 17.4 (IQR 15.5 to 20.0) days from PCI to infusion Statistically significant baseline imbalances between the groups? Baseline heart rate at initial presenta- tion was higher in the placebo group than the treatment group (90.3% versus 77.5%; P value = 0.01)
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived mononuclear cells (MNC) Summary of how stem cells were isolated and type and route of delivery: approximately 80 to 90 mL of bone marrow was aspirated from the iliac crest using standard techniques. The aspirate was processed at all sites with a closed, automated cell processing system (Sepax, Biosafe SA) to ensure a uniform cel- lular product. After BMC enrichment, cells were washed 3 times and suspended in 5% human serum al- bumin/saline solution. The composition of CD34 and CD133 cells was determined by fluorescent acti- vated cell sorting Dose of stem cells: 1.47 (± 1.7) x 10 <sup>8</sup> cells Timing of stem cell procedure: median (IQR) 17.4 (15.5 to 20.0) days after PCI
	Comparator arm: placebo (0.9% saline and 5% human serum albumin)
Outcomes	<i>Primary outcomes</i> : 1. change in global LV function, 2. change in regional function by wall motion in the infarct and border zones <i>Secondary outcomes</i> : composite measure of major adverse clinical events, LV mass, LVEDV, LVESV, infarct size <i>Outcome assessment points</i> : 6 months <i>Method(s)</i> : cardiac MRI

### Traverse 2011 (Continued)

Notes

1 patient in the BMSC group did not receive treatment due to a new 90% stenosis in the left main artery before cell infusion but was included in the analysis as randomised

**Risk of bias** 

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Patients were randomly assigned to one to the selected treatment strategies using an interactive web-based randomisation session in a 2:1 ratio using ran- domly selected block sizes of 6 or 9 and stratified by centre
Allocation concealment (selection bias)	Low risk	Randomisation was performed by the data co-ordinating centre. Treatment assignment was masked to all but one designated cell processing team mem- ber at each of the 5 centres who was not involved in patient care
Blinding (performance bias and detection bias) All outcomes	Low risk	All patients underwent bone marrow aspiration and control group patients were given an intracoronary injection of placebo medium. Patients and re- search staff, including the CCTRN physicians and interventional cardiologists, were blinded to treatment assignment. The MRI core laboratory was blinded to study group assignment
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical outcomes. 6 patients (BMSC: 3/58 versus placebo: 3/29) were not included in MRI analy- sis at 6 months. In the placebo group, 1 patient experienced acute pancreati- tis at 3 months and in 2 patients, MRI was contraindicated due to a new ICD. In the BMSC group, 1 patient did not receive cells due to severe LMS stenosis and 2 patients did not attend the 6-month follow-up visit
Selective reporting (re- porting bias)	Low risk	All outcomes described in the trial protocol (www.clinicaltrials.gov: NCT00684060) were reported
Other bias	Low risk	None reported or identified

	Country of origin: Italy Number of centres: 1
	Dates of trial enrolment: 03/04 to 02/06 Length of follow-up: 12 months Number (N) of participants randomised to each arm: 15 in single cell transfer arm (ST), 15 in repeated cell transfer arm (RT) and 15 in control arm Number (N) of participants analysed (primary outcome) in each arm: 12 (ST), 15 (RT), 12 (controls)
Participants	<i>Population</i> : AMI, within 12 hours. <i>Age, mean (SD) each arm</i> : 52.1 (6.3) years in ST arm, 51.3 (7.4) years in RT arm, 52.7 (7.8) years in control arm <i>Sex, % male in each arm</i> : 83.3% in ST arm, 80.0% in RT arm, 91.7% control arm
	Number of diseased vessels:
	ST arm: 1 vessel disease = 4/12 (33.33%), 2 vessel disease 5/12 (41.67%), 3 vessel disease 3/12 (25.00%)
	RT arm: 1 vessel disease = 5/15 (33.33%), 2 vessel disease 6/15 (40.00%), 3 vessel disease 4/15 (26.67%)

Stem cell treatment for acute myocardial infarction (Review)

ao 2009 (Continued)			
	(25.00%) Number of stunned hyp Time from symptom on 6.0 (2.8) hours (control	ase = 3/12 (25.00%), 2 vessel disease 6/12 (50.00%), 3 vessel disease 3/12 perkinetic, etc segments: not reported uset to initial treatment: from AMI to PCI: 4.9 (2.9) hours (ST), 4.7(2.9) hours (RT), as) baseline imbalances between the groups?: none	
Interventions	Intervention arm: single BMMNC dose (SD) or repeated BMMNC dose (DD) Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: 90 ± 18 mL bone marrow was aspirated from the posterior superior iliac spine under local anaesthesia. Bone marrow aspirates were diluted with 0.9% NaCl (1:5) and mononuclear cells were isolated by density gradient centrifugation, washed 3 times with PBS and then suspended in 16 mL heparin-treated plasma at a density of (1.3 ± 1.0) × 10 <sup>7</sup> cells/mL at room temperature. Cell transplantation via intracoronary route using an over-th wire balloon catheter inserted into the stent that was implanted during primary PCI. Procedure repea ed at 3 months in repeated cell dose arm Dose of stem cells: mean 1.9 (SE 1.2) × 10 <sup>8</sup> BMC (ST), 2.0 (SE 1.4) × 10 <sup>8</sup> (RT, first delivery), 2.1 (SE 1.7) × 10 <sup>8</sup> (RT, second delivery at 3 months) Timing of stem cell procedure: BMC infusion 3 to 7 days after PCI, and 3 hours after BMC collection, fol- lowed by saline infusion (ST group) or second infusion (RT group) 3 months after PCI Comparator arm: saline infusion 3 to 7 days after PCI (no secondary infusion at 3 months)		
Outcomes	Primary outcomes: LVEF, LVEDV, LVESV		
		nyocardial infarct area, myocardial perfusion defect, survival, re-hospitalisation ilure, serious adverse events	
	Outcome assessment points: baseline, 6 and 12 months		
	Method(s): MRI, SPECT, LV angiography		
Notes	Data from the 2 active intervention arms of the trial are pooled in this review. 3 patients randomised to single dose BMSC were not transplanted as follows: 1 patient could not undergo MRI due to pacemaker implantation following development of bradycardia, 1 patient developed a fever 12 hours prior to the procedure, and in 1 patient an inadequate amount of cells was acquired		
Risk of bias			
Bias	Authors' judgement	Support for judgement	
Random sequence genera- tion (selection bias)	Low risk	Randomisation was undertaken using a computer-generated random number sequence	

Allocation concealment (selection bias)	Low risk	Sequentially numbered, sealed, opaque envelopes were used
Blinding (performance bias and detection bias) All outcomes	High risk	Although the control group received a placebo, only the active treatment groups (single or double dose) underwent BM aspiration. Further, the active treatment groups were recalled for the second infusion of cells or placebo whereas the control group was not recalled for further treatment. Participants were therefore not appropriately blinded. Blinding of clinicians was not re- ported. MRI and SPECT studies were processed and evaluated at the MRI and scintigraphy core laboratories respectively by experienced operators who were blinded to the assigned therapy
Incomplete outcome data (attrition bias) All outcomes	Low risk	All patients in the repeat BMSC arm were included in the analysis of all out- comes. 3 patients in the single BMSC arm and 3 patients in the control arm (3/15) were withdrawn or excluded from the analysis of all outcomes. In the BMSC arm, 1 patient developed a fever 12 hours prior to the procedure, for one

Stem cell treatment for acute myocardial infarction (Review)

Yao 2009 (Continued)		patient an inadequate amount of cells was acquired and one patient could not undergo MRI due to pacemaker implantation following development of bradycardia. In the control arm, 1 patient had a reinfarction 5 days after dis- charge due to in-stent thrombosis, 1 patient was excluded due to diagnosis of liver cancer at 4 months, and 1 patient could not be contacted at 3 months follow-up. One additional patient in the control group was missing from MRI analysis at 12 months follow-up.
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

