### ABSTRACT

**Introduction:** There is limited access to life-saving antenatal ultrasound in rural and low-resource settings largely due to shortages in skilled staff. Studies have shown healthcare practitioners can be upskilled in PoCUS through focused training, offering a viable solution to this deficit. However, standards for training and competency assessment are unclear and regulation surrounding practice is lacking. We aimed to review published literature examining antenatal PoCUS training programs, comparing teaching approaches and study methodologies.

**Methods:** A search of electronic databases EMBASE, MEDLINE and Google Scholar was conducted. Original research articles evaluating antenatal PoCUS training of healthcare professionals worldwide were identified for analysis. Articles with limited detail on the PoCUS training intervention and those describing comprehensive diagnostic training programs were excluded. Evaluations were compared against the Kirkpatrick Evaluation Framework (KEF).

**Results:** Twenty-seven studies were included from an initial search result of 484 articles. There was considerable heterogeneity between the PoCUS training programs described. Course duration ranged from 3 hours to 2 years, with 11 of the 27 studies delivering obstetric-exclusive content. 44% trained multidisciplinary groups of health professionals. Long-term follow-up training and skills assessments were lacking in over half of the reviewed studies. Study quality and reporting detail varied, but overall beneficial outcomes were reported with 3/4s of the studies reaching upper KEF levels 3 and 4.

**Conclusion:** PoCUS performed by upskilled healthcare professionals offers an attractive solution to the problem of inequitable access to antenatal ultrasound. A review of available literature highlighted a paucity of comparable high-quality studies needed to establish a stronger evidence base for antenatal PoCUS, and a need to standardise training and competency assessment. This review may inform educators, researchers and policy-makers on existing training formats and methodologies to assist in establishing best practice antenatal PoCUS training methods for safe service delivery by remote healthcare professionals.

### ARTICLE HISTORY

Received 11 July 2021

Accepted 9 February 2022

### KEYWORDS-

Medical education; training; antenatal; obstetrics; Point-of-Care Ultrasound (PoCUS); continuing professional development; low-resource setting; rural; remote

## Introduction

Antenatal ultrasound is the primary imaging modality in pregnancy [1,2], routinely used to estimate due dates, monitor fetal growth and well-being, detect anomalies, and guide specialist referral [3,4]. It can also facilitate the early detection of life-threatening complications such as ectopic pregnancy, fetal mal-presentation, multiple pregnancies, placenta praevia and placental abruption [5–8]. The International Society of Ultrasound in Obstetrics and Gynaecology (ISUOG) have published guidelines recommending women receive two antenatal US examinations during a normal low-risk pregnancy [9]. However, studies into service accessibility in rural, remote and low-resource settings around the world indicate women are not receiving this care [10–12]. The WHO estimates most maternal deaths are

preventable, with over 90% occurring in low-resource settings. Approximately 86% of estimated global maternal deaths in 2017 were attributed to the developing nations of sub-Saharan Africa and Southern Asia [13]. The majority of neonatal mortality also occurred in these regions [14]. A 2015 survey of healthcare providers in South America, Africa and Asia reported the primary reason for not making ultrasound available to pregnant women was a lack of suitable education [15]. Skill shortages are also evident in developed nations like the USA, Canada and Australia, where many remote medical centres have no onsite sonographer and rely on visiting professionals available as infrequently as one day per month [10,16]. The recent COVID-19 pandemic has increased uncertainties in travel and logistics, impacting locum staffing in rural areas and highlighting the importance of trained remote healthcare workers.

Accurate estimation of due dates and early detection of potentially life-threatening complications are crucial for remotely located women, who may need days of travel to access specialist obstetric care [7,10,17]. It is in these low-resource settings that antenatal Point-of-Care ultrasound (PoCUS) can offer substantial benefits.

Modern portable ultrasound machines capable of producing high-quality images are affordable and have helped establish PoCUS in many medical fields [1,3]. Performed and interpreted at the bedside by the healthcare provider, PoCUS allows for focused studies to assist procedures or direct care and referral [18]. As a highly skilled, operator-dependent modality, PoCUS requires appropriate and ongoing training of experienced healthcare professionals [3]. It takes years of study and training to produce qualified sonographers, and once trained it is challenging to entice these professionals to relocate and remain in rural locations [16,19,20]. There is growing evidence indicating PoCUS training programs can effectively teach the skills necessary to allow for task-shifting of focussed ultrasound examinations from sonographers to doctors, nurses and midwives [21–26]. Ultrasound training is being increasingly incorporated into undergraduate medical curricula and on the job training [26–28], but it is less well established in non-physician (nursing and midwifery) programs [29,30]. In most developing countries and low-resource settings, antenatal care is provided primarily by midwives and nursing staff, which presents an opportunity to task-shift and upskill these essential workers [21–26].

**Table 1** lists general PoCUS workshop requirements and methods for assessing competency [31–33]. The WHO recommends a standardised curriculum and competency assessment be adopted by all countries for antenatal PoCUS training [5]. However, training guidelines and standards to ensure a minimum level of competency for safe practice vary between countries, with PoCUS remaining largely unregulated globally [34–36]. In many countries, health practitioners may perform PoCUS with little or no training, and without formal accreditation, leading authorities to call for reform and regulation of its use [16,37]. Ultrasound performed by untrained clinicians may represent a higher risk of misdiagnoses. Overlooked health conditions may lead to delayed diagnoses and treatment ('false negatives'), while misinterpretations and incidental findings ('false positives') can cause considerable patient anxiety and unnecessary follow-up investigations, increasing the economic burden on the healthcare system [38–40].

Endorsement for outreach training programs have been provided by the Australasian Society for Ultrasound in Medicine (ASUM), ISUOG, World

Federation for Ultrasound in Medicine and Biology and RAD-AID, indicating a global effort to address the skill shortage [35]. This literature review examines the training and evaluation methods being employed to teach antenatal PoCUS to medical and allied health professionals.

## Methods

This review investigated international literature on antenatal PoCUS education from 2000 to January 2021, focusing on publications that evaluate the efficacy of training models. It has adopted the 'Preferred Reporting Items for Systematic Reviews and Meta-analysis' (PRISMA) guidelines and was formerly registered with the international prospective register of systematic reviews (PROSPERO), registration number CRD42021230267.

A team of three researchers from the University of South Australia with experience in research, tertiary education and clinical practice (including ultrasound and PoCUS training in low-resource settings) conducted the review and reached consensus on the eligibility criteria, search strategy and terms, final article inclusion, data extraction and quality assessment.

## Search strategy

A systematic search of electronic databases EMBASE and MEDLINE was conducted through OVID for original research literature, performed on the 7<sup>th</sup> of January 2021. An experienced librarian was consulted to assist in the design of search terms and strings, which were then reviewed by all members of the research team. The search was limited to 'Human' and 'English' language only. No restrictions were set regarding the publication year. Search terms used for both databases were grouped into main four areas and combined using terms synonymous with pregnancy, ultrasound, point-of-care, and training. A grey literature search was conducted through Google Scholar (5 pages, 50 results) using the key search terms (pregnancy/antenatal, point-of-care ultrasound/ultrasound, and training/education). Connected papers (<https://www.connectedpapers.com/>) was searched to canvas for additional relevant articles (see **Appendix Table A1: Search strategy**).

## Eligibility criteria

For inclusion, an original research study must have described and evaluated an ultrasound training program intended for point-of-care or bedside application on antenatal patients. Articles involving PoCUS obstetric training as part of a broader training curriculum were eligible. All medical and allied health

**Table 1.** General PoCUS workshop requirements and methods for assessing competence.

General workshop requirements defined by *ASUM[31,32]	Methods for assessing competency in PoCUS[33]
Faculty- must include a medical specialist with appropriate and extensive clinical experience/qualifications. Instructors must have significant practical experience in the application being taught. Registered sonographers can assist with teaching skills.	Technical competency assessment- Probe selection, image mode selection (e.g., cardiac, obstetric), proper image orientation, probe positioning, depth, gain, centering of target structure, demonstrates advanced functions (M-mode, Doppler, image capture), troubleshooting.
Teaching (including practical) hours should at least meet those published in credentialing syllabus for the application taught.	Knowledge assessment- Course entry assessment following pre-reading Pre and post course assessment Multiple-choice questions Written answer
Provision of course syllabus, learning materials, recommended texts and other references. Instructor to candidate ratio 1:5. Machine to candidate ratio 1:5. Appropriate models and patients. Setting to accommodate lectures and practical scanning sessions. Pre- and post-course tests.	Objective Structured Clinical Examination (OSCE) / Practical examination. Standardised checklists for evaluating technical skill. Skill assessment on simulator, model, or standardised patient. Review of images obtained on real patients. Real-time assessment of scanning actual patients and clinical decision making. Longitudinal patient evaluation and periodic review to assess image quality and accuracy of PoCUS interpretation.
Evidence of attendance including course hours.	Self-assessment- Knowledge/skill Perceptions/attitudes Change in work behaviour/scanning frequency

\*ASUM- Australasian Society for Ultrasound in Medicine.

specialties were included as the training participant population, and pre-graduate students from all health disciplines. No restrictions were placed on study/training setting.

Studies evaluating advanced training (complex and interventional scanning) or formal diagnostic ultrasound programs leading to qualification as a sonographer were excluded. Articles with limited descriptions of the training program provided were excluded, as were conference abstracts/reviews, editorials, commentaries and letters (see **Table 2: Eligibility criteria**).

