ABSTRACT

Autoimmunity following COVID-19 vaccination has been reported. Herein, a 79-year-old man with clinical and immunological features of autoimmune hepatitis type 1 after ChAdOx1 nCoV-19 vaccination is presented. Clinical manifestations rapidly remitted after the instauration of immunomodulatory management. This case, together with a comprehensive review of the literature, illustrates the association between COVID-19 vaccines and the development of autoimmune conditions.

1. Introduction

Infection by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has been commonly associated with liver disorders. The overall frequency of acute liver injury in COVID-19 is about 26.5%, and up to 41.1% of patients present with transaminitis [1]. Levels of glutamic-oxaloacetic transaminase (GOT), glutamic pyruvic transaminase (GPT) [1], and elevated total bilirubin are considered biomarkers of deleterious COVID-19 outcomes [2]. Although a direct assault of SARS-CoV-2 on hepatocytes leading to abnormal liver enzyme levels has been suggested as the main mechanism of liver injury, hepatocytes do not express high numbers of receptors for angiotensin converting enzyme 2 (ACE-2) [2], and direct infection of hepatocytes has not been found [3]. However, residual viral antigens has been detected in hepatic tissue during the convalescent phase, up to 6 months after recovery [4]. Other mechanisms, such as ischemia and cholangiopathy, have recently come under scrutiny [5,6]. In addition, an autoimmune phenomenon could be associated with hepatopathy following SARS-CoV-2 infection [7].

COVID-19 vaccination has been broadly associated with diverse autoimmune conditions. These include autoimmune hepatitis (AIH) [8], myocarditis [9,10], immune thrombotic thrombocytopenia [11],

Guillain-Barré syndrome [12], and giant cell arteritis [13]. Interestingly, patients with autoimmune diseases (ADs) prior to vaccination may exhibit flares following the administration of the biologic [10].

All the above data indicate the possibility of autoimmune phenomena related to SARS-CoV-2 infection or post-vaccination [14]. Although the mechanisms have not been elucidated yet, molecular mimicry is considered one of the major explanation of autoimmunity after vaccination [15,16]. In addition, bystander activation and epitope spreading may also contribute to autoimmunity in those susceptible individuals with ADs or with pre-existing latent autoimmunity [17]. Herein, we present a patient with AIH after AstraZeneca-ChAdOx1 nCoV-19 (AZD1222) vaccination, and a review of similar cases reported in the literature.

2. Case presentation

A 79-year-old man came to the emergency room in September 2021 with a 3-month history of right upper quadrant abdominal pain associated with jaundice, pruritus, acholia, and choloria (Fig. 1A). He denied chronic alcohol abuse, previous hepatotropic virus infections, familial autoimmunity, or additional comorbidities. The patient was not on concomitant medications. He received the ChAdOx1 nCoV-19 vaccine

