#### **ABSTRACT**

## **Background**

Beclomethasone dipropionate (BDP) and budesonide (BUD) are used widely in the treatment of chronic asthma. The two drugs have different in vitro pharmacokinetic characteristics. It is unclear whether this translates into clinically significant differences in efficacy or safety when treating children and adults with chronic asthma.

## **Objectives**

To assess clinical outcomes in studies which have compared inhaled BDP and BUD in the treatment of chronic asthma.

#### **Search methods**

We searched the Cochrane Airways Group Trial Register (1999) and reference lists of articles. We contacted trialists and pharmaceutical companies for additional studies and searched abstracts of major respiratory society meetings (1997-1999).

#### **Selection criteria**

Prospective, randomised trials comparing BDP to BUD in the treatment of chronic asthma. Two reviewers independently assessed articles for inclusion and methodological quality.

## **Data collection and analysis**

One reviewer extracted data; authors were contacted to clarify missing information. Quantitative analyses where undertaken using Review Manager 4.0.3 with MetaView 3.1.

## Main results

24 studies met the criteria for inclusion (1174 participants). Methodological quality was variable. A meta-analysis of crossover studies did not demonstrate a significant difference between BDP and BUD for FEV1, morning PEF, evening PEF, asthma symptoms or rescue beta2 agonist use, over a dose range of 400 to 1000 mcg/d. The majority of crossover trials had significant design flaws related to a lack of washout and/or failure to exclude carryover effects so the results must be viewed with caution. A single crossover study with adequate washout showed that BUD 400 mcg/d delivered via Turbohaler dry powder inhaler (DPI) may be more effective than BDP 400 mcg/d delivered via Rotahaler DPI in reducing histamine bronchial hyper-responsiveness: Weighted Mean Difference (WMD) 0.43 log10 PC20 FEV1 (95% Confidence Intervals (CI) 0.05, 0.81 log10 PC20 FEV1). A meta-analysis of two parallel group, dose down-titration studies (231 patients) showed that less BUD delivered via a Turbohaler DPI was required to maintain control in adults asthmatics compared to BDP delivered via metered dose inhaler with or without a spacer: WMD 444 mcg/d (95% CI 332, 556 mcg/d).

#### **Authors' conclusions**

There is limited high quality randomised controlled trial data comparing the relative efficacy of BDP and BUD. Current guidelines (BTS 1997; GINA 1995; NHLBI 1997) assume BDP and BUD to have equal efficacy, such that for each defined level of asthma severity, the recommended doses BDP and BUD are the same. Although there is some data to suggest that BUD via Turbohaler is more effective than BDP via either Rotahaler or MDI (with and without spacer), these comparisons are confounded by use of different delivery devices, and are not sufficient to warrant a change in guideline recommendations.

## PLAIN LANGUAGE SUMMARY

#### The effects of beclomethasone or budesonide for chronic asthma

Beclomethasone and budesonide are commonly used to treat people with asthma in the long-term. Despite the large amount of research which has been conducted with these two steroids, very little can be concluded as to how effective they are, because the quality of the research to date has not been strong enough. The available research does not therefore provide a clear answer as to whether beclomethasone or budesonide are better for treating asthma.

#### BACKGROUND

Beclomethasone dipropionate (BDP) was the first inhaled corticosteroid (ICS) marketed for use in the treatment of chronic asthma in 1972. Budesonide had been available since the early 1980's. Extensive clinical experience has been gained with these compounds in the treatment of chronic asthma, both are regarded as having a highly favourable therapeutic index when compared to oral corticosteroids, i.e. offering large advantages in terms of their efficacy at the cost of few side-effects.

In vitro studies assessing pharmacodynamic properties have shown differences between BDP and BUD. Receptor affinity is a measure of the strength with which an active molecule binds to the glucocorticoid receptor. This is 1.5 fold higher for 17beclomethasone monopropionate (17-BMP), the bronchially active metabolite of BDP, compared to BUD (Boobis 1998). However when assessing drugs in terms of their relative in vitro potency, i.e. the concentration of drug required producing a standard effect, BUD appears more potent than BDP. This has been shown in early experimental studies for the MacKenzie skin-blanching test (Johansson 1982), and more recently in terms of several in vitro assays of anti-inflammatory action including eosinophil survival, basophil histamine release and expression of vascular cell adhesion molecule-1 (Stellato 1999). It is noteworthy that in these in vitro assays, the maximum effect of BDP and BUD (i.e. their intrinsic activity) was similar, and at very high concentrations (on the 'plateau' of the dose response curve) the quantitative effects of the two drugs were closely matched.

Do differences in the in vitro pharmacodynamic actions of BDP and BUD translate into differences in clinical efficacy? This may depend on dose. At low inhaled dose, more likely to be on the 'steep' portion of the dose response curve for each drug, differences in potency might lead to differences in clinical efficacy. Conversely, at higher inhaled dose (approaching or on the 'plateau' of the dose response curve for each drug) differences in clinical efficacy may not be apparent. A retrospective analysis of prescription records for BDP and BUD in primary care in New Zealand has recently been published (Pethica 1998). The investigators concluded that BDP was more 'potent' than BUD because the mean daily-prescribed dose of BDP over a one-year period was 635 mcg/d compared to a mean daily BUD dose 979 mcg/d. This study has a number of limitations however including the fact that drug exposure could not validated and other known and unknown biases may have been operating in this non-randomised, retrospective cross-sectional study.

The purpose of this review is to assess the relative clinical efficacy and safety of BDP and BUD delivered at equal nominal dose in the treatment of chronic asthma by systematically reviewing the prospective randomised trials that have compared these inhaled corticosteroids.

## **OBJECTIVES**

To assess clinical outcomes in studies which have compared inhaled beclomethasone (BDP) and inhaled budesonide (BUD) in the treatment of chronic asthma.