Methods	<i>Type of study</i> : parallel RCT
	Type of publication: full
	Source of funding: the "135" Major Research Subject for Medical Talent of Jiangsu Province (No.
	RC2003092); the Social Technical Developing Item of Scientific Bureau of Wuxi City (No. CS040001)
	<i>Country of origin</i> : Wuxi, Jiangsu Province, China <i>Number of centres</i> : 1
	Dates of trial enrolment: 10/03 to 06/05
	Length of follow-up: 8 weeks
	Number (N) of participants randomised to each arm: 7 in treatment arm/16 in control arm
	<i>Number (N) of participants analysed (primary outcome) in each arm</i> : 7 in treatment arm/16 in control arm
Participants	Population: thrombolysis within 24 hours
	Age, mean (SD) each arm: 60.5 years in treatment arm, 62.5 years in control arm
	Sex, % male in each arm: 71.4% in treatment arm, 56.3% in control arm
	Number of diseased vessels: not reported
	Number of stunned hyperkinetic, etc segments: not reported
	Time from symptom onset to initial treatment: thrombolysis within 24 hours of AMI symptom onset
	Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMMNC
	<i>Type of stem cells</i> : bone marrow-derived stem cells (mesenchymal stem cells)
	Summary of how stem cells were isolated and type and route of delivery: 25 mL bone marrow was as-
	pirated from the superior anterior iliac spine. Aspirate washed and centrifuged to isolate MNC layer.
	This was cultured in DMEM for a week and passaged 3 times. The cultured cells were harvested and sus
	pended in solution. Infused via the femoral artery PCI route into the left and right coronary arteries
	Dose of stem cells: 5 mL suspension, 1.5 x 10 <sup>10</sup> BMSC/L for a total of 7.5 x 10 <sup>7</sup> cells delivered <i>Timing of stem cell procedure</i> : 14 days after AMI
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: none
	<i>Secondary outcomes</i> : LVEF, CO, infarct area <i>Outcome assessment points</i> : baseline, 2, 4, 6 and 8 weeks
	Method(s): echocardiography, Sopha PET-CT (radionuclide imaging)
Notes	Translated from Chinese (Mandarin)
Risk of bias	

#### You 2008 (Continued)

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Low risk	Random numbers were assigned via a table
Allocation concealment (selection bias)	Unclear risk	Allocation concealment was not reported
Blinding (performance bias and detection bias) All outcomes	High risk	The trial was described as a "single-blind" evaluation. Controls did not under- go bone marrow aspiration and no placebo was administered; neither partic- ipants nor clinicians were blinded. The first author designed, carried out, col- lected data and assessed the results
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical and scien- tific outcomes
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

### Zhukova 2009

Methods	<i>Type of study</i> : parallel RCT <i>Type of publication</i> : full <i>Source of funding</i> : not reported			
	<i>Country of origin</i> : Russia <i>Number of centres</i> : 1			
	Dates of trial enrolment: not reported Length of follow-up: 36 months Number (N) of participants randomised to each arm: 8 in treatment arm/3 in control arm Number (N) of participants analysed (primary outcome) in each arm: 8 at 1 year, 6 at 3 years in treatment arm/2 at 1 year, 1 at 3 years in control arm			
Participants	<i>Population</i> : MI of the front wall and low EF (< 38%). Males with systolic dysfunction who had successful reperfusion therapy (thrombolysis and/or urgent angioplasty) <i>Age, mean (SD) each arm</i> : 48 (7) years in treatment arm, 50 (10) years in control arm <i>Sex, % male in each arm</i> : 100% in treatment arm/100% in control arm			
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: PCI within 6.5 (3) hours of AMI in treatment arm/PCI with- in 6.2 (2) hours of AMI in control arm Statistically significant baseline imbalances between the groups?: none			
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: 50 to 80 mL bone marrow was aspirated and centrifuged to obtain the mononuclear cells. These were re-suspended into autologous patient serum Dose of stem cells: 2 to 5 mL portions for a total of 20 mL; 5 x 10 <sup>6</sup> BMMNC Timing of stem cell procedure: 14 to 19 days after AMI			
	Comparator arm: no additional therapy (control)			

Stem cell treatment for acute myocardial infarction (Review)

#### Zhukova 2009 (Continued)

Outcomes	Primary outcomes: none Secondary outcomes: mortality, morbidity, QOL, LVEF, LVEDV, LVESV, perfusion defect, myocardial via- bility Outcome assessment points: baseline, 3, 6, 12, 24 and 36 months Method(s): echocardiography, SPECT, gadolinium-based MRI
	bility <i>Outcome assessment points</i> : baseline, 3, 6, 12, 24 and 36 months

Notes

Translated from Russian

**Risk of bias** 

Bias	Authors' judgement	Support for judgement
Random sequence genera- tion (selection bias)	Unclear risk	The trial was described as randomised but the method of randomisation was not reported
Allocation concealment (selection bias)	Unclear risk	The use of envelopes was mentioned, but insufficient detail was provided to establish whether appropriate allocation concealment was used
Blinding (performance bias and detection bias) All outcomes	High risk	Controls did not undergo bone marrow aspiration and no placebo was admin- istered; neither participants nor clinicians were blinded. Blinding of outcome assessors was not reported
Incomplete outcome data (attrition bias) All outcomes	Low risk	All randomised participants were included in the analysis of clinical outcomes and of scientific outcomes at 3 months. In MRI and echocardiographic analysis at 12 months follow-up, 1 control patient had died, and at 3 years follow-up 1 further control and 2 patients in the BMSC group had died
Selective reporting (re- porting bias)	Unclear risk	All outcomes mentioned in the methods were reported in the results, although it would be difficult to rule out selective reporting
Other bias	Low risk	None reported or identified

#### Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion	
Ang 2008	A RCT of BMSC in patients with chronic coronary artery disease	
Arnesen 2007	A commentary on RCTs of cell therapy in MI	
Atsma 2008	An ongoing single-arm trial investigating mesenchymal stem cell therapy after acute MI	

Stem cell treatment for acute myocardial infarction (Review)

Copyright  ${\ensuremath{\mathbb C}}$  2015 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.

Study	Reason for exclusion
Beeres 2007	A single-arm trial of autologous BMSC in patients with chronic MI
Benedek 2014	A RCT of BMMNC versus placebo in patients with MI. This study was excluded because MI occurred up to 3 months prior to study enrollment and was therefore not classified as AMI
Chen 2004a	Stem cells were not removed and then reinfused, rather stem cells were mobilised following G-CSF
Chen 2014	A RCT of G-CSF mobilised peripheral blood stem cells versus placebo in patients with AMI. The con- trol group did not receive G-CSF
Engelmann 2006	A RCT of G-CSF mobilised PBSC (no cells administered) compared with placebo in patients with sub-acute MI
EUCTR 2010-020497-41-GB	An ongoing trial of allogeneic mesenchymal precursor cells versus placebo in patients with AMI
Fernandez 2004	A comparison of CD34+ cell infusion with a non-randomised control group in patients with AMI
Gyongyosi 2009	A RCT of BMMNC administration either 2 to 3 weeks or 3 to 4 months post AMI. This study did not in- clude a control group
Hare 2007	The trial used allogeneic (not autologous) mesenchymal stem cells, therefore was not eligible for inclusion in the review
Heeger 2012	A non-randomised study of BMMNC compared with a matched control group in patients with AMI
Hendrikx 2006	A RCT of BMSC compared with a control group in patients with chronic ischaemic heart disease un- dergoing CABG
Holinski 2011	A non-randomised trial of autologous BM cells in patients with chronic heart failure scheduled for elective CABG compared with a matched control group
Hu 2015	A RCT of normoxia BMMNC versus hypoxia-preconditioned BMMNC in patients with AMI. BMMNC groups were compared with a non-randomised control group
Jiang 2011	A systematic review of RCTs of BMSC in AMI
Kahn 2006	A summary of stem cell trials in MI presented at the 2nd International Conference on Cell Therapy for Cardiovascular Diseases
Kang 2004	A commentary on cell therapy trials in MI
Kang 2006	A RCT of infused G-CSF mobilised peripheral blood stem cells versus placebo in patients with AMI. The control group did not receive G-CSF
Kang 2007	A RCT of BMSC infusion compared with G-CSF compared with a control group in patients with AMI or old MI (OMI). Outcome data are not presented separately for the AMI and OMI groups
Kang 2008	A commentary on results from 2 trials of mobilised PBSC in patients with AMI
Kang 2011	A 3-arm trial design protocol of intravenous darbepoetin infusion and intracoronary infusion of G-CSF mobilised PBSC, G-CSF mobilised PBSC alone or standard medical treatment. The control group did not receive G-CSF
Li 2006	A RCT of infused G-CSF mobilised PBSC compared with no treatment in patients with AMI. The con- trol group did not receive G-CSF