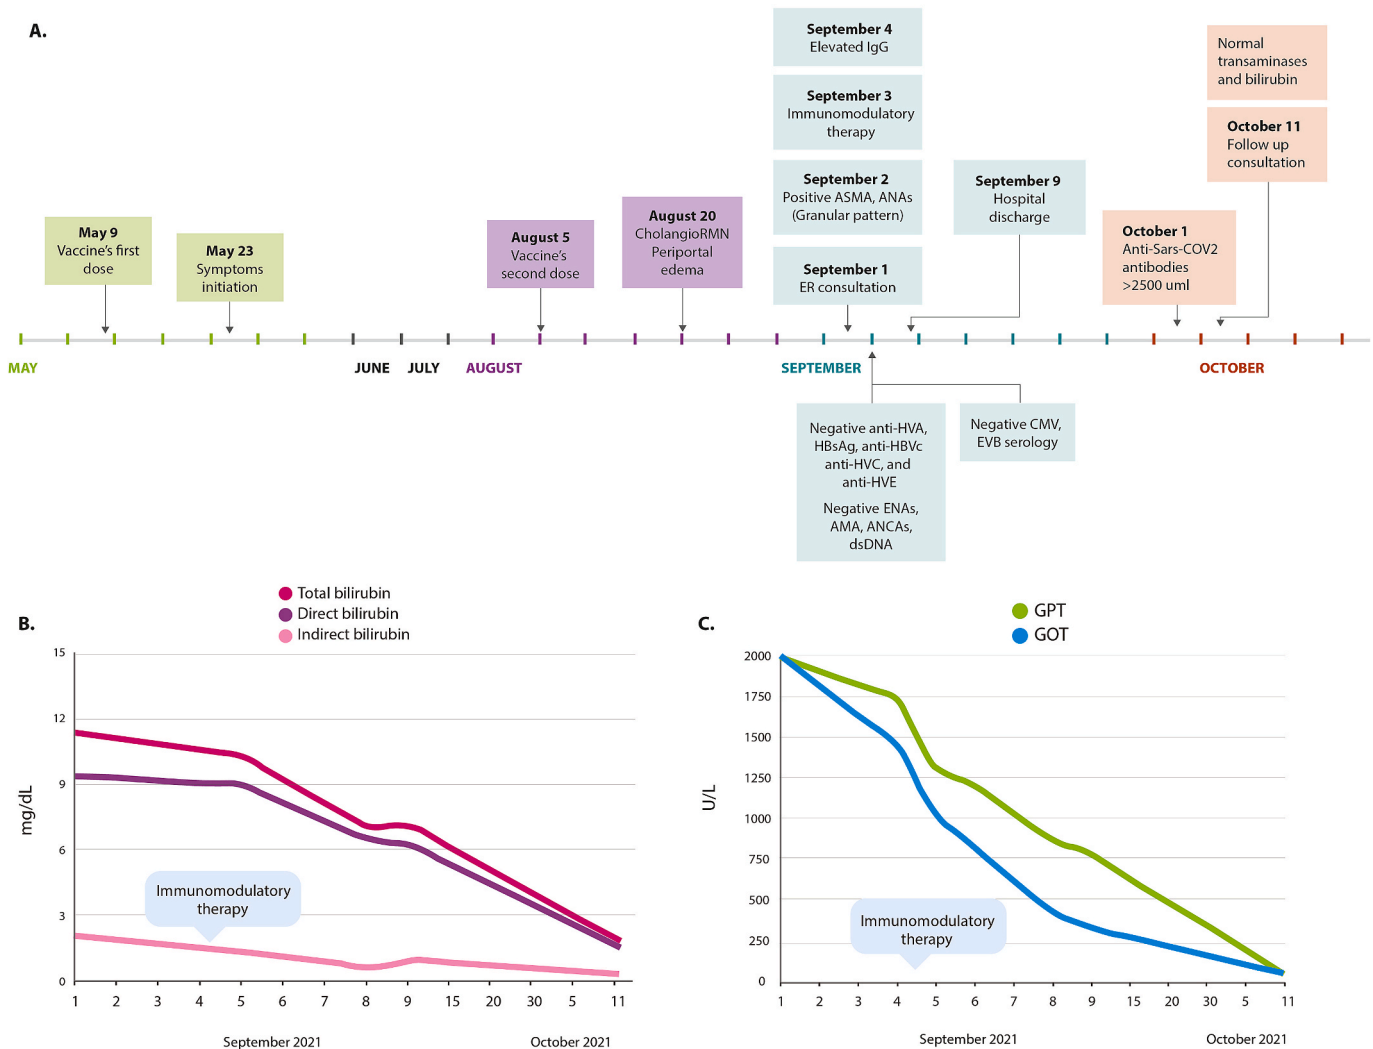

Fig. 1. Clinical timeline and liver function. **A.** Clinical evolution of autoimmune hepatitis. **B.** Levels of total, direct, and indirect bilirubin. **C.** Levels of GOT and GPT. CholangioRMN: magnetic cholangioresonance, anti-HVA: hepatitis A total antibodies; HBsAg: hepatitis B surface antigen; anti-HBc: hepatitis B core antibody; anti-HCV: hepatitis C total antibodies; ENAs: extractable nuclear antigens; AMA: Antimitochondrial antibodies; ANCA: antineutrophil cytoplasmic antibodies; dsDNA: anti-double-stranded DNA antibodies; ER: emergency room; ASMA: anti-smooth muscle antibody; ANAs: antinuclear antibodies; IgG: Immunoglobulin G; CMV: cytomegalovirus; EBV: Epstein-Barr virus; GOT: glutamic-oxaloacetic transaminase; GPT: glutamic pyruvic transaminase.