#### **METHODS**

## Criteria for considering studies for this review

#### Types of studies

We considered all randomised studies. Double, single and nonblinded studies were considered. Studies could be of either parallel group or crossover design.

## **Types of participants**

Studies of both children and adults were included, but patients under two years of age were excluded. To be eligible, participants had to have a diagnosis of chronic asthma. Studies conducted in both primary and secondary care settings were considered.

## Types of interventions

BDP versus BUD delivered by oral inhalation. Each drug had to be delivered at the same nominal daily dose. Nominal dose was calculated as the valve dose multiplied by the number of actuations per day. Each drug could be delivered by different device including pressurised metered dose aerosol inhaler (MDI), MDI+spacer or dry powder device (DPI). Studies using nebuliser devices were excluded.

## Types of outcome measures

All outcomes were considered. Those identified as important a priori were as follows:

#### Efficacy related

- 1. Clinic measured FEV1 and PEF, diary card morning and evening PEF, diurnal variability in PEF
- 2. Symptoms
- 3. Rescue beta2 agonist use
- 4. Histamine and methacholine bronchial hyper-responsiveness (BHR)
- 5. Asthma exacerbations: hospital admission, emergency room attendance, unscheduled primary care visits, days off school or work
- 6. Health-related quality of life (HRQOL)

## Safety related

- 1. Hypothalamo-pituitary-adrenal (HPA) axis function reflected in serum and urinary cortisol measures and clinical adrenal insufficiency
- 2. Oropharyngeal side effects (hoarseness, sore throat, oral Candidiasis)

## Search methods for identification of studies

#### **Electronic searches**

Stage 1: a search was carried out of the Cochrane Airways Group Trials Register (1999). The following search terms were applied:

steroid\* OR glucocorticoid\* OR corticosteroid\* OR beclomethasone OR budesonide OR fluticasone OR triamcinolone OR flunisolide OR Becotide OR Becloforte OR Pulmicort OR Flixotide

Abstracts from this search were imported into a bibliographic database termed the Inhaled Steroid Register. This was hand-searched by two reviewers (NPA and JB). Duplicate publications were removed.

Stage 2: two further registers were created by undertaking searches of the Inhaled Steroid Register using the following terms:

beclomethasone OR Becotide OR Becloforte: the Beclomethasone Register

budesonide OR Pulmicort: the Budesonide Register

Each register was hand-searched for RCTs meeting the inclusion criteria. Citations were excluded based on abstract if it was clear that the study was a) not concerned with the treatment of asthma in humans b) not an RCT c) did not include a treatment arm with inhaled corticosteroid (ICS). Where uncertainty existed, the publication was retrieved in full text form.

#### **Searching other resources**

Reference lists of all included trails and relevant narrative reviews were searched for additional RCTs. Authors of identified trials, Glaxo Wellcome (UK) and Astra Zeneca (Sweden) were contacted and were asked about any further published or unpublished trials that may have been conducted. There were no language restrictions. The British Journal of Clinical Research and the European Journal of Clinical Research, which are not electronically indexed on MEDLINE or EMBASE, were hand searched for relevant studies. The proceedings of the British Thoracic Society (1997/1998), European Respiratory Society (1997/1998) and the American Thoracic Society (1997-1999) were searched for relevant trials.

## **Data collection and analysis**

#### **Selection of studies**

The decision to exclude studies prior to full paper retrieval was made by one reviewer (NPA). Papers retrieved in full text form were assessed independently by two reviewers (NPA and JB); disagreement as to which papers to include was resolved by consensus.

### **Data extraction and management**

One reviewer (NPA) extracted data for each outcome from the published results of included trials. In the case of continuous outcomes such as FEV1 measures:

- 1. Where outcomes were evaluated at a number of time points only data from the last evaluable time point was used.
- 2. Data were extracted from graphical plots when presented in this form; attempt was made to verify such data by contacting authors. 3. If an intention-to-treat analysis was not used by the investigators, and it was not explicit in the presentation of results how many subjects (N) were in each group at the time of last evaluation of that outcome, the appropriate N value for each intervention group was calculated by subtracting the number of patients who withdrew in each intervention group from those randomised to each intervention group.

Authors were written to (by mail, fax and/or electronic mail) to clarify details of randomisation and/or request missing outcome data. Attempt was made to send requests to correct current addresses by searching MEDLINE, EMBASE and hospital World Wide Web (WWW) sites for up-to-date contact details.

#### Assessment of risk of bias in included studies

Two reviewers (NPA and JB) who were blinded to the author's names, institution and funding sources independently assessed each study for methodological quality. The trials were scored using the Cochrane approach:

Grade A: adequate allocation concealment Grade B: unclear allocation concealment Grade C: clearly inadequate concealment

The methodological quality of included studies was also assessed using a 5 point scoring instrument (Jadad 1996):

- a) Was the study described as randomised? (yes=1 no=0)
- b) Was the study described as double blind? (yes=1 no=0)
- c) Was there a description of withdrawals and dropouts? (yes=1 no=0)
- d) Was the method of randomisation well described and appropriate? (yes=1 no=0)
- e) Was the method of double blinding well described and appropriate? (yes=1 no=0)
- f) deduct 1 point if method of randomisation or blinding inappropriate

Inter-rater agreement was measured using the kappa statistic. Disagreement was resolved by consensus.

#### **Assessment of heterogeneity**

Heterogeneity of effect size across studies pooled was calculated using a chi square test, with P< 0.05 used as the cut-off level for significance. Sensitivity analyses were performed on the basis of methodological quality. Results were re-analysed using studies of only the highest quality scores (Jadad 3 to 5). Subgroup analyses based upon patient age, delivery device and study duration were planned.