Stem cell treatment for acute myocardial infarction (Review)

Study	Reason for exclusion
Li 2008	A RCT of the effect of MSC on vascular endothelial function in AMI patients. The outcomes of this study, published in full, are beyond the scope of this review
Lu 2012	An experimental animal study comparing MSC and control groups in MI-induced swine
Makkar 2012	A RCT of cardiosphere-derived cells compared with controls in patients with AMI
Marenzi 2007	A comment on the conclusions of the authors of the REPAIR-AMI trial
Messori 2013	A meta-regression analysis of 2 previously published meta-analyses of BMMNC in AMI
Mills 2007	An evaluation and commentary on the REPAIR-AMI trial
Musialek 2006	A RCT of 2 active interventions: over-the-wire balloon catheter for bone marrow stem cell delivery and cell infusion via a perfusion catheter with multiple side holes
Musialek 2010	A RCT of 2 active interventions: over-the-wire balloon catheter for bone marrow stem cell delivery and cell infusion via a perfusion catheter with multiple side holes
Nasseri 2013	A RCT of BMMNC versus CD133+ cells versus controls during CABG in patients enrolled 8 to 12 weeks after AMI
NCT00548613	A non-randomised trial cell therapy in patients with AMI, comparing intracoronary infusion with in- tramyocardial infusion of a cell mixture of BMSC and progenitor cells. This trial did not include a control group
NCT00874354	An ongoing trial investigating 2 different doses of BMSC in patients with AMI. This trial does not in- clude a control group
NCT00877903	A RCT of allogeneic ex vivo cultured adult human MSCs in patients with AMI
Nie 2007	A non-randomised trial of BMMNC compared with a control group in patients with AMI
Obradovic 2009	A non-randomised trial of BMSC compared with a control group in patients with AMI
Osterziel 2007	A comment on the conclusions of the authors of the REPAIR-AMI trial
Ott 2013	A RCT of G-CSF mobilised PBSC (no cell infusion) versus placebo in patients with AMI
Peruga 2009	A non-randomised trial of BMSC compared with a control group in patients with AMI
Schachinger 2004	A RCT of 2 active interventions: circulating progenitor cells and bone marrow-derived progenitor cells with no control comparator group
Schueller 2007	A non-randomised study of BMSC versus no cells in patients with AMI
Shrimahachota 2011	A RCT of BMSC compared with a control group with patients with AMI which occurred at a mean of 57.2 days and 45.3 days in the BMSC and control groups respectively
Taljaard 2010	An ongoing RCT of autologous endothelial-like culture-modified mononuclear cell infusion (E- CMMs) compared with both an active treatment arm receiving an infusion of autologous E-CMMs transfected with endothelial nitric oxide synthase and a control arm receiving standard therapy. Trial excluded as the mononuclear cells collected from circulating blood are not classified as BMSC
Terrovitis 2011	A RCT of intracoronarily administered G-CSF mobilised peripheral blood stem cells versus placebo in patients with AMI. The control group did not receive G-CSF

Stem cell treatment for acute myocardial infarction (Review)

Study	Reason for exclusion
Trzos 2009	A RCT of BMSC compared with a control group in patients with AMI. Excluded because this trial, published in full, evaluated heart rate variability which is not covered by the scope of this review
Vanderheyden 2007	A RCT of enriched haematopoietic BMSC therapy in patients with MI randomised to early or late cell therapy. This trial does not include a randomised control group
Wang 2006	A non-RCT of BMSC compared with a control group in patients with AMI > 4 weeks before treatment
Warbington 2013	An experimental study of allogeneic cryopreserved purified CD34+ cells to identify potential mi- croRNAs as biomarkers for CD34+ cell SDF-1 driven migration
Yang 2010	A RCT of BMSC in patients with AMI randomised to delivery via an infarct-related versus non-infarct related artery. This trial does not include a randomised control group
Yu 2005	A single-arm trial of BMMNC in AMI with no control group
Yu 2014	A RCT of G-CSF mobilised peripheral blood stem cells versus no cells in patients with AMI. The con- trol group did not receive the co-intervention of G-CSF

AMI, acute myocardial infarction; BMMNC, bone marrow-derived mononuclear cells; BMSC, bone marrow-derived stem cell; CABG, coronary artery bypass graft; CDC, cardiosphere-derived stem cells; E-CMM, endothelial-like culture modified mononuclear cells; G-CSF, granulocyte colony stimulating factor; MI, myocardial infarction; MSC, mesenchymal stromal cells; OMI, old myocardial infarction; PBSC, peripheral blood stem cells; RCT, randomised controlled trial; SDF-1, stromal derived factor, STEMI, ST-segment elevation myocardial infarction

	<i>Length of follow-up</i> : 6 months
	Number (N) of participants randomised to each arm: not reported
	Number (N) of participants analysed (primary outcome) in each arm: not reported
Participants	Population: AMI

Stem cell treatment for acute myocardial infarction (Review)

Lu 2012b (Continued)	Age mean (SD) each arm: 52.18 (9.98) years Sex % male in each arm: 72% male and 28% female Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported Statistically significant baseline imbalances between the groups?: none
Interventions	Intervention arm: BMSC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: not reported Dose of stem cells: not reported Timing of stem cell procedure: not reported Comparator arm: not reported
Outcomes	Primary outcomes: feasibility and safety Secondary outcomes: LVEF, LVEDV, LVESV, cardiac output, cardiac index, cardiac mass Outcome assessment points: 6 months Method(s): MRI
Notes	_

#### Park 2011

Methods	Type of study: parallel RCT
	<i>Type of publication</i> : abstract <i>Source of funding</i> : not reported
	Country of origin: not reported
	Number of centres: not reported
	Dates of trial enrolment: not reported
	<i>Length of follow-up</i> : 6 months
	Number (N) of participants randomised to each arm: 26 to control and 28 to treatment
	Number (N) of participants analysed (primary outcome) in each arm: not reported
Participants	Population: ST elevation MI (STEMI) Age mean (SD) each arm: not reported Sex % male in each arm: not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported Statistically significant baseline imbalances between the groups?: none reported
Interventions	Intervention arm: mesenchymal stem cells (MSC) Type of stem cells: MSC Summary of how stem cells were isolated and type and route of delivery: not reported, MSC were cultured for 4 weeks
	Dose of stem cells: 1 x 10 <sup>6</sup> cells Timing of stem cell procedure: not reported

Stem cell treatment for acute myocardial infarction (Review)

Park 2011 (Continued)	Comparator arm: not reported	
Outcomes	<i>Primary outcomes</i> : changes in Heart Rate Variability (HRV) <i>Secondary outcomes</i> : arrhythmias, adverse events, LVEF <i>Outcome assessment points</i> : baseline, 1 month and 6 months <i>Method(s)</i> : SPECT and transthoracic echocardiography	
Notes	_	