(AZD1222) on May 9th, 2021, developing the above-mentioned symptomatology 15 days after the first dose. Despite clinical manifestations, he received the second dose on August 5, 2021 (Fig. 1A). The patient was referred to our center on September 1, 2021, from a primary care center.

Examination revealed conjunctival and soft palate jaundice as well as generalized yellow pigmentation of the skin, and mild abdominal tenderness in the right upper quadrant without other significant findings. Blood tests showed mixed hyperbilirubinemia (11.9 mg/dL) with direct bilirubin predominance (9.39 mg/dL) (Fig. 1B), elevated transaminases (GOT 2003 U/L, GPT 1994 U/L) (Fig. 1C), negative hepatotropic viruses' profile (i.e., hepatitis A, B, C, and E), and non-reactive IgG and IgM serology for cytomegalovirus and Epstein-Barr. In addition, the patient had mild lymphopenia ($0.910 \times 10^3/\mu\text{L}$), with normal leukocyte ($5.06 \times 10^3/\mu\text{L}$) and platelet counts ($253 \times 10^3/\mu\text{L}$). Fibrinogen, erythrocyte sedimentation rate (ESR), and C reactive protein were within the normal range.

Given the direct hyperbilirubinemia, an obstructive biliary disease was suspected. Abdominal ultrasound showed edema of the gallbladder walls with a pattern described in acute hepatitis without cholelithiasis. The spleen was normal in size and shape, despite a venous doppler showing increased portal diameter and elevated portal flow velocity (15

mm and 22 cm/s, respectively). The upper gastrointestinal endoscopy showed esophagitis (Forrest III) and chronic antral gastritis. In addition, cholangioresonance showed no biliary obstruction nor additional relevant findings.

After the initial approach, a hepatitis of autoimmune origin was suspected. The patient presented positivity for anti-smooth muscle antibodies (ASMA) (71.0 U, QUANTA Flash – INOVA, San Diego, California), low titer anti-nuclear antibodies (ANAs) (1:80 granular pattern, by indirect immunofluorescence on Hep-2 cells), and elevated IgG (2058 mg/dL, normal range: 650–1600 mg/dL). Other autoantibodies, including anti- RNP, -Sm, -Ro, -La, -mitochondrial antibodies (AMA), -dsDNA, and anti-neutrophil cytoplasmic antibodies, were negative. Anti-SARS-CoV-2 total antibodies after receiving both doses of vaccine were high (>2500 U/mL, threshold for positivity ≥ 0.8 U/mL, by electrochemiluminescence immunoassay, Roche Diagnostics International AG, Rotkreuz, Switzerland).

Liver biopsy, performed on September 20th (after discharge and initiation of immunomodulatory management), showed focal cholestasis and lobulation of the parenchyma, marked ductular proliferation, as well as lymphocytic infiltrate in the portal spaces with the presence of eosinophils, corresponding to a necroinflammatory hepatitis grade 2