#### **Data synthesis**

A weighted treatment effect across trials was calculated using the Cochrane statistical package RevMan 4.0.3 with MetaView 3.1. For continuous outcomes, a weighted mean difference (WMD) or standardised mean difference (SMD) was calculated as appropriate. For dichotomous outcomes a relative risk (RR) was calculated. Pooled treatments effects are expressed with their 95% confidence intervals (95% CI). A fixed effect model was used throughout. A number of a priori conditions were established regarding the comparisons made:

- 1. Studies were distinguished as those in which patients were a) not treated with regular oral corticosteroid (OCS), b) dependent upon regular oral steroid treatment prior to study. Trials involving OCS-dependent patients in which the efficacy of inhaled corticosteroid (ICS) is being assessed may have an 'OCS down-titration' design using reduction in the use of oral steroid as an outcome measure, whilst maintaining a given level of asthma control. However, studies in which patients were not treated with regular OCS are more likely to have a design aimed at detecting improvements in asthma control. It is inappropriate to combine trials with these different designs and objectives.
- 2. The results of parallel and crossover trials were not pooled.

3. It was anticipated that measures of bronchial hyperresponsiveness (PD20 FEV1, PC20 FEV1) would often be reported as geometric means. Presentation of results in this way indicates that data has been logarithmically transformed prior to analysis by investigators to take account of a skewed distribution. Data for such outcomes was only pooled across studies where the mean and standard deviation of logged values (from which geometric means are derived) could be calculated.

## RESULTS

## **Description of studies**

#### Results of the search

Stage 1 electronic search: 6494 citations retrieved, 2162 original citations

Stage 2 electronic search:

BDP register BUD register

Electronic citations 1149 1036

Citations excluded from abstract description: Not RCT 379 331 Not chronic asthma in humans 190 195 Not concerned with ICS treatment 177 129 Clearly not concerned with BDP v BUD 113 40

Papers retrieved in full text 290 341

Excluded after full paper retrieval: Not RCT 94 46 Not involving BDP v BUD comparison at 176 275 equal nominal daily dose

Included studies 20 (same studies identified from both registers)

One study (Greefhorst 1992) was identified after searching the bibliographies of included studies, three studies (Dal Negro 1997, Hamalainen 1998, Micheletto 1997) were identified by searching the proceedings of respiratory society meetings.

#### **Included studies**

24 publications were identified met the inclusion criteria for the review representing 24 studies. Publication dates ranged from 1982 to 1998. Details of the trials are in the table of Characteristics of Included Studies. Four studies were identified that were published in abstract form only (Dal Negro 1997, Greefhorst 1992, Hamalainen 1998, Micheletto 1997). No outcome data for these studies is available. The studies have been included as further information may be available at a future date when the review is updated. Two further publications (Hernandez 1995, Lee 1995) require translation and are awaiting assessment. We would also like to draw the reader's attention to the six further citations (Baxter-Jones 2000, Brand 2001, Dal Negro 1999b, Jager 2000, Kraszko 1999, Reichel 2001) listed under Studies awaiting assessment. Due to unforeseen delays in the publication of this review, a number of potentially relevant trials have been identified after an up dated search of the electronic sources from April 1999 - August 2001. These studies will be fully evaluated and included as appropriate in a future update at the earliest possible opportunity.

#### **Study Populations**

The majority of studies were conducted in Europe (Belgium, Denmark, Finland, France, Germany, Ireland, Italy, Sweden, The Netherlands, UK). One study (Springer 1987) was conducted in Israel. One study (Baran 1987) was conducted in a residential centre for asthmatic children; in one study (Greefhorst 1992) the setting was unclear. All other studies were conducted in a hospital outpatient clinic setting. Six studies were in children, 18 in adults.

#### Diagnosis of asthma

In 17 studies (71%) there was no clear indication of the criteria upon which a diagnosis of asthma was made and appears to have been at the discretion of the investigators. In one study (Boe 1989) diagnosis was based upon ATS 1962 criteria. In three studies (Bisgaard 1988, Ebden 1986, Petrie 1990) diagnosis was supported by demonstrable reversibility of clinic PEF or FEV1 following inhaled beta2 agonist; in three studies (Brambilla 1994, Svendsen 1992, Tjwa 1995) diagnosis was supported by demonstration of a 15% or greater reversibility in FEV1 following inhaled beta2 agonist or variability in FEV1 in combination with bronchial hyperresponsiveness (BHR) to methacholine or histamine.

#### Treatment with oral corticosteroids

In three early studies (Rafferty 1985, Stiksa 1982a, Stiksa 1982b) requirement for oral corticosteroid (OCS) for asthma control in the form of prednisolone was an inclusion criterion. In one study (Stiksa 1985) a proportion of enrolled patients were OCS-treated, although this was not a specific inclusion criterion. In 20 studies regular OCS treatment was either a specific exclusion criterion or it was clear from baseline demographic characteristics that patients were not receiving regular OCS prior to the study.

## Asthma severity and asthma control

Asthma severity may be defined in terms of the amount of medication required to achieve a certain level of asthma control, or in terms of the frequency of symptoms experienced and/ or the degree to which FEV1 (% predicted) is depressed before commencing regular prophylactic therapy. Asthma control is best considered the degree to which patients symptoms are uncontrolled and/or the degree to which their FEV (% predicted) is depressed, irrespective of the amount/type of prophylactic medication prescribed. The characteristics of the included studies in terms of these factors have been listed in Table 1, Table 2 and Table 3. Baseline FEV1 (% predicted) and symptom frequency were reported infrequently, so, in the majority of studies, it was not possible to determine the level of asthma control at randomisation.

## Study design

Five studies (Bisgaard 1988, Brambilla 1994, Dal Negro 1997, Micheletto 1997, Selroos 1994) were parallel group studies. Nineteen studies (79%) were of crossover design.