#### Perez-Oteyza 2006

Methods	Type of study: parallel RCT
	We are awaiting further information on number of included and followed up patients and full publi- cation details
Participants	<i>Population</i> : patients with AMI. BMSC transplantation after successful PCI <i>Age mean (SD) each arm</i> : not reported <i>Sex % male in each arm</i> : not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported Statistically significant baseline imbalances between the groups? not reported
Interventions	Intervention arm: BMSC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirate (30 to 40 mL). Cells were separated by gradient centrifugation. Cells were infused after successful PCI by intracoronary transfer
	<i>Dose of stem cells</i> : a single dose of 1.34 (0.65 to 4.0) x 10 <sup>8</sup> /mL mononuclear cells <i>Timing of stem cell procedure</i> : 1 week after PCI
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: LVEF, LVEDV, LVESV Secondary outcomes: not reported Outcome assessment points: baseline and 6 months Method(s): cMRI
Notes	_

<i>Type of publication:</i> abstract <i>Source of funding</i> : not reported	
Country of origin: Spain	
Number of centres: multicentre	
Dates of trial enrolment: not reported	
Length of follow-up: 12 months	

Stem cell treatment for acute myocardial infarction (Review)

anchez-Fernandez 2012 (Continued	<sup>a)</sup> Number (N) of participants randomised to each arm: 30 control, 30 BMMNC, 30 G-CSF, 30 BMMNC and G-CSF
	Number (N) of participants analysed (primary outcome) in each arm: not reported
Participants	<i>Population</i> : patients with AMI. BMSC transplantation after successful PCI <i>Age mean (SD) each arm</i> : not reported <i>Sex % male in each arm</i> : not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported, but BMSC treatment 3 to 5 days post- PCI Statistically significant baseline imbalances between the groups? not reported
Interventions	Intervention arm: BMSC alone or BMSC and G-CSF or G-CSF alone Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: not reported, except for in- tracoronary delivery of the cells
	<i>Dose of stem cells</i> : not reported <i>Timing of stem cell procedure</i> : 3 to 5 days after PCI, G-CSF given for 5 days <i>Comparator arm</i> : no additional therapy (control)
Outcomes	Primary outcomes: changes in LVEF and LVESV Secondary outcomes: not reported Outcome assessment points: baseline and 12 months Method(s): MRI
Notes	_

ilva 2014	
Methods	Type of study: parallel RCT
	<i>Type of publication</i> : abstract <i>Source of funding</i> : not reported
	Country of origin: Portugal
	Number of centres: 1
	Dates of trial enrolment: 01/2011 to 05/2013
	<i>Length of follow-up</i> : 12 months
	Number (N) of participants randomised to each arm: not reported
	Number (N) of participants analysed (primary outcome) in each arm: not reported
Participants	Population: patients with AMI. BMSC transplantation after successful PCI. PCI within 12 hours of AMI Age mean (SD) each arm: 50.9 (9.5) years Sex % male in each arm: 91% male
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: < 12 hours

Notes	www.clinicaltrials.gov: NCT00765453

SRCTN17457407	
Trial name or title	Bone marrow transfer to enhanced ST-elevation infarct regeneration-2 (BOOST-2)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : German Research Foundation (Deutsche Forschungsgemeinschaft)
	<i>Country of origin</i> : Bulgaria, Germany, Norway <i>Number of centres</i> : not reported (multicentre)
	Intended enrolment: 200
Participants	Population: first AMI Age, mean (SD) each arm: not reported (> 30 years) Sex, % male in each arm: not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: >2/3 of left ventricular anteroseptal, lateral or inferi- or wall Time from symptom onset to initial treatment: > 3 hours to PCI Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: high dose and low dose of non-irradiated and irradiated BMSC Type of stem cells: BMSC Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirate Dose of stem cells: low and high dose Timing of stem cell procedure: not reported
	Comparator arm: placebo medium
Outcomes	Primary outcomes: changes in LVEF from baseline to 6 months

Stem cell treatment for acute myocardial infarction (Review)

# ISRCTN17457407 (Continued) Secondary outcomes: changes in LVEF at 18 months, LVEDV, LVESV, exercise capacity, quality of life, combined endpoint mortality and heart failure<br/>Outcome assessment points: baseline, 6 and 18 months<br/>Method(s): MRI and echocardiography Starting date February 2006 Contact information Dept. of Cardiology and Angiology, Hannover Medical School, Carl-Neuberg Str.1 Hannover, Germany. Lead: Prof. Kai Wollert Notes This trial is marked as completed but no publications have as yet been identified

#### ISRCTN65630838

Trial name or title	Selected bone marrow cell transplantation following MI in patients undergoing coronary surgery
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : Bristol Royal Infirmary
	Country of origin: UK Number of centres: 1
	Intended enrolment: 60
Participants	<i>Population</i> : recent MI (> 10 days < 3 months) undergoing bypass coronary surgery <i>Age, mean (SD) each arm</i> : not reported <i>Sex, % male in each arm</i> : not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: > 10 days < 3 months Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: CD133 <sup>+</sup> bone marrow cells Type of stem cells: bone marrow-derived CD133 <sup>+</sup> cells Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirate and selection of CD133 <sup>+</sup> cells using magnetic immunoaffinity Dose of stem cells: not reported Timing of stem cell procedure: not reported
	Comparator arm: autologous plasma
Outcomes	<i>Primary outcomes</i> : quantitative assessment of myocardium at the site of injection of CD133 <sup>+</sup> cells <i>Secondary outcomes</i> : not reported <i>Outcome assessment points</i> : not reported <i>Method(s)</i> : not reported
Starting date	June 2006
Contact information	Research and Effectiveness Department, Level 1 Old Building, Bristol Royal Infirmary, Marlborough St., Bristol, BS2 8HW
Notes	This trial is marked as completed but no publications have as yet been identified

#### Mansour 2011

Trial name or title	Comparison of intracoronary injection of CD133+ bone marrow stem cells to placebo in patients af- ter acute myocardial infarction (COMPARE-AMI)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : fonds de la recherche en santé du Québec, Miltenyi Biotec, Inc., and Boston Sci- entific in Canada
	<i>Country of origin</i> : Canada <i>Number of centres</i> : 1
	Intended enrolment: not reported
Participants	Population: AMI Age, mean (SD) each arm: 52.2 (8.9) years Sex, % male in each arm: 90% male
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BMSC Type of stem cells: bone marrow-derived CD133-positive cells Summary of how stem cells were isolated and type and route of delivery: BM aspiration and separa- tion of mononuclear cells using gradient centrifugation. CD133-positive cells were immunomagnet- ically separated using the Clinimacs (Miltenyi) Dose of stem cells: not reported Timing of stem cell procedure: < 12 hours
	Comparator arm: saline and 10% autologous plasma
Outcomes	<i>Primary outcomes</i> : safety and efficacy and functional effect of the treatment <i>Secondary outcomes</i> : not reported <i>Outcome assessment points</i> : baseline, 4 months and 12 months <i>Method</i> (s): echocardiography, MRI, LV angiography
Starting date	_
Contact information	_
Notes	_

Trial name or title	Early effect of autologous bone marrow stem cell therapy on left ventricular systolic function in acute myocardial infarction patients and low left ventricular ejection fraction - a pilot study
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	<i>Country of origin</i> : Romania <i>Number of centres</i> : 1
	Intended enrolment: not reported
Participants	Population: AMI, LVEF < 40% Age, mean (SD) each arm: not reported Sex, % male in each arm: not reported

Stem cell treatment for acute myocardial infarction (Review)

Micheu 2013 (Continued)	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported Statistically significant baseline imbalances between the groups? not reported
Interventions	Intervention arm: BMSC Type of stem cells: bone marrow-derived stem cells (mononuclear cells-MNC) Summary of how stem cells were isolated and type and route of delivery: bone marrow aspiration and gradient centrifugation to isolate mononuclear cells. Cells were administered via intracoronary infusion Dose of stem cells: not reported Timing of stem cell procedure: 7 to 13 days following PCI Comparator arm: not reported
Outcomes	Primary outcomes: changes in LVEF Secondary outcomes: not reported Outcome assessment points: 1 month Method(s): not reported
Starting date	
Contact information	_
Notes	_