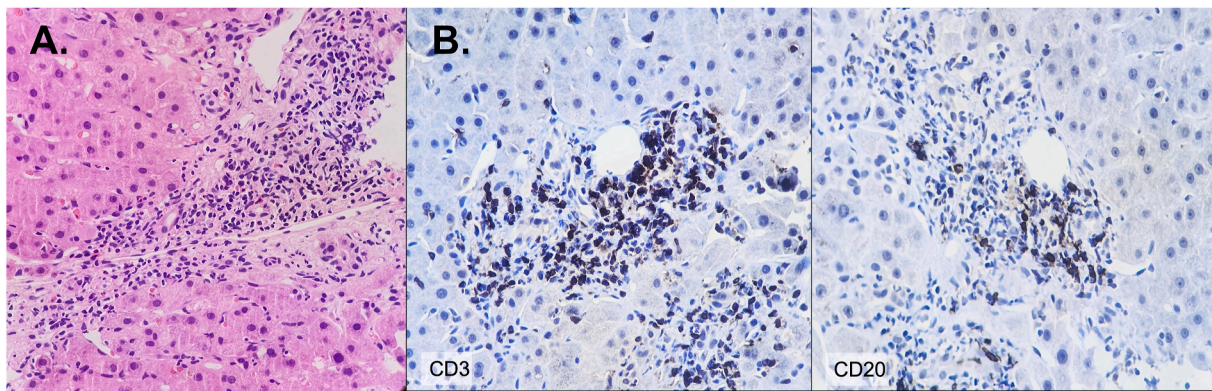

Fig. 2. Liver biopsy histological findings. A. The portal tract shows ductular proliferation, lymphocytic infiltrate, some eosinophils, and interface hepatitis. H&E; X40. B. Immunohistochemistry. Numerous lymphocytes T CD3⁺ cells interspersed with few lymphocytes B CD20⁺ cells. Immunohistochemistry; X40.

stage 2 with focal cholestasis as previously classified [18] (Fig. 2A). Immunohistochemistry staining revealed numerous T CD3⁺ cells interspersed with a few B CD20⁺ cells (Fig. 2B). Altogether, the data indicate fulfillment of the International Autoimmune Hepatitis Group (IAIHG) criteria for type 1 AIH [19], and suggest that it was developed after COVID-19 vaccination, meeting most of the Bradford Hill causality criteria [20,21].

Due to these findings, therapy with hydrocortisone (100mg per day for 3 days) was initiated, switched to prednisone (50mg per day). Azathioprine (50mg per day) was initiated. During the nine days following the establishment of treatment, the patient presented a progressive decrease in the level of liver enzymes (Fig. 1C), and a marked improvement in symptoms, including jaundice, pruritus, and fatigue. Because of favorable clinical evolution, the patient was discharged from the hospital on September 9th. Ambulatory management, including tapering prednisolone of 10 mg per week, was prescribed. In a follow-up consultation on October 11th, the patient's clinical condition continued to improve, as did his liver enzymes (i.e., GOT 39 U/L, GPT 35 U/L), and bilirubin levels (i.e., 1.77 mg/dL).

3. Discussion

Herein, a patient with typical type 1 AIH after the ChAdOx1 nCoV-19 vaccine is described, illustrating the association while causation remains to be confirmed.

AIH is defined as the presence of chronic progressive hepatitis of inflammatory origin [22]. Waldenström described it for the first time in 1951. Currently, mechanisms for AIH development are not fully understood. However, the combination of genetic predisposition and environmental triggers are crucial players in its appearance [22]. Abdominal pain, jaundice, general malaise, and abnormal liver function tests are the most common clinical manifestations. This condition is classified into two groups: Type 1 AIH is positive for ANAs and ASMA, whereas Type 2 AIH is positive for anti-liver and kidney microsome antibodies type 1 (LKM1) and liver cytosol type 1 antibody (LC1), and both types have high IgG levels [22,23].

In the study by Rela et al. [8], two patients developed AIH after the AstraZeneca-ChAdOx1 nCoV-19 (AZD1222) vaccination. Both patients presented with liver profile alterations 2 weeks after the administration of the vaccine and further tests confirmed the diagnosis (i.e., liver biopsy: lymphocyte infiltration, multiacinar hepatic necrosis, periportal neocholangiolar proliferation). However, only one patient presented reactivity to ANAs (1:80) and none of them presented positivity for ASMA, LKM1 nor LKM2. Thus, suggesting that vaccination may induce an acute inflammatory reaction, but production of autoantibodies could take longer.

Findings in liver biopsy correlate with reports of AIH following SARS-CoV-2 vaccination. Necroinflammatory hepatitis was observed in

all cases of AIH following vaccination with Moderna mRNA-1273 COVID-19 [24–29], Pfizer-BioNTech mRNA vaccine [30–33], and AstraZeneca ChAdOx1 nCoV-19 vaccine [8,34]. It has been suggested that portal infiltration with eosinophils correlates with drug-induced liver injury, including vaccines (i.e., Moderna mRNA-1273 and AstraZeneca ChAdOx1 nCoV-19 vaccines) [8,27,28]. This could partially explain the existence of hepatitis following vaccination without positivity for liver-associated autoantibodies (Table 1) [8,10,12,13,24–52].