Only two crossover design studies (Bjorkander 1982a, Tjwa 1995) incorporated a washout (one week or four weeks respectively) between treatment periods. No other crossover studies had a washout period between active treatments. In only two of these (Pedersen 1988, Petrie 1990) was it stated if carryover/sequence effects were tested for and excluded. In all the remaining crossover

studies without washout, no comment was made regarding this possible confounding factor.

The length of treatment period varied. Twelve studies (50%) had treatment periods of between two and four weeks, 10 studies (42%) had treatment periods of between six and 12 weeks. The longest study (Selroos 1994) had an effective treatment period of two years. The only study enrolling OCS-dependent patients (Rafferty 1985) had a complex and unique trial design with treatment periods of variable length and is discussed separately below.

As an inclusion criterion for the review, all studies had to assess equal nominal daily doses of BDP and BUD. Ten studies (42%) assessed 400 mcg/d, seven studies (29%) assessed 800 mcg/d. Two studies (Ebden 1986, Svendsen 1992) assessed higher daily doses i.e. BDP 1500 mcg/d v BUD 1600 mcg/d. Only one study (Baran 1987) assessed 200 mcg/d. Two parallel group studies (Brambilla 1994, Selroos 1994) used a 'dose down-titration' design in which ICS dose reduction was attempted at regular intervals during the randomised treatment phase to the minimal effective dose. Conversely, one study (Bisgaard 1988) used a 'dose-escalation' design whereby patients were randomised to receive BDP or BUD 200 mcg/d, 400 mcg/d then 800 mcg/d each for 4 weeks in succession. Only one study of crossover design (Boe 1989) incorporated more than two treatment periods: BDP 400 mcg/d, BUD 400 mcg/d, BDP 1000 mcg/d and BUD 800 mcg/d.

Eight studies (33%) used a MDI to deliver both BDP and BUD. Different types of delivery device were used to deliver each ICS in 16 studies (66%).

#### Outcomes

A wide range of efficacy and safety outcomes was assessed. A number of reported outcomes have not been considered. These include plasma ACTH and growth hormone levels (Nicolaizik 1994), and 24 hour urinary tetrahydrocortisone glucosiduronate and tetrahydrocortisol glucosiduronate levels (Springer 1987).

## Risk of bias in included studies

Methodological quality of included studies was variable. Only 10 studies (42%) were double blind. 19 studies (79%) provided adequate descriptions of numbers of patients withdrawn and the reasons for withdrawal. As assessed by the Jadad scoring method 15 studies (63%) achieved a score of 3 or 4; no studies achieved a maximum score of 5. In only four studies (17%) was allocation concealment clearly employed. In all other studies allocation concealment was unclear.

#### Effects of interventions

A significant amount of data for reported outcomes could not be included in the meta-analysis. This included all data for the four studies published in abstract form only, and a number of outcomes reported in crossover studies published as full journal papers. These data are listed in Table 4. In most cases a narrative description of these results has not been made. This is because the study was either a) low methodological quality (Jadad score 2 or less) and/or b) it was not stated whether carryover effects had been excluded in the case of crossover studies (see Discussion). However, an exception has been made in the case of Pedersen 1990. This was the only fair quality crossover study (Jadad score

3) in which significant carryover effects had been excluded by the investigators. The results are reported in narrative form below.

#### **ASTHMA NOT TREATED WITH ORAL STEROIDS**

#### **CROSSOVER STUDIES**

#### Spirometry

FEV1 (litres) was reported in six studies (227 subjects). FEV1 (% predicted) was reported in two studies (74 subjects). No significant difference between BDP and BUD was apparent. Studies that reported FEV1 using different measurement scales were pooled in order to increase the power of the analysis (eight studies, 301 subjects). The pooled treatment effect was expressed as a standardised mean difference. No significant difference between BDP and BUD was apparent: SMD -0.15, 95% CI -0.38 to 0.07. A similar result was found for FVC (litres), FVC (% predicted), and FVC (litres, % predicted combined), with no significant difference between BDP and BUD.

#### Peak expiratory flow rate (PEF)

Six studies (220 subjects) reported diary card recorded morning PEF (L/min). One study (Field 1982, 54 subjects) reported diary card recorded PEF (% predicted). No significant difference between BDP and BUD was demonstrated, either when outcomes were considered according to the measure used, or when studies were pooled with the treatment effect expressed as a standardised mean difference: SMD -0.04 (95% CI -0.28 to 0.20).

One study (Springer 1987, 20 subjects) reported clinic measured PEF (% predicted). No significant difference between treatments was demonstrated. Five studies (111 subjects) reported evening PEF. No significant difference between BDP and BUD was apparent, WMD -5 L/min (95% CI -32 to 21 L/min).

#### **Symptoms**

A variety of symptom scores were reported. These included daily, daytime, night-time, morning and evening cough, breathlessness and wheeze scores. No significant difference between treatments was apparent for any of these symptom measures. Those studies reporting daytime breathlessness, morning breathlessness and daily symptom scores were pooled (six studies, 256 subjects). No significant difference between BDP and BUD was apparent: SMD 0.06 (95% CI -0.18 to 0.31). Studies reporting night-time breathlessness and evening breathlessness scores were pooled (three studies, 134 subjects). Again, no significant difference between treatments was apparent: SMD -0.09 (95% CI -0.43 to 0.25).

## Rescue beta-2 agonist use

Numerical data for rescue beta2 agonist use was only reported in two studies. Tjwa 1995 assessed daytime and night-time use; Willey 1982 assessed morning and evening use. No significant differences between treatments were apparent.