The database search was performed by the primary author. Duplicates were removed prior to the initial title and abstract screening conducted independently by two reviewers, who then performed full-text reviews. Non-consensus at both initial title/abstract screening and later full-text screening was decided by a third independent reviewer. The citations of all identified articles included in the review were searched, with title/abstract then full-text screening performed by two independent reviewers.

### Data extraction and synthesis

All three reviewers discussed themes and agreed on data points to be extracted, and reviewed these predetermined categories in a Microsoft Excel spreadsheet prior to data extraction. Data was extracted to the spreadsheet and collated by the primary author and examined by a second reviewer. Meta-analysis was not possible due to the heterogeneous teaching and assessment methodologies used, thus an integrative approach to data synthesis was employed. Emerging themes were discussed amongst all three

reviewers and a narrative response was composed. Comprehensive tables summarising the reviewed studies' training and evaluation methods, and key investigated outcomes are included to facilitate comparison.

### Quality assessment

A modified Medical Education Research Quality Index (MERSQI) tool (see **Appendix Table A2**) was used to assess the quality of the included articles. The MERSQI is a validated assessment instrument used in medical education research to measure the quality of experimental, quasi-experimental and observational studies [41,42]. The tool was modified to include two categories: 1) 'Number of trainees' (score of 0.5 to 1.5), and 2) 'Follow-up of training' (score of 0 to 3). These domains were considered valuable to this review given the variation of recruited participant numbers between studies (impacting study power), and the importance of follow-up training, assessment and ongoing support of trainees for learning PoCUS and ensuring safe practice. The percentage response rate was omitted as this measure was not applicable to the vast majority of the studies. Each domain was scored out of 3. The primary author performed the quality assessment, grading all articles within a potential score range of 5 to 21. A risk of bias assessment was also conducted relating to five key areas of educational development: Underpinning bias, Resource bias, Setting bias, Content bias, Educational/Development bias (see **Appendix Table A3: Risk of bias assessment tool**). However, assessment of quality and risk of bias did not restrict article

**Table 2.** Eligibility criteria.

	Include	Exclude	Rationale for exclusion
Population	Health care clinicians/practitioners- Nurses, Midwives, Doctors, Allied health workers, students from all health disciplines.	Sonographers Non-health professionals.	Sonographers and trainee sonographers possess more advanced imaging skills and are not within the scope of this review. Focus on training of populations with minimum basic healthcare training/experience/qualification. It is not advisable for non-healthcare professionals without training to perform PoCUS on patients/people.
Intervention/ Exposure	Antenatal Point-of-Care ultrasound (PoCUS) training including broader courses teaching scanning of multiple organ systems.	PoCUS training with no antenatal specific content (e.g., critical care- FAST, Abdominal, cardiac, lung, vascular). Advanced training (complex and interventional scanning) or full diagnostic ultrasound training leading to registration and qualification (sonographer training).	Non-antenatal PoCUS training is beyond the scope of this review. This review is focused on basic PoCUS training of health professionals. Advanced training such as those requiring lengthy courses, long-term supervision and formal accreditation/registration are beyond the scope of this review.
Outcome	Efficacy of training.Types of evidence/ evaluation measures: Training course evaluation/Trainee satisfaction, testing of knowledge and practical skills (OSCE), Image quality review, diagnosis review, Confidence measures, Scanning frequency, Maternal/fetal outcomes.	Articles with limited description or reporting of the training intervention (training delivered), training assessment (evaluation measures) and outcome.	Inadequate methodological detail inhibits quality assessment and comparison between studies.
Study type	Original research. Studies involving antenatal PoCUS training evaluation- Cohort studies, cross-sectional studies, case control studies, observational studies, qualitative studies, case reports, clinical and randomized control trials. English language. Clinical/Human studies.	Review articles, Conference presentations/ Abstracts, Letters, Editorials, Commentaries. Articles with insufficient detail of described training interventions (training delivered), training assessment (evaluation measures) and outcome. Non-English articles. Animal studies.	Only original research articles were included for review. Conference presentations and abstracts (not full length articles) provide insufficient detail and peer-review scrutiny.

inclusion in this review's final synthesis, ensuring the inclusion of a broad cross-section of literature representative of the range of study quality and methodologies in published circulation.

Each study reviewed was compared against The Kirkpatrick Evaluation Framework (KEF), a validated four level model designed to evaluate and classify training and development programs [43,44]. The four levels described (Level 1- Reaction; Level 2- Learning; Level 3- Behaviour; Level 4- Results) by the Kirkpatrick model represent a continuum of complexity and value in evaluation measures. Level 4, representing the highest evaluation measure (healthcare or patient-related outcomes), assesses impact and aligns with the MERSQI 'Outcomes' domain.

## Results

Twenty-seven studies were included, from an initial 484 articles retrieved in the OVID database search during the identification stage (see **Figure 1: PRISMA framework**). Of the 27 articles, 16 were identified through EMBASE and MEDLINE, with a further 11 obtained through citation searches. Google Scholar and Connected papers searches yield no additional eligible articles.

The identified studies spanned two decades; the oldest study published in the year 2000. Three-

quarters were published after 2014 reflecting the growing interest in PoCUS research. Most were single arm interventional studies using convenience samples of health professionals and patients. Four of the studies were conducted by the same research team, Shah et al. [45–48]. Twenty studies were conducted in developing countries, of which only five were conducted in urban settings. Seven studies included developed countries (five in the USA, all urban areas with one intended for rural deployment; one in Australia and one in Denmark). Two of these studies used training sites in both developed and developing countries; one [49] employed a clustered randomised control trial design that was carried out over five clinical sites located in Africa, Asia and America, and the other [50] compared six training sites and formats conducted in rural and urban settings in Australia, Timor Leste and Indonesia. Key outcomes investigated and the main findings of the studies are summarised in **Table 3**.

## Training methods and delivery

A summary of the included studies' teaching methods, including duration and location, trainee and instructor demographics, curriculum and practical skills taught, and follow-up training/support, is provided in **Appendix Table A4: Training methods and delivery**.

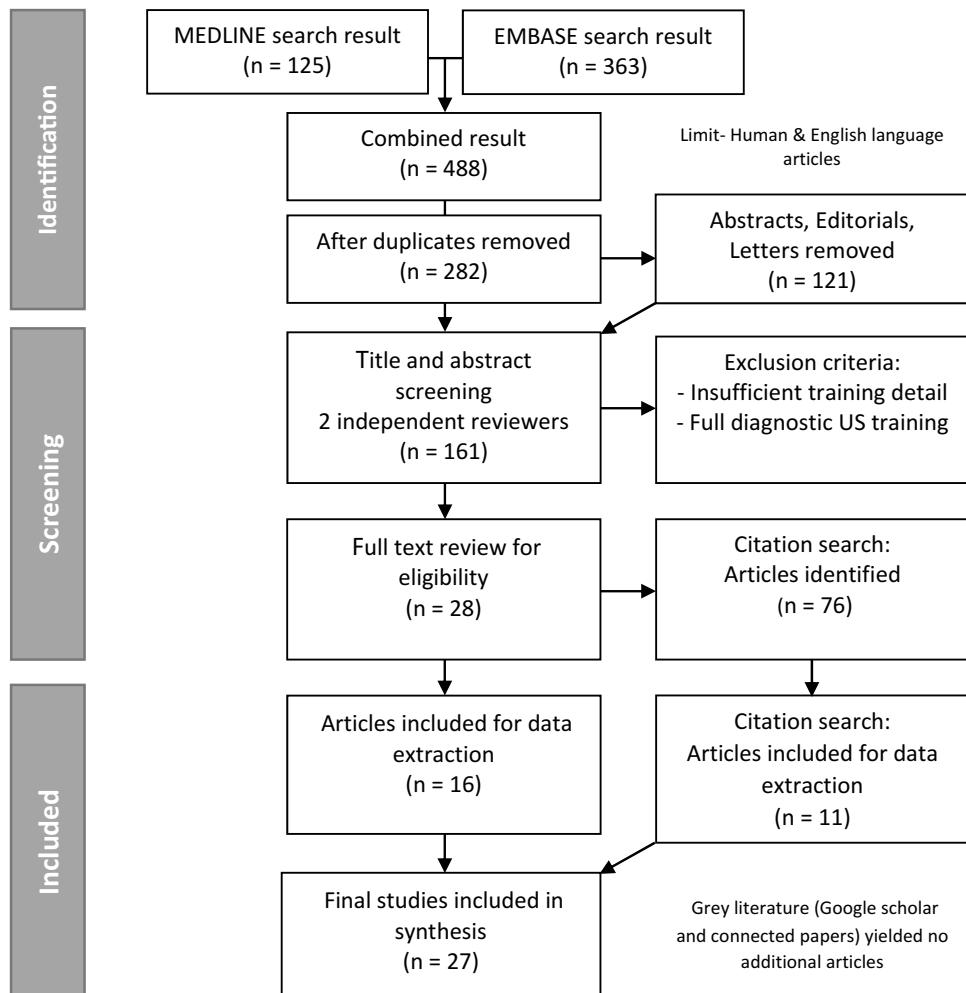

Figure 1. PRISMA framework – Search results.