#### NCT00529932

Trial name or title	A trial using CD133 enriched bone marrow cells following primary angioplasty for acute myocardia infarction (SELECT-AMI)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	<i>Country of origin</i> : Belgium, France, The Netherlands, United Kingdom <i>Number of centres</i> : 4
	Intended enrolment: 19
Participants	Population: AMI Age, mean (SD) each arm: not reported (20 to 75 years) Sex, % male in each arm: not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: presence of severe hypokinesia and/or akinesia in >= 2 adjacent segments on echocardiogram at 48 to 72 hours after primary PCI Time from symptom onset to initial treatment: 2 to 24 hours after onset of chest pain Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: CD133 <sup>+</sup> cells Type of stem cells: bone marrow-derived selected CD133 <sup>+</sup> cells Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirated, CD133 <sup>+</sup> cells selected, intracoronary injection of autologous CD133 <sup>+</sup> cells Dose of stem cells: not reported Timing of stem cell procedure: not reported
	Comparator arm: buffered normal saline

Stem cell treatment for acute myocardial infarction (Review)

#### NCT00529932 (Continued)

Outcomes	<i>Primary outcomes</i> : 1) Safety - progression in coronary atherosclerosis burden proximal and distal to the stented segment of the infarct-related artery, 2) Efficacy - changes in myocardial thickening in non-viable akinetic/hypokinetic LV wall segments by cardiac magnetic resonance imaging (cMRI) <i>Secondary outcomes</i> : 1) Safety - development of ventricular arrhythmias including failed sudden cardiac death, development of congestive heart failure 2) Efficacy - LVEF, epicardial resistance and microvascular resistance, the feasibility of the CliniMACS® Reagent System to yield 5 x 106 CD133+ cells from 100 to 150 mL of autologous bone marrow <i>Outcome assessment points</i> : baseline and 6 months <i>Method(s)</i> : cMRI, echocardiography
Starting date	September 2007
Contact information	Jozef Bartunek, MD (jozef.bartunek@olvz-aalst.be); Jonathan Hill, MD (jonathan.hill@kcl.ac.uk)
Notes	This study has been terminated due to insufficient recruitment

Trial name or title	Reinfusion of enriched progenitor cells and infarct remodeling in acute coronary syndrome (REPAIR-ACS)	
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported	
	<i>Country of origin</i> : Germany <i>Number of centres</i> : 1	
	Intended enrolment: 31	
Participants	<i>Population</i> : acute non-ST segment elevation myocardial infarction, successful PCI with stent <i>Age, mean (SD) each arm</i> : not reported (18- to 80 years) <i>Sex, % male in each arm</i> : not reported	
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: < 48 hours Statistically significant baseline imbalances between the groups?: not reported	
Interventions	Intervention arm: BMSC Type of stem cells: bone marrow stem cells Summary of how stem cells were isolated and type and route of delivery: bone marrow aspirated, preparation of media, delivery via intracoronary injection Dose of stem cells: not reported Timing of stem cell procedure: not reported	
	Comparator arm: placebo medium	
Outcomes	<i>Primary outcomes</i> : improvement of coronary flow reserve in the infarct vessel <i>Secondary outcomes</i> : improvement of relative coronary flow reserve, regional and global LVEF, MACE (death, MI, rehospitalisation for heart failure, revascularisation) <i>Outcome assessment points</i> : baseline, 4 months and 1 year <i>Method(s)</i> : intracoronary doppler wire	
Starting date	September 2008	
Contact information	Andreas M Zeiher, MD (zeiher@em.uni-frankfurt.de); Birgit Assmus, MD (b.assmus@em.uni-frank furt.de)	

Stem cell treatment for acute myocardial infarction (Review)

#### NCT00711542 (Continued)

Notes

This study has been terminated due to slow recruitment

#### NCT00936819

Trial name or title	The enhanced angiogenic cell therapy - acute myocardial infarction trial (ENACT-AMI)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	Country of origin: Canada Number of centres: 5
	Intended enrolment: 100
Participants	Population: AMI Age, mean (SD) each arm: not reported (18 to 80 years) Sex, % male in each arm: not reported
	Number of diseased vessels: not reported
	<i>Number of stunned hyperkinetic, etc segments</i> : not reported <i>Time from symptom onset to initial treatment</i> : not reported
	Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: endothelial progenitor cells (EPC) or eNOS transfected EPC Type of stem cells: endothelial progenitor cells (EPC) Summary of how stem cells were isolated and type and route of delivery: not reported Dose of stem cells: 20 x 10 <sup>6</sup> cells in each treatment arm
	<i>Timing of stem cell procedure</i> : after 5 to 7 days
	Comparator arm: plasmalyte and 25% autologous plasma
Outcomes	Primary outcome: change in LVEF
	Secondary outcomes: changes in wall motion, clinical worsening, QoL and safety
	<i>Outcome assessment points</i> : baseline and 6 months <i>Method(s)</i> : MRI
Starting date	July 2013
Contact information	Contact: Dr. Duncan J. Stewart, MD FRCP C, Ottawa Hospital Research Institute

# NCT01187654 (Continued)

Contact information Principal Investigator: Masoud Ghassemi, MD; Royan Institute, Tehran, Islamic Republic of Iran Notes This trial is marked as completed but no publications have as yet been identified

Trial name or title	Endocardial mesenchymal stem cells implantation in patients after acute myocardial infarction (ESTIMATION Study)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	<i>Country of origin</i> : Russia <i>Number of centres</i> : not reported
	Intended enrolment: 50
Participants	<i>Population</i> : AMI with successful PCI <i>Age, mean (SD) each arm</i> : not reported (30 to 75 years) <i>Sex, % male in each arm</i> : not reported
	Number of diseased vessels: 1 Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BM-MSC Type of stem cells: bone marrow-derived mesenchymal stem cells Summary of how stem cells were isolated and type and route of delivery: not reported, except for de- livery using NOGA mapping Dose of stem cells: not reported Timing of stem cell procedure: 7 to 10 days after PCI
	Comparator arm: placebo
Outcomes	<i>Primary outcomes</i> : reduction of LVESV by 15% <i>Secondary outcomes</i> : death, Thrombosis, hospitalisation for HF, 6 min-walk, BNP levels <i>Outcome assessment points</i> : baseline, 12 months <i>Method(s)</i> : MRI
Starting date	July 2011
Contact information	Principal Investigator: Professor Evgeny Pokushalov, MD; State Research Institute of Circulation Pathology, Novosibirsk, Russian Federation, 630055
Notes	Estimated completion date: November 2012

#### NCT01495364

Trial name or title	NBS10 (also known as AMR-001) versus placebo post ST segment elevation myocardial infarction (PreSERVE-AMI)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : NeoStem, Inc.