Although the intramuscular route of administration is safe for lipid nanoparticle (LNP) RNA vaccines, it has been shown that intravenous administration may allow antigen presentation in the liver and lungs, promoting T cell infiltration and damage [53]. Further analyses of LNPs and their likely influence on liver damage are warranted.

Vuille-Lessard et al. [26] reported a case of a 76-year-old woman who developed severe AIH with positive ASMA and elevated IgG after Moderna-mRNA-1273 vaccine administration. In this case, as in ours, it is likely that patients already had an autoimmune background prior to vaccination given the early positivity for IgG autoantibodies. These cases resemble the reported flares following vaccination in patients with overt ADs [10]. In further reports on autoimmunity following COVID-19 vaccination, most of the patients presented with autoimmunity in the first two weeks after vaccination, and some of them presented with early positivity for pathogenic autoantibodies (Table 1). This indicates that vaccines may trigger overt autoimmunity in susceptible individuals or in patients with latent autoimmunity.

This conjecture was also raised by Talotta et al. [54] and Akinosoglou et al. [17] who propose that vaccination does not generate new autoimmune diseases, but rather triggers long-lasting latent autoimmunity. This should call attention to the evaluation of a profile risk prior to the administration of vaccines, including latent and overt autoimmunity, familial autoimmunity, and genetic risk scores [55].

Although the mechanisms associated with vaccination and autoimmunity are still unknown, molecular mimicry has emerged as the most likely process associated with this phenomenon [15,56]. Molecular mimicry is defined as “the similarity between a host epitope and an epitope of a microorganism or environmental agent” [56]. This similarity allows the development of cross-reactivity mediated by T and B cells, which promotes the production of pathogenic autoantibodies that may present different specificities for the human proteome. In addition, intermediate, but not complete homology, is considered the most critical factor for cross-reactivity [56].

The AstraZeneca-ChAdOx1 nCoV-19 (AZD1222) vaccine consists of a replication-impaired chimpanzee adenoviral vector ChAdOx1 that contains the spike (S) protein gene of the virus [57]. Recent studies have shown massive heptapeptide sharing between S protein and the human proteome [15], and other *in silico* studies have suggested the possible influence of viral nucleocapsid protein in the development of cross-reactivity [58].

Table 1
Reported cases of autoimmunity diseases related to COVID -19 vaccination.