## Curricula

Course duration ranged from 3 hours to 2 years. Obstetric-exclusive curricula were delivered in 11 of the 27 studies (see Figure 2a). Of the studies that covered multiple-organ systems, several delivered their content in as few as 1–2 days [21,22,51,52], with either refresher sessions or additional online learning modules provided to support the intensive practical training. When designing intensive courses with limited delivery time, other resources to supplement face-to-face training, such as digital and written learning modules/resources, and online/distance teaching and feedback are important. Many of the studies employed these supportive measures (see Appendix Table A4). Maintaining a focussed curriculum for specific predefined clinical indications and remote technical assistance was recommended [51].

The course topics and practical skills taught by each study are listed in Table A4 of the Appendix; these ranged from basic assessments like fetal lie/presentation to more complex fetal biometry, heart assessment and the detection of anomalies such as ventriculomegaly, anencephaly, hydronephrosis, and spina bifida. A training needs assessment was conducted by five of the

studies [24,26,46,47,53] which informed the choice of ultrasound applications that were most relevant for program inclusion. Specific skills were taught if relevant to endemic needs; for example, three studies [51,54,55] conducted in Tuberculosis prevalent regions included ultrasound assessment of HIV/Tuberculosis (FASH) in their multisystem curriculum.

Over two-thirds of the studies detailed ultrasound physics and instrumentation in their curriculum, and four specifically mentioned ‘safety’ [30,45,49,56], consistent with the WHO’s recommendations that trainees are able to monitor mechanical and thermal indices on equipment and understand safety concepts underpinning ultrasound exposure of the patient and fetus [57]. Trainees should understand the limitations of their focussed training and seek assistance with image interpretation and patient management decisions from an experienced sonographer and/or clinician where necessary. Appropriate documentation of the PoCUS exams findings and patient referral is also important. Three of the studies listed ‘documentation’ in their curriculum [29,30,58], one specifically including ‘liability and risk reduction strategies’ [29].

**Table 3. Key outcomes investigated and findings.**

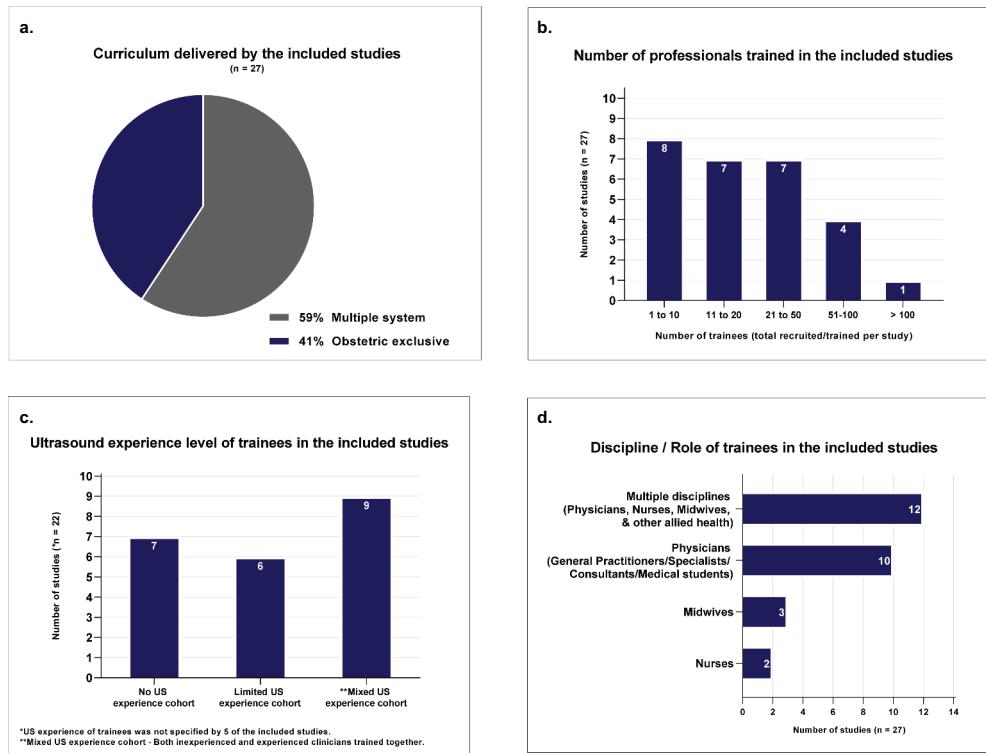

First author Year Published	Key outcomes investigated	Main Finding in relation to antenatal PoCUS
Adler [66] 2008	Frequency & application of PoCUS following training.	Pregnancy-related exams accounted for 24.1% of total. US is a feasible & sustainable imaging modality in a very low-resource setting (refugee camp).
Baltarowich [61] 2009	Trainee knowledge acquisition & retention – written test scores compared at 3 points in time over 6 months.	Mean test scores increased significantly- 58.4% at entry to 76.8% at end-of-program. Nine of the 12 physicians were selected to establish affiliated US training programs in their own country.
Bell [22] 2016	Written & practical test scores; before & after refresher training. Frequency & application of PoCUS following training.	Strong correlation between knowledge & practical skill scores. Increase proportion passing both knowledge & practical tests at follow-up, compared to initial session. 90% trainees completing more than 1 session maintained or improved scores. Follow-up survey- 2/3 to 3/4 reported using PoCUS over 20 times in previous 3 months. Obstetrical exams were most commonly performed and had the greatest impact on patient management.
Dalmacion [25] 2018	Trainee to instructor image comparison.	95% agreement between the trainee & instructor US. Estimated 6.3% of maternal deaths & 14.6% of neonatal deaths possibly averted by the early US screening.
Dornhofer [54] 2020	Estimate of maternal/fetal deaths averted. Pre- & post-course written & practical examination scores (compare physicians, nurses, & midwives). Post-course survey of trainee scanning confidence.	No participants passed (>65%) the pre-course examination. 43 (72%) passed the course & 12 (28%) failed. Written exam pass rate- Fifteen (79%) physicians, 11 (82%) nurses, & 13 (68%) midwives. Average practical examination score was 83% ( $SD = 16.2\%$ ) for physicians, 82% ( $SD = 11.4\%$ ) for nurses, and 71% ( $SD = 15.2\%$ ) for midwives. Physicians performed best on pre- & post course written exams, followed by nurses & then midwives. Nurses scores improved most, followed by physicians & midwives. The average practical score for physicians was significantly greater than midwives ( $P = .038$ ). The average practical score for nurses was significantly greater than for midwives ( $P = .049$ ). All trainees reported increased post course comfort levels performing PoCUS. 100% sensitivity & 98% specificity for expert reviewed OB images (94% & 98% overall).
Henwood [53] 2017	Expert review of trainee images. PoCUS application. PoCUS impact on patient management.	Trainees most frequently used US for abdominal & OB applications. 81.3% of patients had at least one clinical decision changed because of a PoCUS.
Kimberly [62] 2010	Practical assessment (OSCE) of skills & sustainability over time (2 & 6 months). Expert review of trainee images. Frequency & application of PoCUS following training. PoCUS impact on clinical decision making/patient management.	Paired OSCE scores- slight overall improvement over time. Trainees most competent at identifying number of gestations (100%), & fetal presentation (96%). calculating FHR (48%) was more challenging. Scan review- FHR interpretation 96% agreement, placental location 91% agreement, BPD 70% agreement. Mean of 21 scans performed per trainee over 6 months. 2 <sup>nd</sup> & 3 <sup>rd</sup> trimester most common. Main indications recorded- Size to date discrepancy (44%) & determining fetal position (39%). US prompted change in clinical decision-making in 17% of cases. At 1 year follow-up- trainees average 10 PoCUS per week. 85% reported helping colleagues use US. 46% reported significant time constraints as main limitation. Average expert rating of trainee images-6.5/4.10 in first 6 weeks & 7.1/7.10 in last 6 weeks. 52% (CI- 44-61%) of patients had a new diagnosis after PoCUS. A new diagnosis lead to change in management in 48% (CI 40-57%) of patients.
Kolbe [26] 2015	Expert review of trainee images. PoCUS application/indication. PoCUS impact on clinical decision making/Patient management.	Mean confidence score pre-test to post-test improved from 23.3 ( $\pm 10.2$ ) to 37.8 ( $\pm 6.7$ ). Before & after training, trainees overwhelmingly agreed US would improve their practice, make them a better surgical resident, & improve their practice in LRs. All agreed the US course helped them improve their PoCUS knowledge & skills.
Kotagal [56] 2015	Change in self-assessment scores regarding attitudes, confidence & assessment of the value of US before & after training intervention.	All 4 trainees credentialled to perform US clinically within one month. Portfolios & evaluation rubric offered a consistent, systematic means to demonstrate the acquisition of skills for clinical practice. And were a more effective & practical method of demonstrating trainee competence & supporting credentialing over a physician's subjective impression of trainees' abilities.
Lathrop [58] 2011	Learner portfolio & hands-on workshop for US credentialing & training. Learner feedback meeting.	Average pre-course exam score was 35.2% (2.4% pass rate). The average post-course exam score was 82.0% (92.7% pass rate). Average practical score on completion of the course was 83.2% ( $SD = 0.145$ ) with 82.9% of the class passing (pass mark above 75.0%). Post-course survey- overall increased level of comfort performing all scans. Cardiac followed by OB US were anticipated to be most frequent indication.
Lee [55] 2017	Pre & post course trainee knowledge assessment. Post training practical skills assessment and course evaluation survey (scanning confidence & intent-to-use US).	Expert to trainee agreement for intrauterine pregnancy-100%. GA- 93%. Low-to-moderate complexity PoCUS exams performed by GPs with sufficient prior training have a very high level of inter-rater agreement when compared to exams conducted by radiologists & gynaecologists.
Lindgaard [52] 2017	Expert review of trainee images.	(Continued)