Stem cell treatment for acute myocardial infarction (Review)

NCT01495364 (Continued)	<i>Country of origin</i> : USA <i>Number of centres</i> : not reported <i>Intended enrolment</i> : 160
Participants	Population: AMI Age, mean (SD) each arm: not reported (> 18 years) Sex, % male in each arm: not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: not reported Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: CD34-positive cells Type of stem cells: bone marrow-derived CD34-positive cells Summary of how stem cells were isolated and type and route of delivery: not reported, intracoronary delivery Dose of stem cells: not reported Timing of stem cell procedure: not reported Comparator arm: placebo
Outcomes	Primary outcomes: AE, SAE, MACE and myocardial perfusion Secondary outcomes: not reported Outcome assessment points: baseline, 6 months and 36 months Method(s): SPECT
Starting date	December 2011
Contact information	Principal Investigator: Arshed Quyyumi, MD, Emory University
Notes	Estimated completion date: June 2014

#### NCT01536106

Trial name or title	Rapid delivery of autologous bone marrow derived stem cells in acute myocardial infarction pa- tients (AMIRST)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : TotipotentRX Cell Therapy Pvt. Ltd.
	<i>Country of origin</i> : India <i>Number of centres</i> : not reported
	Intended enrolment: 30
Participants	Population: AMI, LVEF < 40%
	<i>Age, mean (SD) each arm</i> : not reported (18 to 75 years)
	Sex, % male in each arm: not reported
	Number of diseased vessels: not reported
	Number of stunned hyperkinetic, etc segments: not reported
	Time from symptom onset to initial treatment: PCI within 24 hours of MI
	Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BMMNC
	<i>Type of stem cells</i> : bone marrow-derived mononuclear cells

Stem cell treatment for acute myocardial infarction (Review)

NCT01536106 (Continued)	Summary of how stem cells were isolated and type and route of delivery: not reported, intracoronary delivery Dose of stem cells: not reported Timing of stem cell procedure: 3 to 10 days after AMI Comparator arm: placebo
Outcomes	<i>Primary outcomes</i> : AE <i>Secondary outcomes</i> : changes in LVEF, LVEDV, LVESV, infarct size, myocardial perfusion, MACE and QoL <i>Outcome assessment points</i> : baseline and 12 months Method (s): cardiac MRI
Starting date	December 2013
Contact information	Principal Investigators: Sreenivas A Kumar, MD, DM, FACC; CARE Hospitals, Hyderabad, India; Up- endra Kaul, MD,DM, FACC; Fortis Flt. Lt. Rajan Dhall Hospital and Ashok Seth, FRCP, FACC; Fortis Es- corts Heart Institute and Research Centre, India
Notes	Estimated completion date: January 2015

#### NCT01569178

Trial name or title	The effect of intracoronary reinfusion of bone marrow-derived mononuclear cells (BM-MNC) on all cause mortality in acute myocardial infarction (BAMI)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	<i>Country of origin</i> : Belgium, Czech Republic, Denmark, Finland, France, Germany, Italy, Poland, Spain, UK <i>Number of centres</i> : 24
	Intended enrolment: 3000
Participants	Population: AMI, LVEF ≤ 45% Age, mean (SD) each arm: not reported (> 18 years) Sex, % male in each arm: not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: thrombolytic therapy within 24 hours of MI and PCI within 24 hours of therapy Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived mononuclear cells Summary of how stem cells were isolated and type and route of delivery: intracoronary delivery of BMMNC isolated from bone marrow aspirates and gradient centrifugation Dose of stem cells: not reported Timing of stem cell procedure: not reported
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: time to all-cause death
	<i>Secondary outcomes</i> : time to cardiovascular death, time to cardiovascular hospitalisation for MI, revascularisation, HF, etc., SAE and bleeding

Stem cell treatment for acute myocardial infarction (Review)

NCT01569178 (Continued)	<i>Outcome assessment points</i> : baseline and 36 months <i>Method(s)</i> : cardiac MRI
Starting date	September 2013
Contact information	Principal Investigator: Professor Anthony Mathur, MB BChir, FRCP, PhD; Queen Mary University of London, UK
Notes	Estimated completion date: May 2017

#### NCT01625949

Trial name or title	Stem cell therapy in patients with myocardial infarction and persistent total occlusion of infarct re- lated artery (COAT)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	<i>Country of origin</i> : India <i>Number of centres</i> : 1
	Intended enrolment: 40
Participants	Population: AMI Age, mean (SD) each arm: not reported (18 to 80 years) Sex, % male in each arm: not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: time to PCI < 24 hours. Time to cell treatment > 24 hours Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived mononuclear cells Summary of how stem cells were isolated and type and route of delivery: intracoronary delivery of BMMNC isolated from bone marrow aspirates and gradient centrifugation Dose of stem cells: not reported Timing of stem cell procedure: not reported
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: changes in LVEF
	<i>Secondary outcomes</i> : changes in functional capacity (NYHA class), 6 minute walking distance, QoL, recurrent MI or death <i>Outcome assessment points</i> : baseline and 3 months <i>Method</i> (s): PET
Starting date	March 2011
Contact information	Principal Investigator: Sandeep Seth, DM; All India Institute of Medical Sciences, New Delhi, India
Notes	Estimated completion date: June 2014

#### NCT01652209

Trial name or title	A randomised, open labeled, multicenter trial for safety and efficacy of intracoronary adult human mesenchymal stem cells acute myocardial infarction (RELIEF)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : Pharmicell Co., Ltd
	<i>Country of origin</i> : Korea <i>Number of centres</i> : not reported
	Intended enrolment: 135
Participants	Population: AMI, LVEF < 45% Age, mean (SD) each arm: not reported (20 to 70 years) Sex, % male in each arm: not reported
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: within 30 days of MI Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BM-MSC Type of stem cells: bone marrow-derived mesenchymal stem cells Summary of how stem cells were isolated and type and route of delivery: intracoronary delivery of MSC, not reported how they are cultured Dose of stem cells: not reported Timing of stem cell procedure: after 30 days (single dose) or after 30 and 60 days (double dose)
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: changes in LVEF
	Secondary outcomes: not reported Outcome assessment points: baseline and 13 months Method(s): MRI
Starting date	October 2013
Contact information	Principal Investigator: Yang Soo Jang, Ph.D. M.D.; Severance Hospital, Yonsei University College of Medicine; Korea
Notes	Estimated completion date: December 2018

Trial name or title	Impact of intracoronary injection of autologous BMMC for LV contractility and remodeling in pa- tients with STEMI (RACE-STEMI)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	<i>Country of origin</i> : Poland <i>Number of centres</i> : not reported
	Intended enrolment: 200
Participants	Population: AMI, LVEF ≤ 45% Age, mean (SD) each arm: not reported (> 18 years) Sex, % male in each arm: not reported

Stem cell treatment for acute myocardial infarction (Review)

NCT02323620 (Continued)	
	Number of diseased vessels: not reported
	Number of stunned hyperkinetic, etc segments: not reported
	Time from symptom onset to initial treatment: not reported
	Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BMMNC
	Type of stem cells: bone marrow-derived mononuclear cells
	Summary of how stem cells were isolated and type and route of delivery: intracoronary delivery of
	BMMNC isolated from BM aspirates and gradient centrifugation
	Dose of stem cells: not reported
	Timing of stem cell procedure: not reported
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: changes in LVEF at 12 months
	Secondary outcomes: LVEDV, LVESV, time to cardiac death, hospitalisation for HF, SAE
	Outcome assessment points: baseline, 12 months and 36 months
	Method(s): CT
Starting data	March 2015
Starting date	March 2015
Contact information	Principal Investigator: Pawel E Buszman, MD, PhD; American Heart of Poland, Poland
Notes	Estimated completion date: July 2018

#### Pena-Duque 2011

Trial name or title	Intracoronary autologous stem cell transplantation in ST-elevation myocardial infarction (TRACIA STUDY)
Methods	<i>Type of study</i> : parallel RCT <i>Source of funding</i> : not reported
	<i>Country of origin</i> : Mexico <i>Number of centres</i> : not reported
	Intended enrolment: not reported
Participants	Population: AMI Age, mean (SD) each arm: 53.25 (5.7) years Sex, % male in each arm: 87.5%
	Number of diseased vessels: not reported Number of stunned hyperkinetic, etc segments: not reported Time from symptom onset to initial treatment: within 24 hours Statistically significant baseline imbalances between the groups?: not reported
Interventions	Intervention arm: BMMNC Type of stem cells: bone marrow-derived mononuclear cells Summary of how stem cells were isolated and type and route of delivery: bone marrow aspiration and separation of mononuclear cells using a Sepax machine and a gradient centrifugation Dose of stem cells: adjusted for CD34-positive cells 1 to 2 x 10 <sup>6</sup> CD34 cells Timing of stem cell procedure: day 5 to 6 after AMI
	Comparator arm: no additional therapy (control)
Outcomes	Primary outcomes: safety changes in LVEF from baseline to 6 months

Stem cell treatment for acute myocardial infarction (Review)