### Bronchial hyper-responsiveness (BHR)

Only one study with numerical data (Tjwa 1995) assessed histamine BHR. This study in adult patients was of fair methodological quality (Jadad score 3), and assessed the effects of BDP and BUD at a nominal daily dose of 400 mcg, with BUD administered via Turbohaler DPI and BDP via a Rotahaler DPI. A significantly lower histamine BHR (expressed as log 10 PC20 FEV1) was apparent after BUD treatment for eight weeks compared to BDP, WMD 0.43 log 10

PC20FEV1 (95% CI 0.05 to 0.81 log10 PC20 FEV1). This translates into a 1.4 fold greater doubling concentration of histamine required to produce a 20% fall in FEV1 compared to BDP (95% CI 0.4 to 2.4 doubling concentrations, investigator's analysis).

#### Hypothalamo-pituitary adrenal axis (HPA) function

Three studies (118 subjects) reported morning plasma cortisol. Two studies (76 subjects) reported plasma cortisol following a short cosyntropin test. No significant differences between BDP and BUD treatment groups were evident. In a single crossover study (Pedersen 1988), conducted in children and of fair methodological quality (Jadad score 3) 24 hour urinary free cortisol excretion was assessed. In this study subjects treated with BDP 800-1200 mcg/d had significantly lower 24 hour urinary cortisol levels compared to BUD 800-1200 mcg/d: BDP 7.6 nmol cortisol/mmol creatinine/day v BUD 10.2 nmol cortisol/mmol creatinine/day P<0.01.

#### Local oral side effects

The incidence of local oral side effects was reported in a number of crossover studies (Baran 1987, Boe 1989, Ebden 1986, Petrie 1990, Svendsen 1992). However, interpretation of the results is extremely difficult. In each study, the incidence of side effects was reported by treatment (BDP or BUD), rather than by individual treatment period. It was not stated if, in the case of a patient experiencing an adverse event during the first period of the trial when receiving one ICS, this had resolved by the point of crossover. Because none of the studies incorporated washout periods, this was especially unclear. In summary, the data regarding local oral side effects from the crossover studies comparing BDP to BUD are uninterpretable.

## Sensitivity analyses

No heterogeneity in effect size was present when studies were pooled for any outcome. Sensitivity analyses were undertaken by re-analysing outcomes and only including studies with a Jadad score of 3 or greater. This eliminated two studies (Bjorkander 1982a, Nicolaizik 1994). This did not result in a significant change in the size or direction of the treatment effect for any reported outcome.

### Subgroup analyses

Subgroup analyses based upon nominal daily dose, age, study duration, delivery device and asthma control did not identify any groups who appeared to preferentially benefit.

## PARALLEL GROUP STUDIES: DOSE-DOWN TITRATION DESIGN

Two parallel group studies adopted a dose down-titration design. Both were non-blinded open studies of variable methodological quality. One study (Brambilla 1994) had a Jadad score of 2, the other (Selroos 1994) had a Jadad score of 3. Both were undertaken in adult asthmatics treated with BDP 1000 mcg/d or greater. In one study (Brambilla 1994) patients entered a 4-week run-in phase during which time they were maintained on the same daily dose of BDP that they received before entering the study. In Selroos 1994 study patients entered a two-year run-in period during which time the minimal effective dose of BDP was established in order to maintain the 'best possible level' of symptom control, such that patients were free of symptoms. Patients were randomised to either 12 weeks of treatment (Brambilla 1994) or two years of treatment (Selroos 1994). During this time the daily dose of ICS was down-titrated following pre-defined symptom-based criteria whilst maintaining symptom control. The primary outcome measure in both studies was the end of study daily ICS dose. A significantly lower daily dose of BUD was required to maintain symptom control: WMD 444 mcg/d (95% CI 332 to 556 mcg/d). As would be anticipated given a trial design aimed at maintaining optimal control there were no significant differences in FEV1, PEF, rescue beta2 agonist use or withdrawals due to asthma exacerbation. There were no significant differences between treatments with regard to the incidence of local oral side effects (hoarseness/sore throat or Candidiasis).

#### **PARALLEL GROUP STUDIES: DOSE ESCALATION DESIGN**

A single parallel group study of three months duration in children (Bisgaard 1988), of high methodological quality (Jadad score 4) had a dose escalation design. Subjects were randomised to treatment with BDP or BUD. Patients in each randomised arm received 200 mcg/d, 400 mcg/d then 800 mcg/d for four week periods in succession with no washout between treatments. Patients were therefore randomised according to ICS, but not by daily dose of ICS. Outcomes reported included 24-hour urinary free cortisol excretion and plasma cortisol 30 min post 250 mcg i.v. tetracosactrin. No statistically significant difference between BDP and BUD were apparent for either outcome.

#### **ASTHMATICS TREATED WITH ORAL STEROIDS**

#### **CROSSOVER STUDIES: OCS-SPARING STUDY DESIGN**

One crossover study (Rafferty 1985) assessed the relative efficacy of BDP and BUD at a nominal daily dose of 800 mcg/d in adult patients treated with and dependent upon oral prednisolone at dose of 5mg/d or greater. This study was of fair quality (Jadad score 3). The use of a crossover design to assess OCS sparing efficacy is unique to this study. During each treatment period the daily dose of prednisolone was down titrated until asthma symptoms had deteriorated to 'an unacceptable level', although no a priori defined scheme was used to do this, with the decision to down-titrate dose appearing to have been at the discretion of the investigator. The treatment period for each patient concluded at the point of loss of symptom control. Following this, patients entered a 'washout' period during which time their pre-study dose of oral prednisolone was administered for four weeks before entering the second period of the study on the second ICS. Mean reduction in daily dose of oral prednisolone in BDP treated patients was 2.65 mg/d compared to 1.80 mg/d in BUD treated patients, with difference in reduction between groups of 0.85 mg/d in favour of BDP being statistically significant.