Author	Autoimmune disease	Type of vaccine	Time of appearance	Laboratory findings
Iremli et al. [35]	Subacute Thyroiditis	Sinovac – Coronavac vaccine	Case 1: 4 days after 2 doses Case 2: 4 days after 1 dose Case 3: 7 days after 2 doses	Case 1: TSH 0.473 mIU/L, fT4 14.1 pmol/L Negative TPO, Tg and TRAB autoantibodies CRP 100.5 mg/dL ESR 53 mm/hr Thyroid USG bilateral focal hypoechoic areas with decreased blood flow Case 2: TSH 0.01 mIU/L, fT4 5.2 pmol/L, Negative TPO, Tg and TRAB autoantibodies CRP 6 mg/dL, ESR 19mm/hr Thyroid USG bilateral focal hypoechoic areas with decreased blood flow Case 3: TSH 0.9 mIU/L, fT4 13.85 pmol/L, Negative TPO, Tg and TRAB autoantibodies CRP 2.4 mg/dL, ESR 25 mm/hr Thyroid USG bilateral hypoechoic areas with decreased blood flow Normal TSH, T4, and free T3,
Rubinstein et al. [63]	Flare Graves' disease: Thyroid eye disease	Pfizer- BioNTech mRNA vaccine	3 days after 2 doses	Elevated thyroid stimulating immunoglobulin ANA 1:320. Orbit CT scan enlarged inferior and medial recti muscles without tendon involvement or sinus Disease
Lui et al. [49]	Graves' disease	Pfizer- BioNTech mRNA vaccine	5 weeks after 2 doses	TSH <0.02 mIU/L, fT4 66.6 pmol/L, fT3 30.50 pmol/L Thyroid stimulating immunoglobulin level 420% Positive TPO and Tg
Kim et al. [51]	Immune Thrombocytopenia	AstraZeneca ChAdOx1 nCoV-19 vaccine	2 days after 1 dose	Hemoglobin 14.0 g/dL, white blood cell count 7500/ μ L, platelet count 4000/ μ L. Peripheral blood smear: isolated marked thrombocytopenia without schistocytes. Normal clotting times Negative hepatitis B virus surface antigen, anti-hepatitis C virus antibody, VIH, ANAS, dsDNA and urea breath test. Negative anti-heparin/platelet factor 4 IgG
Chittal et al. [50]	Thrombotic Thrombocytopenia	Moderna mRNA-1273 COVID-19	3 days after 2 dose	Platelet count 65,000 platelets/mcL with further decline to 29,000 platelets/mcL Mildly elevated aPTT Positive lupus anticoagulant Positive anti-Platelet factor 4
Jawed et al. [36]	Flare acute immune thrombocytopenia	Pfizer- BioNTech mRNA vaccine	18 Days after the first dose	Platelet count 1000/mcL Peripheral smear thrombocytopenia and normal red blood cell morphology Reticulocyte count 2.2% Prothrombin time 16.2 secs INR 1.5 mg/dL, LDH 310 U/L Negative ANAS
Gaignard et al. [37]	Acute immune thrombocytopenia Autoimmune hemolytic anemia	Moderna mRNA-1273 COVID-19	Case 1 (IPT): 3 days after 1 dose Case 2 (AIHA): 5 days after 1 dose	Case 1: Platelet count 3000/mcL Hemoglobin 15.1g/dL White cells count 6.600/L Case 2: Hemoglobin 8.6g/dL, reticulocyte count $310 \times 10^9/L$, white cells count 11.700/L, platelets count 344000/mcL Elevated transaminases, LDH and bilirubin and decreased haptoglobin MPO, p-ANCA, and c-ANCA negative IAT, IgG- and C3- DAT Positive
Gadi et al. [38]	Autoimmune Hemolytic Anemia	Moderna mRNA-1273 COVID-19	7 days after 1 dose	Hemoglobin 7.1 g/dL, MCV 93 fL, reticulocyte count 15.5%, Total bilirubin 3.7 mg/dL, direct bilirubin 0.8 mg/dL Haptoglobin <8 mg/dL, LDH 746 U/L

Table 1 (continued)