Pena-Duque 2011 (Continued)	<i>Secondary outcomes</i> : death, re-infection, restenosis, thrombosis, adverse events, LVEF <i>Outcome assessment points</i> : baseline, 6 months <i>Method</i> (s): MRI and SPECT
Starting date	_
Contact information	Marco Antonio Pena Duque, Juan Badiano No. 1, Col Cession XVI, Llalpan, 14080 Mexico. Email: penmar@cardiologia.org.mx
Notes	_

AE, adverse effect; AMI, acute myocardial infarction; BFU-E, burst-forming unit - erythrocyte, BM, bone marrow; BMMNC, bone marrowderived mononuclear cells; BMSC, bone marrow-derived stem cells; BM-CPC, bone marrow-derived circulating progenitor cells; BOOST, Benefits of Oxygen Saturation Targeting; CFU-GEMM, colony-forming unit - granulocyte erythrocyte monocyte megakaryocyte; CFU-GM, colony-forming unit - granulocyte monocyte, CK-MB, creatine-kinase muscle and brain; cMRI, cardiac magnetic resonance imaging; CO, FACS, fluorescence-activated cell sorting; G-CSF, granulocyte colony stimulating factor; IVUS, intravascular ultrasound; LAD, left anterior descending; LV, left ventricle or ventricular; LVEDV, left ventricular end-diastolic volume; LVEF, left ventricular ejection fraction; LVESV, left ventricular end-systolic volume; MACE, major adverse cardiac events; MI, myocardial infarction; MIBI, methoxyisobutylisonitrile; MNC, mononuclear cells; MRI, magnetic resonance imaging; MUGA, Multi Gated Acquisition Scan; MVO<sub>2</sub>, myocardial volume oxygen consumption; PCI, percutaneous coronary intervention; PET, positron emission tomography; QoL, quality of life; QLV, quantitative left ventriculography; SAE, serious adverse effect; SC, stem cells; SD, standard deviation; SPECT, single photon emission computed tomography; STEMI, ST-segment elevation myocardial infarction; VEGF, vascular endothelial growth factor; WMSI, wall motion score index

## DATA AND ANALYSES

#### Comparison 1. Cells compared to no cells

Outcome or subgroup title	No. of studies	No. of partici- pants	Statistical method	Effect size	
		panto			
1 All-cause mortality	23		Risk Ratio (M-H, Random, 95% CI)	Subtotals only	
1.1 Short-term follow-up (< 12 months)	17	1365	Risk Ratio (M-H, Random, 95% CI)	0.80 [0.43, 1.49]	
1.2 Long-term follow-up (≥ 12 months)	14	996	Risk Ratio (M-H, Random, 95% CI)	0.93 [0.58, 1.50]	
2 Cardiovascular mortality	10		Risk Ratio (M-H, Random, 95% CI)	Subtotals only	
2.1 Short-term follow-up (< 12 months)	7	290	Risk Ratio (M-H, Random, 95% CI)	0.72 [0.28, 1.82]	
2.2 Long-term follow-up (≥ 12 months)	9	527	Risk Ratio (M-H, Random, 95% CI)	1.04 [0.54, 1.99]	
3 Composite measure of death, reinfarction, re-hospitalisation for heart failure	6		Risk Ratio (M-H, Random, 95% CI)	Subtotals only	
3.1 Short-term follow-up (< 12 months)	3	379	Risk Ratio (M-H, Random, 95% CI)	0.36 [0.12, 1.14]	
3.2 Long-term follow-up (≥ 12 months)	6	497	Risk Ratio (M-H, Random, 95% CI)	0.63 [0.36, 1.10]

Cochrane Database of Systematic Reviews

Cochrane Library

FR - full reporting, outcome included in analysis

PR - partial reporting, insufficient information on outcome reported for inclusion in analysis

\* no incidence of outcome observed

NR - outcome not reported

HF - heart failure; NYHA - New York Heart Association; LVEF - left ventricular ejection fraction

<sup>(a)</sup>Composite measure of mortality, reinfarction or rehospitalisation for heart failure.

<sup>(b)</sup>LVEF measured by any method.

(c) Total number of participants included in meta-analysis of outcome (% of total number of participants from all included studies).

<sup>(d)</sup>Total number analysed given for LVEF measured by magnetic resonance imaging.

# Table 5. Periprocedural adverse events

Study ID	Periprocedural adverse events
Angeli 2012	Not reported
Cao 2009	1 x transient acute heart failure 7 days after cell transplantation
Chen 2004	Not reported
Colombo 2011	No adverse events were reported until the end of hospitalisation
Gao 2013	1 x death 3 days after cell transplantation due to suspected acute in-stent thrombosis; 1 x serious complication of acute coronary occlusion during cell injection with subsequent recurrent MI
Ge 2006	No bleeding complications at BM puncture site and no angina aggravation, malignant diseases or substantial arrhythmias after PCI and BM transfer during hospitalisation in either treatment group
Grajek 2010	Not reported
Hirsch 2011	No complications of cell harvesting. A CK or CK-MB elevation between 1 and 2 times the ULN was detected in 4 patients and between 2 and 3 times the ULN in one patient. 1 x occluded infarct-related artery (patient did not receive cell therapy as randomised). During cell catheterisation: 1 x coronary spasm, 1 x transient brachycardia and 1 x thrombus in the infarct related artery
Huang 2006	Not reported
Huang 2007	Not reported
Huikuri 2008	3 x mild self terminating vasovagal reactions during BM aspiration; no other procedural complica- tions relating to aspiration. Subacute stent thrombosis occurred in 4 patients (1 x cell therapy and 3 x placebo); 1 x cell therapy patient had 'no reflow' phenomenon after stenting of the infarcted artery
Janssens 2006	11 x treatment-related tachycardia (supraventricular arrhythmia: 5 in the cell therapy group and 6 in the control group); 3 patients in the control group experienced non-sustained ventricular tachy-cardia
Jazi 2012	Not reported
Jin 2008	Not reported
Karpov 2005	No complications of BM aspiration or cell infusion
Lee 2014	No serious inflammatory reactions or bleeding complications from BM aspiration. No (or mild) angina during balloon inflation. No serious procedural complications related to intracoronary ad- ministration of MSCs including ventricular arrhythmia, thrombus formation or dissection. Peripro- cedural MI occurred in 2 patients
Lunde 2006	2 x stent thrombosis in the acute phase in the cell therapy group (no cells administered as ran- domised); 1 x sustained ventricular tachycardia before cell administration; 1 x ventricular fibrilla- tion at day 6, 24 hours after injection.1 x pulseless ventricular tachycardia in control patient - con- verted to sinus rhythm by means of a precordial thump on day 2
Meluzin 2008	2 patients had fever and 1 patient had brachycardia, all within 20 hours prior to cells (these pa- tients did not receive cell therapy as randomised). 3 x cell therapy-related complications: 1 x inti- mal dissection during repeat balloon inflations at time of cell implantation, 1 x short-lasting fever on day of scheduled transplantation, 1 x small thrombus in infarct-related artery diagnosed imme-

Stem cell treatment for acute myocardial infarction (Review)