**Table 3.** (Continued).

First author Year Published	Key outcomes investigated	Main Finding in relation to antenatal PoCUS
Mandavia [67] 2000	Trainee knowledge acquisition & retention- written test scores before & after training & at 10 month follow-up (stratified by discipline & US experience). Expert review of trainee images. Frequency & application of PoCUS.	The mean pre-test score was 65%, mean post-test score 84%. No decline after 10 months. Pre-test variation based on US experience not evident after training. Image review- overall sensitivity of 92.4% & specificity of 96.1% (95% CI = 94% to 98%). OB only exams were 94% sensitive & 100% specific. Frequency of scanning varied widely (9–152), averaging 62 exams over 10 months. Biliary, renal and trauma were the most frequent indications for scanning. 36/41 trainees passed the practical test on first attempt at the end of 2 week course & 40/41 passed at the end of 12 week pilot period. Mean practical skills score increased- 78% on the first test to 92% on the fourth test. Of the 3801 US exams (32,480 images), 94.8% were rated as satisfactory by expert review. Concordance between trainee & reviewer US diagnosis was 99.4%. High-risk pregnancies were identified by the trainees in 6.7% (255/3801) of exams.
Nathan [49] 2017	Written & practical skills assessment. Expert review of trainee images for errors in scanning parameters & diagnosis, using predetermined criteria. Site, patient & trainee demographics.	The most common studies were TA OB exams (45.5%) and abdomen/pelvis (26.6%). US scanning peaked after teaching sessions then gradually decreased over months. Highest recorded scans were after the final teaching session. Disagreement in findings in 4.3% of the images reviewed (none affected clinical management) & 6.5% with inadequate image quality to interpret. PoCUS changed patient diagnosis in 34% (24% for OB patients) & clinical management in 30% (20% for OB patients). In the scans that changed the diagnosis, 78% led to changed clinical management.
Rominger [24] 2018	Frequency & application of PoCUS following training. Expert review of trainee images. Impact on patient management & diagnosis.	Of 25 trainees, 22 passed (average score 89.4%) the OSCCE on first attempt. Image quality improved with time; the final error rate at week 8 was less than 5%. Confidence levels increased- pre-course 1 point average to over 6 points post-course for all measures (maximum 7). Key informant interviews- indicated a desire for more hands-on training, longer training duration & challenges in balancing clinical duties with ability to attend training sessions. For previously untrained trainees, pre- & post-test knowledge scores improved from 65.7% ( $SD = 20.8$ ) to 90% ( $SD = 8.2$ ) ( $p < 0.0007$ ). Self-confidence improved significantly for identification of FHR, fetal lie, & EGA. Average times for completion of critical skills: cardiac activity (95), FHR (68.6s), fetal lie (28.1s), & EGA (158.1 sec). EGA estimates averaged 28w0d (25w0d-30w0d) for the model's true GA of 27w0d.
Shah [45] 2020	Practical OSCCE assessment & accuracy of images & measures over time. Blinded expert image review for QA & inter-rater reliability of reviewers. Confidence levels pre-post training & at 3 months follow up. Post course evaluation/training perception interviews. Pre- & post-course knowledge & confidence assessment. Time & accuracy of scanning.	OB scanning was the most frequently used application followed by abdominal. Evaluation of GA, fetal head position & placental positioning were the most common findings. Local staff performed 245 US scans in the 11 weeks after the departure of the US instructor. Expert to trainee agreement on scan review of 96%. US changed patient management in 43% of patients.
Shah [47] 2009	Reporting impact of previously published training program (Shah 2008) Patient demographics & US application. Blinded expert image review of trainee images for quality & accuracy. PoCUS directed change of patient management. Initial US needs assessment, training curriculum development & implementation. Staff survey of prior US experience & hospital records review.	10 of 15 physicians completed the training. Needs assessment-all 15 trainees rated OBs most important application. Focus group discussion- barriers to US services included distance, time & cost for transfers, lack of monitoring during transfers & US charges. Dissatisfaction expressed US report quality & inability to view images with written reports. Course evaluations were extremely positive. Trainees expressed enthusiasm to develop basic US competencies & recognised the applicability of new skills to clinical practice. Hands-on sessions were universally appreciated- requests for additional or longer sessions, more pregnant volunteers & reducing group size (trainee to faculty ratios). Trainees reported teaching varied types of trainees together as "innovative & helpful" but also perceived to be challenging.
Shah-Battista [29] 2015	Pre & Post course knowledge assessment. Post course evaluation. Other project evaluations/outcomes ongoing & not reported including: pre- & post-online module knowledge of OB US, interprofessional competencies, & post-training knowledge following seminar & practical.	Main applications for PoCUS- cardiac exams followed by 2nd & 3rd trimester OB exams. Over 75% reported use of PoCUS in clinical diagnoses & 50% in determining treatment. 50% reported very frequently or often using US to teach within their clinics. Largest perceived barriers- lack of clinical educators US knowledge, lack of time, equipment security, difficulty accessing the internet & equipment problems.
Shokoohi [51] 2019	Trainee demographics including US experience. Frequency & application of PoCUS following training. Teaching of other staff/students. Challenges/barriers to integrating US into patient care.	Of 22,639 ED patients evaluated, PoCUS examinations were performed on 1,886 patients. OB scans (9.3%) were 3rd most common scan after FAST (53.3%) & Echo (16.4%). PoCUS studies were performed more frequently than radiology department-performed studies. Positive findings were documented in 46% of all PoCUS exams.
Stoltz [30] 2015	Frequency & application of PoCUS over duration of training course. Patient/scan outcome.	Expert review of trainee images- 100% sensitivity & specificity for identifying gestational number, 90% sensitivity & 96% specificity for fetal presentation. Trainee PoCUS altered clinical diagnosis in up to 12% of clinical encounters.
Swanson [85] 2014	Expert review of trainee images. Diagnostic outcome following PoCUS.	(Continued)

**Table 3. (Continued).**

First author Year Published	Key outcomes investigated	Main Finding in relation to antenatal PoCUS
Vinayak [63] 2017	Post e-module assessment (pre hands on) & post course written assessment. Expert review of trainee images for quality & accuracy of interpretation. Patient outcome following PoCUS. Patient experience.	E-module knowledge reported useful. All trainees passed the written post-course exit exam on 1st attempt. Reporting accuracy of trainees' scans was 99.3%. Reduced AFI missed on 2 patients scans. Time to complete scan halved after completing 30 scans. All 246 patients felt the process was safe, convenient & reassuring, had a better antenatal visit experience & increased confidence in care delivery. More spouses attended than for routine antenatal visits.
Vyas [70] 2018	Post-training OSCE practical assessment. Image quality review & trainee identification of pathology. Patient outcome.	Trainees were able to correctly identify fetal presentation, fetal number, & placental position in all enrolled patients. BPD correctly assessed in 95.3% & HC 90%. GA had a mean difference from expert sonographers of 1.5 days (BPD) & 0.26 days (HC). All 4 patients with abnormal findings were expert confirmed.
Wanjiku [21] 2018	Pre-training knowledge assessment. OSCE practical assessment with image quality scores. Frequency & application of PoCUS following training.	OB images received the highest mean image quality score (compare to FAST, thoracic & echocardiography). Image quality scores increased with an increase in training sessions and decreased with increasing time since prior training. OB US were most frequently performed. Frequency of scanning positively correlated with written & image quality test scores.
Westerway [50] 2019	Trainee knowledge acquisition & retention – written & practical tests before & after training & at 6/11 month follow-up. Comparison of PoCUS courses (rural/urban sites, duration, student numbers). Course evaluation- satisfaction, engagement, understanding & relevance of learning. Scanning on return to work.	Practical assessment at 6/11 months- minor prompting for image optimisation (depth, gain & imaging plane for fetal biometry) for all but 4 trainees who had peer support at work following training. All (55) trainees achieved the course objectives, regardless of format. Course evaluation- all trainees stated understanding what was taught & relevance to their clinical work. All trainees continued scanning on return to work.

**Figure 2.** Of the included studies in the review a. Curriculum delivered (Multiple organ systems taught or Obstetrics and gynaecology only); b. Number of professionals trained (total recruited and trained per study); c. Ultrasound experience of trainees prior to undertaking the training; d. Discipline/role of the trainees (Multidiscipline/Physicians/Nurses/Midwives).

### Trainees' previous ultrasound experience

Participant trainee numbers in any single study ranged from 3 to 162, with a total of 903 trainees across all included studies. Over half of the studies trained fewer than 20 trainees, limiting study power (see Figure 2b). Of the studies that reported trainees' prior ultrasound experience, nine trained participants with mixed ultrasound experience, six enrolled trainees with limited but similar ultrasound exposure and seven restricted eligibility to trainees with no prior ultrasound training or experience (see Figure 2c). Delivering a program to suit trainees with varied ultrasound education and proficiency was an acknowledged challenge [22,51]. Shokoohi et al. [51] raised concerns that more experienced trainees may not have received the same benefit from their curriculum, particularly in the introductory session. Grouping trainees and designing specific curricula and objectives catered to each groups' experience and skill level could mitigate this problem.