Author	Autoimmune disease	Type of vaccine	Time of appearance	Laboratory findings
Aoun et al. [46]	Cold agglutinin disease	Pfizer- BioNTech mRNA vaccine	3 days after 1 dose	DAT was negative for IgG and C3d. However, eluate prepared from the patient's red blood cell was reactive against all test lockups Hemoglobin of 57 g/L, 10% reticulocytes LDH 671 iu/l Total bilirubin 46.4 $\mu\text{mol/l}$ and direct bilirubin 12.5 $\mu\text{mol/l}$ Peripheral blood film showed marked agglutination Direct antiglobulin test - positive for C3. Negative ANAS, cytomegalovirus, Epstein-Barr virus, HIV, parvovirus, mycoplasma Negative flow cytometric immunophenotyping and protein electrophoresis White blood cell count $1.6 \times 10^9/\text{L}$ and platelet count $11 \times 10^9/\text{L}$
Tabata et al. [45]	Aplastic Anemia	Pfizer- BioNTech mRNA vaccine	4 days after 2 doses	Positive IgG cytomegalovirus and Epstein-Barr - not indicative of virus reactivation Negative hepatitis B, hepatitis C, and VIH Bone marrow biopsy: a hypocellular marrow ESR 32 mm/h, CRP 15.0 mg/L
An et al. [39]	Reactive arthritis	Sinovac – Coronavac vaccine	3 days after 1 dose	Synovial fluid analysis: leukocytes were 20–25/HP, neutrophils 90%, lymphocytes 4%, monocytes 6%, no crystals. Negative gram stain, Negative bacterial cultures Negative ANAS, RF, anti-CCP antibody, and HLA-B27 ESR 42 mm/h, CRP 8.69 mg/dL, IL-6104 pg/mL
Mücke et al. [40]	Immune complex vasculitis	Pfizer- BioNTech mRNA vaccine	12 days after 2 doses	IgG 1549 mg/dL C3 87mg/dL, C4 16.1 mg/L Positive ANAs 1:80, and negative c-ANCA, and p-ANCA Urinalysis: red cell count of 165 cells/mm ³ , urinary albumin to creatinine ratio of 4.9 mg/mmol. Serum creatinine 112 $\mu\text{mol/L}$ Normal serum urea and electrolytes Elevated IgA titres at 3.10 g/L Negative ANAS, ANCA, and rheumatoid factor. Viral antibody titres were negative - acute or chronic infection. Positive TPO and Tg antibodies
Maye et al. [47]	Flare IgA vasculitis	Pfizer- BioNTech mRNA vaccine	24 hours before dose	Negative ANAS, ANCA, and rheumatoid factor. Viral antibody titres were negative - acute or chronic infection. Positive TPO and Tg antibodies
Leber et al. [41]	Acute Thyroiditis and Bilateral Optic Neuritis	Sinovac – Coronavac vaccine	12 hours after 2 doses	Negative ANAs, RF, anti-dsDNA, ENAs, C3/C4, ACE IgA, IgG, IgM and anticardiolipin IgM and IgG antibodies, reactive MOG-IgG (1/320 dilution) TSH 13.2 mIU/L, and normal levels of fT4 Electromyography compatible with demyelinating motor polyneuropathy
Nasuelli et al. [12]	Guillain-Barré syndrome	AstraZeneca ChAdOx1 nCoV-19 vaccine	10 days after 1 dose	Lumbar puncture + CSF with normal white blood cell count and glycorrachia Negative Anti-GM1 IgG-IgM, GQIb IgG-IgM, GM2 IgG-IgM, anti MAG, and anti-GAD Authors did not performed autoantibodies
Tagliaferri et al. [42]	Myasthenia Gravis Crisis	Moderna mRNA-1273 COVID-19	7 days after 2 doses	Hemoglobin 14.8 g/dL, white cell count 6.300/L
Ghielmetti et al. [25]	Acute autoimmune-like hepatitis	Moderna mRNA-1273 COVID-19	7 days after de 1 dose	Platelets 309000/L INR 1.16, GOT 1127 U/L, GPT 1038 U/L, GGT 536 U/L, ALP 192 U/L, Total bilirubin 204.8 $\mu\text{mol/L}$ Hepatotropic virus infections profile negative IgG 19.96 g/L Positive ANAs (1:640, fine speckled pattern), anti-gastric parietal cells, Anti- β -2 glycoprotein IgA, and atypical AMA antibodies Negative anti- β -2 glycoprotein IgM and IgG ASMA, ANCA, SLA, anti-LKM1, anti-LC1, U1-snRNP, SSA/Ro, SS-B/La, CENP-B, Scl-70, Jo-1, Sm, dsDNA, Fibrillarín, RNA Polymerase III, Rib-P, PM-Scl, PCNA, and Mi-2 HLA DRB1*01:01 11:01, HLA DQA1*01:01 05:01, and HLA DQB1*03:01 05:01
Avci et al. [48]	Autoimmune hepatitis	Pfizer- BioNTech mRNA vaccine	30 days after doses	Total bilirubin 11.8 mg/dL, direct bilirubin 9.18 mg/dL GPT 455 IU/ml, GOT 913 IU/ml, GGT 292 IU/ml, ALP 436 IU/ml Hemoglobin 13.3 g/dL, white cell counts 8.530/L Platelets 1999000/mm ³ ANAS 1/100 ASMA 1/100 IgG 4260 mg/dL Hepatotropic virus infections profile negative Normal ceruloplasmin and serum copper levels. GOT 993 IU/L, GPT 1312 IU/L, GGT 209 IU/L
Londoño et al. [24]	Autoimmune hepatitis	Moderna mRNA-1273 COVID-19	After 1 dose	Total bilirubin 2.3 mg/dL (peak of 8.5 mg/dL)