## **CROSSOVER STUDIES: NON OCS-SPARING STUDY DESIGN**

Three studies enrolled OCS treated patients, but did not assess OCS-sparing effects as part of the study design. In two studies (Stiksa 1982a, Stiksa 1982b) requirement for OCS therapy was an inclusion criterion. In one study (Stiksa 1985) OCS treatment was not an inclusion requirement, but 10 out of 27 subjects were being treated with oral prednisolone at the time of enrolment. All studies were of fair methodological quality (Jadad score 3). The outcomes for these studies were pooled (3 studies, 144 subjects). No significant difference between BDP and BUD was apparent for morning PEF, evening PEF, daytime or night-time breathlessness scores, sleep disturbance scores or rescue beta2 agonist use.

#### DISCUSSION

This systematic review has assessed the randomised controlled trials that compared BDP and BUD at equal nominal daily dose, with the objective of assessing their relative efficacy and safety. 24 trials with 1174 children and adults were included.

### **RELATIVE EFFICACY**

The trials designed to assess the relative efficacy of inhaled BDP and BUD in non oral steroid treated asthmatic patients have been mainly of two period crossover design. Children and adults are represented, with daily doses of ICS ranging from 400 mcg/d or less to 1000 mcg/d or greater. Treatments were compared over a period of up to five weeks. A meta-analysis of the available data from these trials showed no significant difference between BDP and BUD when considering FEV1, morning PEF, or symptoms. Rescue beta2 agonist use was reported infrequently and the two trials that did report it used different scoring systems. Individually, they did not demonstrate a statistically significant difference between treatment groups.

The results of this analysis require cautious interpretation for the following reasons. Particular strengths of a crossover design relate to the fact that subjects recruited to the trial effectively act as their own controls. This results in a) efficiency in design as only half as many subjects are required in order to achieve the same degree of statistical power as an equivalent parallel design study and b) the effect of inter-individual variation in response to treatment is reduced, which may otherwise mask a true treatment effect. Unfortunately this design has some serious limitations when assessing the effects of relatively long acting interventions such as inhaled corticosteroids. Although most of the trials in this group were of fair methodological quality according to recognised grading systems, including that developed by Jadad, only two out of 19 trials had a washout of any length between treatment periods. Inhaled corticosteroids almost certainly exert an action that persists over days if not weeks after they have been discontinued. When the performance of long acting agents are assessed in trials of crossover design, there is also a concern that the effects of treatment administered in the first period of the trial may persist into, and modify the effects of any active agent administered in the second period of the trial. This so called 'carryover' or 'sequence' effect will influence the results of the study and lead to biased judgement concerning the relative efficacy and safety of the agents being assessed. In situations where the control intervention is inactive or a placebo, this effect will tend to produce an under estimate of the efficacy of the active treatment. In trials when two active treatments (such as BDP and BUD) are studied the influence of carryover effects are unpredictable. It is possible that a less effective drug could falsely appear to be the more effective one, if for example the carryover effect was strong and confined to the truly more effective drug. There are well-established statistical methods for assessing the presence or otherwise of carryover effects and excluding them. However a statement as to whether such tests were undertaken was rarely reported.

These considerations somewhat undermine the results of the individual trials and necessitate additional caution in drawing conclusions from any meta-analyses. When considering the crossover trials, bronchial hyper-responsiveness to histamine was the only outcome for which a significant difference between BDP and BUD was reported. This was from a single study (Tjwa 1995)

in which BUD 400 mcg/d was delivered via the Turbohaler DPI and BDP 400 mcg/d was delivered via the Rotahaler DPI. This study incorporated a four-week washout period and the investigators excluded carryover effects, so this study is not subject to the criticisms as discussed above. Caution still needs to taken in interpreting these results because neither physicians nor patients were blinded to treatment allocation. The study was sponsored by Astra, the manufacturers of the Pulmicort Turbohaler, so the possibility of bias in favour of BUD cannot be excluded. It also possible that the observed difference in treatment effect was due to the delivery characteristics of the two dry powder delivery devices, rather than differences in the efficacy of BDP and BUD.

Only two parallel group design studies (Brambilla 1994, Selroos 1994) assessed the relative efficacy of BDP and BUD in non oral steroid treated subjects and had usable data. These studies had fundamentally different objectives to the studies of crossover design. They used a dose down-titration design to compare the doses of BDP and BUD needed to maintain a good level of asthma control. A significantly lower dose of BUD was required to maintain control compared to BDP: WMD 444 mcg/d (95% CI 332 to 556 mcg/ d). No heterogeneity in effect size was apparent between these studies, which differed greatly in duration (12 weeks and two years). It is important to appreciate that the drugs were administered using different delivery devices. In both studies, BUD was delivered by the Turbohaler DPI and BDP was delivered either by an MDI (Brambilla 1994) or an MDI+Volumatic spacer (Selroos 1994). Unfortunately there were no studies of this type that compared drugs delivered by the same type of delivery device. As with the study by Tjwa 1995, a weakness common to both of these trials lies in the fact neither physicians nor patients were blinded to treatment allocation. Because both studies were sponsored Astra who manufacture the Pulmicort Turbohaler the possibility of systematic bias in favour of BUD is a possibility that cannot be excluded.