### Multidisciplinary training groups

The future of healthcare and its education is moving towards a more cooperative interdisciplinary culture [59], demonstrated in the multidisciplinary participant groups trained together in almost half of the reviewed studies. Ten (33%) studies exclusively trained medical physicians and only 5 (19%) were

dedicated to nurses and midwives (see Figure 2d). Several authors [29,50] described unique challenges to interprofessional teaching, where individual needs and preferences can vary significantly between trainees. This scenario, however, provides the opportunity to use trainees' unique experiences and individual strengths to enhance course design and foster collaborative practice. Shaw-Battista et.al [29]. reported enhanced inter-professional collaboration as a benefit of their multidisciplinary PoCUS training initiative, stating it fostered better communication, coordination of care and understanding of other professionals overlapping and unique scopes of practice. Providing clear objectives, varying curricula in breakout groups tailored to participant's experience level, and the opportunity for peer-led teaching in mixed skills/experience groups would benefit a multidisciplinary PoCUS training cohort.

### Instructors' experience

Instructor-to-trainee ratios were reported in over half of the studies, mostly for practical training sessions, and ranged from 1:1 to 1:6; guidelines have recommended a maximum ratio of 1:5 [32,60]. The instructors' experience ranged from second year medical students (aimed at providing low-cost outreach training in developing countries [54,55]) to trained

sonographers and medical specialists. Some courses benefited from a multidisciplinary teaching team with specialised content delivered by experts in their field (cardiac, paediatric and obstetric specialists). Several articles included principles of teaching in their curriculum [45,61], and reported scenarios where trainees went on to teach ultrasound to colleagues on return to work [51,61,62]. Training the trainer initiatives, where trainees are taught teaching methods to pass on learning to colleagues, is a useful and potentially cost-saving option in settings with limited resources and access to training. Care should be taken using this teaching model with PoCUS courses of short duration, given the complexities of learning ultrasound and the often unsupervised work environments trainees return to. Instructor qualifications and teaching ratios are provided in **Appendix Table A4**.

### **Ethical considerations**

Few papers mentioned the ethics surrounding the use of pregnant patients for ultrasound training purposes. Ideally, practical training would utilise both simulated and real-life patients with strictly limited times placed on scanning pregnant volunteers and a heavier reliance on phantom models and virtual/simulation technologies in early training [50,63]. In most studies, only healthy models were used during training, which precludes the demonstration of pathology [29,55]. Simulation can be beneficial in this respect and offers the advantage of learning in a safe, patient-free environment. They have a particular utility in obstetric ultrasound training, but the cost of implementing high-fidelity simulated systems would be prohibitive in the majority of settings reviewed [64,65]. Westerway [50] reported using commercial and handmade phantoms and Vinayak et al. [63] used 'scanning phantoms' in the initial week of training, but no high-fidelity simulation systems were used in any of the reviewed studies. Shaw-Battista et al. [29] discussed the ethics of using pregnant models, stating their intention to introduce equipment to simulate first-trimester ultrasound in their next course iteration. This would reduce reliance on pregnant volunteers and provide the opportunity to scan simulated first trimester pregnancies, commonly lacking in training courses due to the early gestation of the fetus and risk of identifying an unexpected abnormality in pregnant volunteers who are yet to receive formal scanning.

### **Follow-up training and support**

Follow-up training is beneficial to reinforce learning and provides the opportunity to assess knowledge retention, which is important for continued safe practice. Follow-up training sessions, in either face-

to-face or online format, were offered by half the studies, with periods varying from 3 months to 2 years. **Appendix Table A4** summarises the follow-up training and support provided by the reviewed studies. Of those who did not report/provide additional follow-up training sessions, five offered assistance through personal telecommunications feedback and image review. Telemedicine was investigated by Kolbe et al. [26] who provided remote real-time scanning and image review. Vinayak et al. [63] used an asynchronous method, where trainee images and interim report was sent for specialist review while the patient waited. Other studies used telecommunications via email and various messaging platforms to remotely assist trainees, provide feedback and review images, but only Kolbe et al. [26] used remote real-time scanning supervision.

### **Training evaluation and assessment methods**

The approach and method used to evaluate the courses and trainees varied widely across studies. A summary of the evaluation methods reported including knowledge and practical assessment, expert image review, frequency and application of scanning, patient outcomes and trainee feedback/survey is provided in **Table 4: Trainee & course evaluation**.

Fourteen studies performed knowledge assessment of the trainees. Nine of these conducted pre- and post-training tests, and of these, five administered identical exams before and after training. Utilising the same exam allows for a quantifiable measure of trainee improvement but can introduce bias. This risk may be mitigated by randomising question order, not informing trainees the test would be re-administered or discussing test results. Trainees from five studies were required to pass a written test following online self-directed learning before proceeding to practical training. Pre-course learning and testing saves face-to-face time for hands-on learning and can ensure trainees have similar base knowledge on course entry. Six studies reported performing follow-up (knowledge retention) assessment in addition to any immediate post-course testing. Practical assessments or Objective Structured Clinical Examinations (OSCE) were conducted in 16 of the studies, of which half performed consecutive testing allowing for improvement measures. Overall, half the studies performed expert image review (remotely or during training) for quality assurance and to assess competence, and for some, to guide feedback and the necessity for refresher training. This is a useful competence measure where direct supervision is not possible, as it may be performed asynchronously and remotely. Written or practical assessments were not described by seven of the studies. Of these, expert image review

was performed by four studies as an indirect evaluation method.

Almost half the studies investigated patient outcomes, several going further to ascertain if PoCUS changed the patient diagnosis and if this impacted their management/treatment. The clinical application was evaluated in nine studies, and in some cases, the frequency of scanning following training was used as an evaluation measure [21,24,30,51,53,62,66,67]. Other measures useful for quality control and course improvement are post-course evaluation surveys, conducted by seven [21,29,45,50,51,54,55] of the reviewed studies, and self-reported post-course scanning confidence that was evaluated by three [45,54,56]. Several studies [48,63] used ‘time to complete scans’ as an evaluation measure. In Vinayak et al. [63] scan times halved after 30 completed examinations with consistent image quality. While not the best measure of competence, speed is an important consideration in time poor, resource-limited settings where extensive scanning times could be prohibitive to PoCUS examination during antenatal consultation. Shah’s et al. [48] study demonstrated that an entire focussed ultrasound assessment (fetal heart rate, head position and estimated gestational age) could be completed by trainees in under 5 minutes, important when facing time-sensitive decisions in an emergency caesarean delivery.

With the aim of revising policy and training to align with the credentialing requirements of their site/country, Lathrop et al. [58] investigated the introduction of a learner portfolio (documented evidence of didactic learning, teaching resources, logged cases and images) and evaluation rubric to demonstrate competence. This approach is consistent with other accrediting authorities’ requirements of scanning logs and evidence of completing a pre-set number of studies. Lathrop et al. [58] was the only study whose participants all progressed to formal accreditation in the use of antenatal PoCUS.

It should be noted many of the reviewed studies were outreach projects that aimed to maximise training opportunities in low-resource settings. While minimal trainee assessment may have been undertaken by some, it is possible that the methods reported were not the only means of assuring trainee competence. Ideally, some form of competence assessment should be performed and support options provided before trainees perform unsupervised clinical scanning. All studies concluded positively regarding the PoCUS training intervention investigated. The outcomes investigated by each study and their main findings are summarised in **Table 3**.

### Barriers to PoCUS following training

Longer-term follow-up training and skills assessments, essential to building confidence and ensuring

competence and retention of learning [36], was lacking in over half of the reviewed studies. Insufficient onsite supervising experts on return to clinical practice was also a recurrent theme [21,29,51,56,58,66,67]. This problem is further compounded in some locations by poor telecommunications access, which impedes off-site assistance [22,51,66]. In such cases, telehealth, which is emerging strongly in the wake of the COVID pandemic, would be ineffective as a tool for real-time support of trainees. Several articles in this review offered off-site asynchronous expert image review for quality assurance and feedback [26,45–47,51]. This solution is inadequate in cases where technical hands-on correction is required or immediate image review is needed to guide patient management in an emergency.

Another common barrier included access to quality ultrasound equipment following training. Henwood et al. [53] reported some trainees did not have routine access to ultrasound and the ability to save images from completed examinations, and in Westerway [50], not all trainees scanned patients on return to work due to no or poor/faulty equipment. Busy departments allowing little time for scanning or supervision was another reported barrier. Half of the midwives surveyed in Kimberly et al. [62] reported difficulty finding time to perform ultrasound due to heavy clinical workloads and raised concerns over neglecting other clinical obligations. Almost half of the participants surveyed by Shokoohi et al. [51] listed ‘*lack of time to scan*’ as the main perceived challenge integrating PoCUS into patient care.

### Limitations and quality of the reviewed studies

There was a distinct lack of pedagogy described by the reviewed studies. Only Westerway [50] provided a detailed discussion describing the New World Kirkpatrick training evaluation model. Elements of pedagogy were present in other studies’ designs. For example, a constructivist, flipped classroom approach was utilised by a number of training programs [22,51,52,63], but limited description of the principles and foundations of this model were provided.