# Table 5. Periprocedural adverse events (Continued)

	diately after cell transplantation. 2 x control patients had repeat MI 2 days after the hospital dis- charge due to in-stent thrombosis
Nogueira 2009	Ck-MB elevation (3 x normal value) in 3 patients in the arterial group and 1 patient in venous group. 1 x tortuous anterior interventricular vein (patient did not receive cell therapy as randomised). No new pericardial effusions
Penicka 2007	2 x serious complications (1 x stent thrombosis with reinfarction immediately after BM harvest, pa- tient died 2 weeks later due to sepsis and acute respiratory distress syndrome; 1 x ventricular sep- tal rupture before cell injection, patient died 3 months later from severe heart failure).
Piepoli 2010	All procedures well tolerated. No inflammatory reaction or abscess detected at the site of puncture after BM harvest. The invasive coronary catheterisation was associated with some mild angina dur- ing balloon inflations for cell infusions. No procedural complications during cardiac catheterisation related to cell injections (no ventricular arrhythmia, new thrombus formation or embolism after cell infusion or dissections due to balloon inflations)
Plewka 2009	Not reported
Quyyumi 2011	1 high-dose treatment group patient died soon after cell infusion from ventricular fibrillation attrib- uted to recurrent MI from stent thrombosis preceding cell infusion. 1 x high-dose treatment group patient with acute stent thrombosis before cell infusion (patient withdrawn from study). Cell thera- py group: 1 x arrhythmia, 1 x chest pain, 3 x musculoskeletal pain, 2 x upper respiratory tract infec- tion, 2 x rash, 3 x dyspnoea, 1 x fever. Control group: 1 x arrhythmia, 3 x musculoskeletal pain, 1 x upper respiratory tract infection, 1 x dyspnoea
Roncalli 2010	Cell therapy group: 1 x transient ischaemic attack and 1 x thrombopenia induced by GP2b3a in- hibitor (both excluded before BM aspiration). Control group: 1 x steroids given for angioneurotic oedema; 1 x post-MI ventricular septal defect (both withdrawn before day 7)
Ruan 2005	Not reported
Schachinger 2006	No bleeding complications or haematoma formation at puncture site of BM aspiration. 1 x patient was excluded owing to fever and an increase in the level of C-reactive protein. 1 x patient in place- bo group had angiographic evidence of a thrombus in a non-infarct-related artery (placebo medi- um not infused). 2 x deaths, cause not reported (1 x cell therapy group and 1 x placebo) and 2 x re- infarction (cell therapy group) prior to discharge
Suarez de Lezo 2007	Not reported
Sürder 2013	1 death in cell therapy group prior to transplantation, cause of death not reported
Tendera 2009	1 patient developed arteriovenous fistula of the femoral artery after the procedure and required surgical treatment. No complications arising from BM cell transfer
Traverse 2010	BM aspiration carried out without complications. No patient experienced a rise in troponin or pro- cedure-related complication following infusion
Traverse 2011	No complications associated with BM aspiration. 2 x patients underwent additional stenting at time of cell infusion (1 x distal stent edge dissection related to primary PCI procedure; 1 x possible dissection related to stop-flow procedure). 1 x postpartum spontaneous coronary dissection with diffuse thrombus throughout stented region of left anterior descending artery; 1 x presence of severe left main coronary stenosis identified before transfusion (this patient did not receive cell therapy as randomised). No patients experienced postprocedural increase in cardiac enzymes
Traverse 2012	No complications associated with BM harvesting or intracoronary infusion. 1 x death in the BM cell therapy group due to subarachnoid haemorrhage prior to cell delivery

Cochrane Library

Trusted evidence. Informed decisions. Better health.

195

| n/r - not reported

LD - low dose, MD - moderate dose, HD - high dose, AG - arterial group, VG - venous group, E - early cells, L - late cells, S - selected cells, U - unselected cells, SD - single dose, DD - double dose

(a) Schachinger 2006: MRI was performed at five-year follow-up but summary results only were reported; 24-month data are used in meta-analysis.

(b)Zhukova 2009: 24-month data were used in the analysis as only one control was available at 36 months.

(c) Roncalli 2010: echocardiography was performed at 12-month follow-up but summary results only were reported; three-month data are used in meta-analysis.

(d) Wang 2014: the reported baseline LVEF value in the control group is assumed to be an error since the difference between values at baseline and endpoint (49.1%) is not significant. We have been unable to clarify the correct value with the study authors.

### WHAT'S NEW

Date	Event	Description
30 June 2015	New search has been performed	The searches from 2011 were re-run in March 2015.
		This is a major update, which includes 41 independent trials. Two trials that were included in the previous version of the re- view are now excluded since the co-intervention of G-CSF was only administered to the intervention arm (Kang 2006; Li 2006). One trial that was previously included is now defined as awaiting classification as this trial did not publish any data that could be incorporated into the analyses (Fernandez-Pereira 2006).
		In this update we have revised the primary and secondary out- comes, which now focus on clinical outcomes as well as the sur- rogate endpoint of left ventricular ejection fraction. Multiple in- tervention arm trials are now pooled throughout the review, avoiding double counting of controls. In light of the potential sources of heterogeneity, meta-analyses using random-effects models are now performed throughout.
30 June 2015	New citation required and conclusions have changed	This update includes 11 new trials and the conclusions of the re- view have changed. We no longer find evidence of an improve- ment in left ventricular ejection fraction associated with stem cell therapy. Meta-analyses of the increased number of trials in this update have failed to find any evidence of differences in clinical outcomes between treatment groups. We conclude that

Stem cell treatment for acute myocardial infarction (Review)

Date

Event

Description

there is insufficient evidence of a beneficial effect of stem cell therapy for acute myocardial infarction patients.

# HISTORY

Protocol first published: Issue 2, 2007 Review first published: Issue 4, 2008

Date	Event	Description
16 December 2011	New citation required and conclusions have changed	This is a major update including 33 randomised trials (formerly 13) with changes to the conclusions. Whilst in the previous ver- sion of this review there was little evidence to assess the effect of this treatment, the results of this update of the review indicate that the treatment moderately improves heart function and con- tractility and that this effect is sustained in the long term. How- ever, in order to observe significant changes in mortality and morbidity larger numbers of participants would need to be en- rolled in such trials and more robust surrogate outcome mea- sures to be agreed and standardised.
16 December 2011	New search has been performed	Addition of 20 new trials identified from a search from July 2007 to January 2011. Additional secondary references with long-term follow-up from previously included trials were also identified in this search.
		Change from Meluzin 2006 (LD and HD) to <u>Meluzin 2008</u> (LD and HD). <u>Meluzin 2008</u> , with long-term follow-up data, has become the main study. Meluzin 2006 is now considered a substudy.
14 September 2008	Amended	Amendment to the order of authors in the byline.
2 April 2008	Amended	Converted to new review format.

## **CONTRIBUTIONS OF AUTHORS**

Sheila Fisher: methodological expert, eligibility screening, data extraction, quality assessment, data analysis and preparation of the final report.

Huajun Zhang: eligibility screening, data extraction and comment on the final report.

Carolyn Doree: design and implementation of search strategies, initial eligibility screening, data verification and comment on the final report.

Anthony Mathur: clinical content expert, preparation of the final report.

Enca Martin-Rendon: scientific content expert, eligibility screening, data extraction, quality assessment and preparation of the final report. Corresponding author who takes global responsibility for this review.

# DIFFERENCES BETWEEN PROTOCOL AND REVIEW

The original outcomes of this review have been revised in this update, focusing on clinical outcomes. However, the surrogate endpoint of LVEF is a standard, widely reported marker for cardiac function and has been retained as a reference point with other trials and systematic reviews in AMI. Surrogate outcomes other than LVEF reported in previous versions of this review, namely engraftment and survival of the infused stem cells, left ventricular end-systolic volume, left ventricular end-diastolic volume, wall motion score, stroke volume index and infarct size are no longer included. We now define revised primary outcomes as (i) all-cause mortality, (ii) cardiovascular mortality, (iii) composite measures of major adverse cardiac events (MACE), and (iv) periprocedural adverse events. Secondary outcomes include morbidity, LVEF and quality of life and performance measures.

In the protocol and previous versions of the review we implemented fixed-effect models in the first instance. It is now clear that there are many potential sources of heterogeneity across trials, and in this version of the review we have performed meta-analyses using random-effects models throughout.

In the writing of this version of the review we identified a systematic error in the previous versions of the review in the calculation of standard deviations for mean change from baseline LVEF values. This issue has now been corrected. In some studies it was not possible to accurately calculate the value of the standard deviation. These studies, previously analysed as mean change from baseline values, are now reported as mean value at endpoint; results from combined analyses of mean change from baseline and endpoint values are reported.