			Case 5: Few hours after 1 dose	Case 5: No autoantibodies
			Case 6: 14 days after 2 doses	Case 6: No autoantibodies
			Case 7: 10 days after 1 dose	Case 7: No autoantibodies
			Case 8: 2 weeks after 2 doses	Case 8: White cells count 12,700/ μ L, CRP 1.4 mg/dL,
				Troponin 103 ng/L, CPK 2380 U/L, no autoantibodies

TSH: Thyroid-stimulating hormone; ft4: free thyroxine; TPO: thyroid peroxidase; Tg: Thyroglobulin; TRAB: thyrotropin receptor antibody; CRP: C-Reactive Protein, ESR: erythrocyte sedimentation rate; USG: ultrasonography; INR: international normalized ratio; LDH: lactate dehydrogenase; ANAs: antinuclear antibody; MPO: myeloperoxidase; p-ANCA: perinuclear anti-neutrophil cytoplasmic antibodies; c-ANCA: centrally antineutrophil cytoplasmic antibodies; IAT: indirect antiglobulin test; DAT: direct antiglobulin test; MCV: mean corpuscular volume; IgG: immunoglobulin G; C3: complement C3; RF: rheumatoid factor; CCP: cyclic citrullinated peptide; HLA: human leukocyte antigens; IL-6: interleukin-6; C4: complement C4; dsDNA: double-stranded deoxyribonucleic acid; ENAs: extractable nuclear antigen; ACE: angiotensin-converting enzyme; IgA: immunoglobulin A; IgM: immunoglobulin; MOG: myelin oligodendrocyte glycoprotein; CSF: cerebrospinal fluid; GM1: gangliosidosis-1; GQIb: Ganglioside GQIb; GM2: gangliosidosis-2; MAG: myelin associated glycoprotein; GAD: glutamic acid decarboxylase; GOT: glutamic-oxaloacetic transaminase; GPT: glutamic pyruvic transaminase. GGT: gamma-glutamyl transferase; ALP: alkaline phosphatase; ASMA: anti-smooth muscle antibody; SLA: soluble liver antigen; LKM1: liver kidney microsomal type 1; LC1: liver cytosolic antigen type 1; AMA: antimitochondrial antibodies; U1-snRNP: U1 small nuclear ribonucleoprotein particle; CENP: centromere protein B; Rib-P: ribosomal P protein; PCNA: Proliferating cell nuclear antigen; AMA-M2: Anti-mitochondrial M2 antibody, CPK: creatine phosphokinase.

These studies have found that the S protein may exhibit similarities with neurological, endocrinological, and gastrointestinal proteins. For the latter, it was found that SARS-CoV-2 exhibits homology with the “Hepatitis A virus cellular receptor 2” [59]. However, none of the reported *in silico* studies found homology related to classic pathogenic epitopes already reported in the literature (Table 1).

Epitope spreading, defined as the “development of an immune response to epitopes distinct from, and noncross-reactive with, the disease-causing epitope” [60], may be an alternative explanation for the autoimmune response associated with COVID-19 vaccines.

On the other hand, since vaccines could be a trigger rather than a cause of autoimmunity [61], bystander activation may be another mechanism for autoimmunity following vaccination. This is characterized by “auto-reactive B and T cells that undergo activation in an antigen-independent manner, influencing the development and course of autoimmunity. Activation occurs due to a combination of an inflammatory milieu, co-signaling ligands, and interactions with neighboring cells” [62]. Given the early development of overt autoimmunity following vaccination (Table 1), it is likely that COVID-19 vaccines primed autoreactive T and B cells in susceptible individuals, accelerating the development of overt autoimmunity.

4. Conclusion

The COVID-19 vaccine may induce the development of ADs, including AIH. The liver injury could be secondary to either bystander activation or epitope spreading, rather than molecular mimicry.

However, autoimmunity prior to vaccination cannot be excluded as a risk factor. As a corollary, high-risk profiles and latent autoimmunity should be considered before vaccination.

Declaration of competing interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Acknowledgments

The authors would like to thank all Diana Monsalve for her contributions and fruitful discussions during the preparation of the manuscript.