Generally, the studies suffered from limitations and biases inherent in research conducted in remote settings, including small study designs- low participant numbers, convenience samples, and loss to follow-up. A lack of longer-term follow-up of trainee outcomes was a reported limitation of many of the reviewed studies [46,49,62,66,67]. This is likely the result of geographic isolation, finite funding and an overburdened and transient health workforce [68,69]. Of those that did follow trainee progress, comparison of participants was confounded for some by inconsistent ultrasound exposure on their return to different workplaces, with varying onsite assistance and

OSCE- Objective Structured Clinical Examination  
PoCUS- Point-of-Care Ultrasound

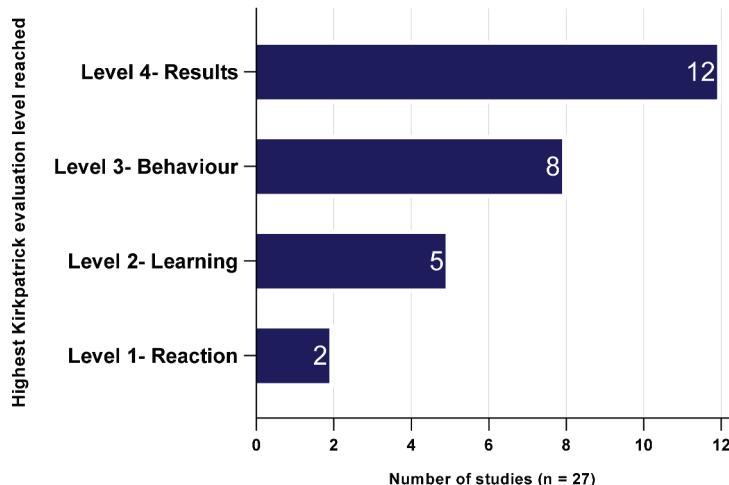

supervision between sites. Eleven of the studies performed expert review of trainee images, most asynchronously with the expert unable to perform concurrent scanning to verify trainees' findings [49,58,63]. Blinded image review was specified by several authors [45,70] to mitigate this shortcoming. Poor and worsening participant compliance with patient data recording and image logs was reported by several studies [62,66], some basing image review and quality control on scans selected for uploading by the trainees, potentially biasing results [49].

The overall quality of studies and their evidence varied, with the MERSQI assessment scores ranging from 7.5 to 18 out of 21 (mean score of 12.9). The review lacked randomised, controlled studies necessary to achieve a top MERSQI score. The upper KEF levels 3 and 4 were reached by 3/4s of the included studies. Studies reaching KEF levels 1–2 had an average MERSQI score of 11.2 and KEF Levels 3–4 averaged 13.5. Figure 3 illustrates the KEF level reached by the included studies and corresponding average MERSQI score. Table A5 of the Appendix presents the MERSQI evaluation of each reviewed study inclusive of corresponding KEF level and colour coded bias assessment ranking. The limited use or reporting of conceptual frameworks and models underpinning the development of the educational programs reviewed is reflected in the generally low MERSQI validity scores and underpinning bias ratings; categories commonly underreported in medical education research [71,72]. However, it should be noted that 'limited reporting' increases the risk of bias but does not necessarily mean the educational development is of poor quality [72].

## Discussion

This review identified 27 observational studies of moderate to low quality within the specified eligibility criteria despite an inclusive search strategy (obstetric or obstetric inclusive PoCUS training of professionals from any healthcare discipline globally). Description of theoretical concepts or pedagogy underpinning the training programs was generally lacking. Substantial heterogeneity in training formats was found between the reviewed studies, and half lacked follow-up support, training and assessment important to the safe ongoing practice of PoCUS (see Table A4- **Training methods and delivery**). The studies' findings were generally positive, reporting improved knowledge (where pre- and post-assessments were conducted), and competence being attained despite the substantial variation in course durations (3 hours to several years). Variation in competence assessment and levels of evidence was also observed (see Table 4- **Trainee and course evaluation**), with 11 of the 27 studies not surpassing KEF levels 1 or 2 of assessing immediate

### KEF Level and average total MERSQI score of the reviewed studies

KEF Level reached	1 - Reaction	2 - Learning	3 - Behaviour	4 - Results
Number of studies	2	5	8	12
Average MERSQI score	8.3	12.4	12.8	13.9

**Figure 3.** Kirkpatrick evaluation level reached by the reviewed studies.

reaction to training and knowledge gained. This is a recognised trend in which medical education researchers commonly cease evaluation at the lower KEF levels, finding longer-term investigations required for evaluations at levels 3 and 4 difficult to accomplish [73,74]. This is especially the case for PoCUS training research, which is predominantly conducted in low-resource settings where additional logistical challenges exist.

We identified several recently published systematic reviews of PoCUS training [36,75–77]. All were limited to the instruction of medical physicians, excluding allied health professionals. Other differences included setting, with Rajamani et al. [36] (2020) and Andersen et al. [76] (2019) focusing on general practice and critical care, respectively. Dickson et al. [77] (2017) included studies of trainees with no prior formal ultrasound training only. Consistent with this review's findings, variation in teaching curriculum and assessment methods, and an overall low standard of study quality were unanimously reported.

Rajamani et al. [36] reported a distinct lack of high-quality evidence on PoCUS competence, with two-thirds of the reviewed studies failing to describe important details on how assessments were conducted, and very few utilising bias minimisation strategies important to observational study designs [78]. None of the 42 studies identified by Rajamani et al. performed follow-up repeat assessments essential to assessing learning retention and safety to practice, and most of the educational programs reviewed failed to follow recommended processes for assessing PoCUS competence.

Anderson et al. [76] found a '*great variety of pedagogic approaches*' and substantial disparity in training durations (2 to 320 hours) between their included studies, which were reported to be of '*low quality... mainly because of issues with design and reporting*'. Assessment methods also varied but focussed PoCUS scans were found to require less training. Higher diagnostic accuracy and frequency of clinical use was also reported for obstetric indications, consistent with the findings in this review. These outcomes, and the need to use non-ionising imaging modalities in pregnancy highlight the utility of antenatal PoCUS in the hands of appropriately trained healthcare providers.

#### Strengths and limitations of this review

This literature review has relevance to medical educators, researchers, clinicians and policymakers interested in developing curriculum and translating PoCUS safely into clinical practice. To the authors' knowledge, this is the first published systematic review of worldwide antenatal PoCUS training of multidisciplinary healthcare clinicians. It provides comprehensive tables summarising the reviewed studies PoCUS teaching and evaluation methods. The variable training and evaluation methods described and limitation in reporting made direct comparison of study results for metanalysis unfeasible, meaning effective and ineffective training approaches could not be confidently discerned. Whether one approach to training and assessment was superior to another could not be reliably established, limiting this review. Such

heterogeneity, while complicating synthesis of evidence, can offer the advantage of examining the consistency of findings and generalizability of interventions across studies, assessing the relative feasibility of different educational approaches [71,79]. While the level of evidence and detail in reporting was lacking in many of the reviewed studies, a strength of this review is evident in the identification of this gap and the onus for more comprehensive and comparable longer-term studies with which to establish a stronger evidence base for antenatal PoCUS. An inclusive search string with broad criteria ensured a wide cross-section of antenatal PoCUS studies could be scrutinised. However, only two peer reviewed medical databases (MEDLINE and EMBASE) were searched and 'English only' articles included. Published studies from non-English-speaking countries in particular would have been missed.

### **Recommendations for future research and practice**

Robust clinical studies demonstrating the efficacy of training models, and the clinical impact of trainee operated antenatal PoCUS on quality of care and maternal/fetal outcomes are needed. Economic analyses investigating the cost-effectiveness of PoCUS training and implementation would be valuable to justify and inform future programs.

The use of Telehealth with antenatal PoCUS for real-time scanning assistance (Teleultrasound) in the clinical setting also merits further investigation, along with Artificial Intelligence systems that have the capacity to assist minimally trained operators in unsupervised clinical environments [80]. Advancements in Teleultrasound systems now make it possible for the remote clinician to view the ultrasound monitor, images and probe position, communicate via live video and text message with the operator, and even take control of the ultrasound machines functions and demonstrate findings to the patient, all in real time [81]. Many of the reviewed studies are unlikely to have the resources and infrastructure (quality internet/broadband) to support such advanced systems, but they do offer considerable advantages for remote supervision of ultrasound trainees and may see greater utilisation in the future as the technology becomes more affordable.

Only one article in this review reported on the patient experience. Vinayak et al. [63] surveyed patients, reporting they felt trainee performed PoCUS during antenatal care was safe, convenient & reassuring, providing a better antenatal visit experience, increased confidence in care delivery and increased spouse attendance. Considering the propensity for cultural minorities to live in remote communities and the underutilisation of Antenatal care

services in these regions [82–84], investigating the patient and partners' perspective on trainee provided antenatal ultrasound would be beneficial to inform curriculum development with an aim to providing culturally sensitive patient centred care.

### **Conclusion**

PoCUS is an increasingly utilised diagnostic tool that can enhance the physical exam and guide clinical decision making. It has particular utility in rural clinical practice and developing countries, where advancements in ultrasound equipment and telemedicine are opening new avenues for its establishment. Its lack of regulation and rapid expansion into most specialties underscores the need to establish standards in PoCUS training, competency and on-the-job scanning, ensuring providers are safe to practice. Acknowledging the urgent need for these skills and the difficulty accessing training in remote areas, regulation must be implemented carefully to preserve the time and financial advantages offered by PoCUS training.

Quality education programs require careful and informed consideration in their initial course design, with ongoing review of curricula, training resources, knowledge/practical skills assessment, availability of expert trainers, follow-up support and evaluation. Overall, findings from this review support intensive PoCUS training courses for task-shifting and upskilling of the medical and allied health workforce. However, significant heterogeneity in training, evaluation and research methodologies in the included studies was observed. Quality longitudinal studies with comparable evidence are needed to help frame policy guidelines and inform validated antenatal PoCUS training programs, ensuring the safe implementation of this valuable healthcare resource.