The relative oral steroid sparing efficacy of BDP and BUD was only assessed in one study (Rafferty 1985). In an approach unique in the inhaled corticosteroid literature, the relative oral prednisolone sparing effect of two interventions was assessed in a trial of crossover design. This study has two significant flaws. Firstly, the minimal effective dose of prednisolone was not established for each patient either at the beginning of the study, or during the 'washout' phase between treatment periods when each patient received 4-6 weeks of treatment with prednisolone. Enrolling subjects who are over treated with oral prednisolone could lead to an overestimate of the absolute prednisolone sparing efficacy of both BDP and BUD and lead to distortion in assessment of their relative effects. The second problem concerns the system used to taper the prednisolone dose. Dose reduction was attempted at regular intervals throughout each treatment period, until the point at which asthma symptoms deteriorated to 'an unacceptable level'. However no a priori definition for unacceptable symptoms was used. This could have led to a large degree of variation in the thresholds used by individual investigators in determining whether or not to continue dose reduction or to stop further dose reduction when assessing patients at clinic visits. The study was double blind and patients were randomised to each treatment sequence so these variations should have affected all patients equally. However in a study of small size (40 subjects) this factor may have had an unpredictable effect on the overall assessment of relative efficacy of the two inhaled steroids.

#### **RELATIVE SAFETY**

24 hour urinary free cortisol and plasma cortisol levels following short tetracosactrin test were assessed in the single high quality parallel group dose, escalation design study (Bisgaard 1988) undertaken in children. No significant difference between BDP and BUD delivered by identical delivery device (MDI) were apparent.

No significant difference in post tetracosactrin plasma cortisol levels or basal morning plasma cortisol levels were apparent when BDP and BUD were compared in trials of crossover design. Because of an absence of washout periods and elimination of carryover effects in the trials reporting these outcomes, the same caution in interpretation needs to be taken for the reasons outlined above. Only one crossover study (Pedersen 1988) reported a sensitive measure of HPA function in the form of 24 urinary cortisol excretion corrected for creatinine. It should be noted that although a range of daily doses of ICS were assessed in this study (800-1200 mcg/ d) individual children were randomised to receive identical daily nominal doses of BDP or BUD in each period of the crossover study, via identical delivery devices (MDI). Carryover effects were tested for and excluded in this study, despite the fact that a washout was not used. This study appears to be free of the limitations concerning the majority of crossover design studies. Although these differences are statistically significant, their clinical significance is uncertain. The concern regarding ICS use and HPA function, especially in children, is the long-term risk of adrenal insufficiency/crisis at times of stress. The predictive value of differences in results obtained in any of the available sensitive measures when comparing inhaled steroids and long term risk of adrenal insufficiency is unknown.

## **STUDY POWER**

The primary purpose of these studies was never clearly defined - i.e. whether their objective was to determine therapeutic superiority or equivalence. This is important since the process of hypothesis testing is different between the two types of study, most noticeably in the use of upper and lower limits of equivalence in equivalence studies. For statistical reasons, equivalence studies usually have to be larger than superiority studies. None of these points were discussed in the trials included here, and all were too small to have been adequate for a test of equivalence.

#### **AUTHORS' CONCLUSIONS**

## Implications for practice

Current asthma guidelines (BTS 1997, GINA 1995, NHLBI 1997) assume beclomethasone and budesonide are equally effective, such that for each defined level of asthma severity, the recommended doses are the same. However, there is little reliable evidence from randomised controlled studies to support this conclusion, and none to refute it. There are some data which suggest that budesonide via a Turbohaler is more effective than BDP delivered by either a Rotahaler or a MDI with or without spacer, but this difference may be due to the delivery device rather than the drug and is not sufficient to warrant any change in guideline recommendations.

## Implications for research

There is a place for a large, parallel group randomised controlled trial to test the equivalence of BDP and BUD. Ideally this would include treatment arms assessing low dose ICS (400 mcg/d or less) and high dose ICS (1000 mcg/d or greater) in asthmatic children and adults. Currently available dry powder delivery devices differ for BDP and BUD. To assess relative drug efficacy without the confounding influence of differences in inhaler performance the newer non-CFC propellant metered dose inhalers could be used as a standardised delivery device if both drugs become available in this form. An intervention period of 6 months or longer would allow assessment of important outcomes such as asthma exacerbation rates, hospital admissions, days lost from work/school and heath status which have not been reported in any studies to date.

#### ACKNOWLEDGEMENTS

We would like to thank Anna Bara for running the initial electronic search and Steve Milan for assistance with statistical methods. We also like to acknowledge the authors who kindly responded to requests for additional information regarding their studies even in cases where information was not available including Dr M Boorsma, Dr C Brambilla, Dr P Ebden, Professor S Godfrey, Dr S Pedersen, Dr S Selroos, Dr G Stiksa, Dr UG Svendsen, Dr MKT Tjwa, Professor JO Warner and Dr RF Willey.

## Baran 1987

Methods Setting: Belgium, residential centre for asthmatic children

Length of intervention: 3 weeks Design: crossover, no washout

Randomisation: yes, method not stated Allocation concealment: unclear

Masking: double blind Excluded: not stated Withdrawals: stated (none)

Baseline characteristics: no tabulated demographic data

Jadad score: 3

Participants 21 children: 15M 6F

Age range: 4-14 Inclusion criteria:

<sup>\*</sup> Indicates the major publication for the study

Baran 1987 (Continued)	Children suffering from chronic asthma and using inhaled corticosteroids to control their disease No other criteria given Exclusion criteria: None stated
Interventions	BDP: 50 mcg 2puffs 2xdaily (200 mcg/d) via MDI BUD: 50 mcg 2puffs 2xdaily (200 mcg/d) via Inhalet spacer
Outcomes	FEV1 FVC Morning PEFR Evening PEFR Daytime breathlessness score

Night-time breathlessness score Daily cough score Sleeping difficulties score

Sleeping difficulties score 8 am plasma cortisol

Incidence of oropharyngeal Candidiasis

Both active treatment arms demonstrated significant improvements compared to non-randomised placebo arm for morning PEFR, evening PEFR and symptom scores.

Notes No reply from author to clarify details of randomisation method

Not stated if carryover effects were tested for.

Significant improvements in morning PEFR, evening PEFR and symptoms compared to non-ran-

domised placebo treatment period at end of study.