### **Acknowledgments**

We thank the Hospital Research Foundation for their funding and support of our research- The Healthy Newborn Project, which has provided outreach antenatal PoCUS training for remote Australian clinicians.

### **Funding**

This work was part of a larger project, The Healthy Newborn Project, funded by The Hospital Research Foundation.

### **Authorship declaration**

The authorship listing conforms with the journal's authorship policy. All authors (AB, EB, NP) contributed to the review's design, data acquisition, inclusion and interpretation, and were involved in drafting, revision and final approval of the manuscript.

			21

Adapted from the **Medical Education Research Study Quality Instrument (MERSQI)** [41,42].

\*Categories added- Number of trainees (score of 0.5 to 1.5); Follow-up of training (score of 0 to 3).

Categories omitted- Response rate (%).

Possible score range from 5 to 21 (original MERSQI instrument 5 to 18).

**Table A3. Risk of bias assessment tool [72]:**

Bias Source	High quality	Unclear quality	Low quality
<b>Underpinning bias (U)</b>	Clear and relevant description of theoretical models or conceptual frameworks that underpin the development	Some limited discussion of underpinning, with minimal interpretation in the context of the study	No mention of underpinning
<b>Resource bias (R)</b>	Clear description of the cost / time / resources needed for the development	Some limited description of resources	No mention of resources
<b>Setting bias (S)</b>	Clear details of the educational context and learner characteristics of the study	Some description, but not significant as to support dissemination	No details of learner characteristics or setting
<b>Educational bias (E)</b>	Clear description of relevant educational methods employed to support delivery	Some educational methods mentioned but limited detail as to how applied	No details of educational methods
<b>Content bias (C)</b>	Provision of detailed materials (or details of access)	Some elements of materials presented or summary information	No educational content presented

Note- 'Poor/limited reporting' increases the risk of bias and does not necessarily mean the educational development is of poor quality. Low quality limits utility for readers in determining transferability of the educational development [72].

**Table A4.** Training methods and delivery.

First author Year Published	Location Rural / Urban Income classification	Training duration & delivery	(Number, role/discipline, previous US experience)	(Qualification of instructor/s & ratio of instructor to trainees)	Instructors		Curriculum Course topics & Practical skills taught (Obstetric only or multiple organs systems)	Follow-up training & support (Refresher training, follow-up assessment, distance or online support & mentoring provided/ offered)
Adler [66] 2008	Africa, Tanzania (refugee camp) Rural LMIC	4 days- Morning lectures followed by afternoon practical.	Multidisciplinary 10 trainees- 4 Physicians, 6 Clinical officers. US experience not specified/unclear.	Instructor credentials and group sizes not specified.	Multiple systems- Basic US physics, knobology, & reviews of clinical US including: <b>US evaluation of 1<sup>st</sup> trimester pregnancy; Pregnancy dating &amp; fetal position;</b> FAST; US evaluation of the abdominal aorta; Hepatobiliary US; US-guided procedures; Soft tissue US; Basic echocardiography; Renal US.	Follow-up at 2 years- 1 instructional session to reinforce prior learning.		
Baltarowich [61] 2009	Africa- Sub-Saharan (Training conducted in USA) LMIC	3 months- didactic lectures, case review sessions, informal teaching sessions, conferences, hands-on sessions using a variety of equipment, & clinical observation rotations.	12 Physicians- 11 radiologists, 1 intern. US experience- 2 to 20+ years.	Training groups of 6. 1:6	Multiple systems- <b>Focus on OBs with In-depth training in: US physics, instrumentation, cross-sectional anatomy, abdomen, OB/GYN.</b> Overview of diagnostic US in the areas of vascular, echocardiography, musculoskeletal, paediatrics, thyroid, prostate, sonomammography, & interventional techniques. Care & maintenance of US equipment, preparation techniques for effective teaching.	Follow-up written test after 6 months, 8/12 trainees returned for a 4 week update program at 12 months.		
Bell [22] 2016	Africa, Kenya Rural LMIC	1 day & 1-2 follow-up sessions offered every 3-5 months for 1 year.	Multidisciplinary 81 trainees- Equal proportion of doctors, nurses & clinical officers. Several sonographers & 1 lab assistant. Most with no US experience.	US credentialed EM physicians. 4-5 trainees in practical sessions. Ratio 1:4-5	Multiple systems- Physics & machine use; <b>OB exam for intrauterine pregnancy, cul-de-sac fluid, FH activity &amp; position;</b> The abdominal, pleural & cardiac assessment for free fluid; The thoracic exam for pneumothorax.	1-2 follow-up refresher sessions offered at 3 to 5 months.		
Dalmacion [25] 2018	Asia, Philippines Rural & urban study sites LMIC	2-3 days- Classroom lectures & hands-on training. 2-3 days scanning pregnant women recruited by the study.	Multidisciplinary 20 trainees- 6 doctors, 9 midwives, 5 nurses. US experience not specified/unclear.	Credentialed OB sonographers. All lectures delivered by team leader.	Obstetrics only- Trained to identify & measure 5 OB US images.	*NR

**Table A4.** (Continued).

First author Year Published	Location Rural / Urban Income classification	Training duration & delivery	Trainees (Number, role/discipline, previous US experience)	Instructors (Qualification of instructor/s & ratio of instructor to trainees)	Curriculum		Follow-up training & support (Refresher training, follow-up assessment, distance or online support & mentoring provided/ offered)
					Course topics & Practical skills taught (Obstetric only or multiple organs systems)		
Dornhofer [54] 2020 Indonesia, East Java Urban LMIC	4 weeks- 6 sessions (3–4 days apart), 6 hours of lectures & 18 hours of practical.	Multidisciplinary	51 Trainees- 19 physicians, 19 midwives, 13 nurses. 36 (65%) had no prior US exposure, 40 (73%) observed US in practice, 4 (7%) attended prior US course.	8 Medical students- 1st year of medical education completed including- lectures on PoCUS for 8 organ systems & 10 hours of supervised hands-on training per organ system, assessment using healthy volunteers. Ratio 1:4 or 1:5 for hands-on training, 2 medical student instructors per US machine/ station to 10 trainees.	Multiple systems- 1. Basic US including US physics, machine knobology, probe manipulation, & scanning techniques. 2. Pulmonary US, evaluation of pneumothorax, pleural effusions, & pneumonia. 3. Cardiac US in the parasternal long axis view, parasternal short axis view, apical four chamber view, & subxiphoid view. 4. Abdominal US- hepatic, biliary, renal, intestinal, aorta, & inferior vena cava.	*NR	
					5. OB/GYN US including identification of intrauterine pregnancy, estimated GA, visualization of the ovaries, & bladder.		
					6. Combination of previous sessions to aid FAST & the Focused Assessment with Sonography for HIV-Associated Tuberculosis (FASH).		
Henwood [53] 2017 Africa, Rwanda Rural LIC	10-day course. 6 months scanning assessment for image accuracy.	17 Physicians-US experience not specified/ unclear.	EM physicians with expertise in PoCUS, consultant obstetricians & radiologists.	Multiple systems- Introduction to PoCUS & common applications. <b>OBs- Gestational sac, Yolk sac, Fetal pole, FHR, Endomyometrial mantle, CRL, BPD, FL, Fetal lie, placental location, Placenta previa, Hydramnios.</b>	Multiple systems- Introduction to PoCUS & common applications. <b>OBs- Gestational sac, Yolk sac, Fetal pole, FHR, Endomyometrial mantle, CRL, BPD, FL, Fetal lie, placental location, Placenta previa, Hydramnios.</b>	Follow-up training every 6 weeks for 6 months trial period with regular practical assessments. Onsite image review & technical assistance.	
Kimberly [62] 2010 Africa, Zambia Rural LMIC	6 months- 3 training periods of 2 to 3 weeks interspersed by 2 to 3 months of independent scanning under minimal supervision	21 Midwives- No prior US experience.	3 emergency US fellowship trained physicians.	Obstetrics only- US machine use, cleaning & storage, Patient data entry, image saving (for review), & exam datasheet completion.	1 year follow-up visit questionnaire of PoCUS application & frequency, no additional training.