Brambilla 1994

Methods Setting: multicentre study France, hospital outpatient clinic

Length of intervention: 12 weeks

Design: parallel group, dose down-titration Randomisation: yes, method not stated Allocation concealment: unclear

Masking: none Excluded: not stated Withdrawals: stated

Baseline characteristics: comparable

Jadad score: 2

Participants 146 adults

Inclusion criteria:

Recurrent acute exacerbations of breathlessness and wheezing

15% or greater variability in FEV1

Bronchial responsiveness to methacholine or histamine (PD20 FEV1 2mg or less)

Receiving inhaled BDP 1000-2000 mcg/d for at least 6 months

Exclusion criteria:

Airways disease other than asthma Smoker > 5 packs cigarettes per year Significant co-existent disease

Interventions BDP: 800 to 2000 mcg total daily dose via MDI

BUD: 800 to 1600 mcg total daily dose via Turbohaler DPI

Outcomes FEV1

Morning PEFR Evening PEFR

Number of puffs of inhaled corticosteroid per day

Number asthma exacerbations/week

Number night awakenings requiring beta2 agonist use/week

Daily beta2 agonist use (puffs/day) Withdrawal due to asthma exacerbation Incidence of local oral side effects

Notes Reply from author but unable to clarify details of randomisation procedure.

Dose down titration study design: patients were randomised to receive either BDP or BUD at a dose considered to be equivalent to their pre-study dose of BDP. BDP 250 mcg/puff via MDI was considered

equivalent to BUD 200 mcg/actuation via Turbuhaler DPI.

During the study daily dose of ICS was reduced according to pre-defined criteria based on experience

of asthma symptoms in the week prior to assessment.

## **Greefhorst 1992**

Methods	Setting: muticentre study.	The Netherlands, primary	care or hospita	l outpatient setting unclear	٢

Length of intervention period: 6 weeks Randomisation: yes, method not stated Allocation concealment: unclear Design: crossover, no washout

Masking: none Excluded: not stated Withdrawals: not stated

Baseline characteristics: no demographic data presented

Jadad score: 1

Participants 145 adults

Inclusion criteria:

Adult asthmatic patients already treated with inhaled corticosteroids

No further details Exclusion criteria: No details

Interventions BDP: 200 mcg 2xdaily (400 mcg/d) via Rotahaler DPI

BUD: 200 mcg 2xdaily (400 mcg/d) via Turbuhaler DPI

Outcomes Morning PEFR

Evening PEFR

Asthma symptom score Rescue beta2 agonist use

Notes Study in abstract form only.

No reply from author to clarify details of randomisation method used, further inclusion/exclusion crite-

ria, patient withdrawals or data for outcomes. Not stated if carryover effects were tested for.

#### Nicolaizik 1994

Methods Setting: UK, hospital outpatient clinic

Length of intervention: 2 weeks Design: crossover, no washout

Randomisation: yes, method not stated Allocation concealment: unclear

Masking: none Excluded: not stated Withdrawals: stated

Baseline characteristics: no tabulated demographic data presented

Jadad score: 2

Participants 14 children: 11M 3F

Age range: 8 to 14 years Inclusion criteria:

Asthma inadequately controlled on inhaled sodium cromoglycate and beta2 agonists and/or optimal

doses of slow release oral theophyllines

Reliable in medication compliance, diary card recording, use of MDI

Exclusion criteria:

Any steroid medication within the last month or regular corticosteroid treatment in the last 12 months.

Significant bronchopulmonary disease other than asthma

Interventions BDP: 50 mcg 4 puffs 2xdaily (400 mcg/day) via MDI

BUD: 50 mcg 4 puffs 2xdaily (400 mcg/day) via MDI

Outcomes FEV1

FVC

Morning PEFR Evening PEFR Daily symptom score

Weekly use of beta2 agonists

Bronchial responsiveness to histamine PC20 FEV1, PD20 FEV1)

## Stiksa 1982a

Methods	Setting: Sweden.	hospital outpatient clinic

Stiksa 1982a (Continued)	Sti	ksa:	1982a i	(Continued)
--------------------------	-----	------	---------	-------------

Length of intervention period: 2 weeks

Randomisation: yes, computer generated sequence

Allocation concealment: yes Design: crossover, no washout

Masking: none Excluded: not stated Withdrawals: stated (none)

Baseline characteristics: no baseline demographic data presented

Jadad score: 3

Participants 27 adults: 19M 8F

Age range: 19-76 years Inclusion criteria:

Asthmatics with 'severe steroid-dependent' asthma

Exclusion criteria: Not stated

Interventions 1. BDP 200 mcg 4xdaily (800 mcg/d)

2. BUD 200 mcg 4xdaily (800 mcg/d)

Delivery device: MDI

Outcomes Morning PEFR

**Evening PEFR** 

Daytime breathlessness score Night-time breathlessness score Sleeping difficulty due to asthma score

Rescue beta2 agonist use

Notes Author confirmed randomisation method and use of allocation concealment.

Author also confirmed that all enrolled patients were oral steroid dependent and that there were no

withdrawals from the study.

Not stated if carryover effects were tested for.

#### FEEDBACK

### Data entry error

#### **Summary**

In table 1.2 the numbers extracted from Willey 1982 do not seem to match the original paper. I believe the numbers should be BDP 2.00 (0.80) and BUD 2.10 (0.80).

No SD values available for any of the above outcomes

#### Reply

Response from Cochrane Airways editorial base: Thank you for bringing this error to our attention. The data has been corrected in analyses 1.2.1, 1.3.1, 2.2.2, 2.3.2, 3.2.1, 3.3.1, 4.2.2 and 4.3.1 and the relevant text in the results section updated to reflect this change. The impact on the results of the analyses over all is negligible.