**Table A4.** (Continued).

<b>First author</b>	<b>Year Published</b>	<b>Location Rural / Urban</b>	<b>Income classification</b>	<b>Training duration &amp; delivery</b>	<b>Trainees</b> (Number, role/discipline, previous US experience)	<b>Instructors</b> (Qualification of instructor/s & ratio of instructor to trainees)	<b>Curriculum</b> <b>Course topics &amp; Practical skills taught</b> (Obstetric only or multiple organs systems)	<b>Follow-up training &amp; support</b> (Refresher training, follow-up assessment, distance or online support & mentoring provided/ offered)
Kolbe [26]	2015	Central America, Nicaragua	Rural & urban study sites LMIC	Daily morning didactic sessions & practical workshops, afternoon US of patients from the community (course duration unclear), followed by 3 months remote guidance & telecommunication.	Multidisciplinary 4 trainees- 2 postgraduate rural medicine physicians, 1 nurse, 1 nursing assistant. US experience not specified/unclear.	Experienced international sonographers. Ratio 1:4.	Multiple systems- <b>OBs- Normal pregnancy, Fetal viability; Complicated pregnancy (Ectopic pregnancy, Placenta previa, Placenta abruption).</b> Other systems- Echocardiography, Hemodynamic evaluation, Pleural, Lung, Abdominal & Vascular US.	Weekly 60-90 min remote guidance sessions & telecommunication support for 3 months following training.
Kotagal [56]	2015	USA, Washington	Urban aimed at rural deployment HIC	14 hours- 7 sessions of 2 hours over 3 months.	16 General surgery residents-Limited previous US training (guidance for central venous catheter placement & a brief FAST training).	Multidisciplinary faculty (Surgery, Radiology, Anaesthetics & EM) with expertise in PoCUS.	Multiple systems- Topics- US physics, knobology, safety & artifacts; FAST; Skin & soft tissue US; <b>OB US (early &amp; late pregnancy); Focused echocardiography &amp; volume assessment; Procedural guidance US (paracentesis, thoracentesis, &amp; pericardiocentesis); Vascular US (abdominal aorta &amp; deep vein thrombosis); US guided regional anaesthesia.</b>	*NR
Lathrop [58]	2011	USA, Indianapolis	Urban HIC	Half day workshop- 45 minute instruction session followed by practical.	4 Advanced practice Nurses (APN)- 3 attended previous didactic US training.	Credentialed US provider. Ratio 1: 2-3 for practical workstations.	Obstetric Only- Instruction session (45 mins)- Review US standards of care, basic review of US physics & instrumentation, indications, clinical significance & documentation. Practical session- Fetal number, demonstration of life, estimate amniotic fluid, placenta location & fetal presentation.	No follow-up of trainees reported but an additional future workshop planned to include more advanced skills, such as fetal biometry, first-trimester US, & cervical length measurement.

(Continued)

Table A4. (Continued).

First author	Year Published	Location Rural / Urban	Income classification	Training duration & delivery	Trainees (Number, role/discipline, previous US experience)	Instructors (Qualification of instructor/s & ratio of instructor to trainees)	Curriculum (Obstetric only or multiple organs systems offered)	Follow-up training & support (Refresher training, follow-up assessment, distance or online support & mentoring provided/offered)
Lee [55]	2017	Indonesia, Bandung	Urban	4 weeks – 6 sessions. Each session- 30 min lecture followed by 2 hours hands-on training.	41 Physicians- 22 (53.7%) no prior US experience, 18 (43.9%) observed US in practice, 1 (2.4%) attended prior US course.	Medical students- 1 st year of medical education completed including- lectures on PoCUS for 8 organ systems & 10 hours of supervised hands-on training per organ system, assessment using healthy volunteers.	Multiple systems- 6 sessions, 38 US milestones. 1- Basic US including physics, knobology, probe manipulation & scanning techniques. 2- Pulmonary US, evaluation of pneumothorax, pleural effusions & pneumonia. 3- Cardiac US in the parasternal long axis view, parasternal short axis view, apical four chamber view & subkiophoid view. 4- abdominal US (hepatic, biliary, renal, intestinal, aorta & inferior vena cava). 5- OB/GYN US (identification of intrauterine pregnancy, estimated GA, visualization of the ovaries & bladder).	Follow-up scheduled for 12 months to re-test trainees & assess use of US.
Lindgaard [52]	2017	Denmark, Odense	HIC	2 days practical & feedback session following online learning package.	5 General Practitioners- 4 specialist GPs, 1 final year resident. No formal US training.	Instructors from Center of Clinical US, University of Aarhus.	Multiple systems- E-learning online lectures- Basic US knowledge- physics & US equipment; Focused US examinations of thoracic structures, abdomen, vascular & musculoskeletal.	*NR
Mandavia [67]	2000	USA, California	Urban	16 hours over 2 days. 8 hours lectures & 8 hours practical.	Multidisciplinary 80 trainees- 16 attending physicians, 53 ED house officers, 4 physician assistants, 7 medical students.	Board certified US trained EM physicians & certified registered diagnostic medical sonographers. Ratio 4:1 per US/station for hands-on learning.	Multiple systems- Curriculum based on Society for Academic Emergency Medicine guidelines. Lectures- Basic physics; Pelvis & OB; Right upper quadrant; Renal; Aorta; Trauma: Echocardiography, Practical- OB skills included: <b>Detection of early intrauterine pregnancy &amp;/or free pelvic fluid; Detection of live fetus in 2<sup>nd</sup>/3<sup>rd</sup> trimesters.</b>	Follow-up identical test at 10 months & images performed over this time reviewed for accuracy.

(Continued)

Table A4. (Continued).

First author	Year Published	Location Rural / Urban	Income classification	Training duration & delivery	Trainees (Number, role/discipline, previous US experience)	Instructors (Qualification of instructor/s & ratio of instructor to trainees)	Curriculum Course topics & Practical skills taught (Obstetric only or multiple organs systems)	Follow-up training & support (Refresher training, follow-up assessment, distance or online support & mentoring provided/ offered)
Nathan [49]	2017	2 weeks- One third didactic sessions, two thirds practical scanning. 5 sites: Democratic Republic of Congo, Karawa Guatemala, Chimaltenango Kenya, Eldoret Pakistan, Karachi Zambia, Lusaka Rural LIC/LMIC/UMIC	Multidisciplinary	41 Trainees- 10 medical officers, 18 nurses, 6 midwives, 7 radiographers. No prior US experience.	Training under the direction of a Radiologist. Local sonographer for ongoing training, QA & trainee evaluation.	Obstetric only- Curriculum development- Didactic & hands-on instruction, printed materials, extensive quality assurance activities, educational outreach visits, daily schedule, speaker notes for PowerPoint slides, & explicit instructions for each practical scanning session.	For the 12 week pilot period- Monthly follow-up & practical assessment. Local instructors met trainees to discuss performance & observe scanning progress bi-weekly. Image feedback from quality control website.	
Rominger [24]	2018	Mexico, Chiapas Rural	Multidisciplinary	16 days training over 12 month duration. Total of 4 sessions (each session 4 day course) every 3-4 months.	10 Physicians-Little to no prior US experience.	Obstetrician, Paediatric EM physician, EM physician & residents. 6 to 10 trainees per 2 instructors. Ratio 1:3-5	Image review by: Radiologist (25 yrs in OB US), 2 professors of OBs; a professor of radiology (10 yrs in OB US); & 2 lead OB sonographers.Training groups of 4 to 12 – ratio not specified.	Targeted remedial training given to some trainees.
Shah [45]	2020	Africa, Uganda	Multidisciplinary	2 days intensive training course followed supervised (Master trainer) scanning 2-3 days per week for 3 weeks.	25 Trainees- 20 midwives, 3 nurses, 2 physicians. No prior US experience.	Certified sonographer, OB/GYN resident physician, family physician & 3 EM physicians with US training. Instructors had prior experience in PoCUS in LMIC. Ratio 1:3 for practical scanning.	Twice weekly distance/online communication for 3 months. Confidence survey repeated at 3 months. Key informant interviews assessed trainee' perception of training program	Topics- US knobs & Physics; US Safety; Principles of adult learning; US teaching methods; Hands-on training techniques; Fetal position; Placental position; Fluid volume; Multiple gestation; FHR; Estimating GA; BPD, HC, FL, TCD; Common learner mistakes.

<b>First author</b>	<b>Year Published</b>	<b>Location Rural / Urban Income classification</b>	<b>Training duration &amp; delivery</b>	<b>Instructors</b> (Number, role/discipline, previous US experience)	<b>Curriculum</b> (Qualification of instructor/s & ratio of instructor to trainees)	<b>Course topics &amp; Practical skills taught</b> (Obstetric only or multiple organs systems)	<b>Follow-up training &amp; support</b> (Refresher training, follow-up assessment, distance or online support & mentoring provided/ offered)
Shah [48]	2014	USA, North-western Urban HIC	3 hours- 1 hour lecture, 2 hours practical.	31 Emergency physicians- 17 attendings, 14 residents. Range of no prior experience to experienced.	US fellowship trained EM physicians, 1:1 for hands-on instruction.	Obstetric only- Mechanics of TA & TV US. General review of 1st trimester US including- Normal US findings in 1st trimester, Other abnormal US findings in early pregnancy (fetal demise, molar pregnancy), finding FHR using M-mode, measurement of GA using CRL, & ectopic pregnancy. Late pregnancy US including fetal lie & identification of the fetal head, & fetal biometry including measurement of BPD, FL, HC & AC. Practical- live models in the 2nd & 3rd trimester of pregnancy.	*NR
Shah [47]	2009	Africa, Rwanda Kirehe & Rwinkwavu in Eastern Province Rural LIC	9 weeks- 1 hour lecture (15 lectures total) followed by 1-2 hours practical.	10 Physicians-Little to no prior US experience.	US training sessions conducted by a 4th year EM resident with prior US experience (including OB US) during residency training & credentialing certification.	<b>OB US including 1<sup>st</sup> trimester basics- ectopic or molar pregnancy, estimating GA, &amp; evaluation of fetal position, cervix &amp; placenta.</b> Cardiac US; Hepato-biliary US; Renal US; Advanced applications-US evaluation of DVT, procedures including vascular access, abscess evaluation & drainage, US guided paracentesis & thoracentesis.	Multiple systems- Principles of US physics; Machine operation; Potential uses of US; Outline of lecture series, training expectations, image & data sheet recording instructions.
Shah [46]	2008	Africa, Rwanda, Kirehe & Rwinkwavu in Eastern Province Rural LIC	9 weeks- 1 hour lecture (15 lectures total) followed by 1-2 hours practical.	15 physicians- 0-4 h of prior US training solely in OBs.	US training sessions conducted by a 4th year EM resident with prior US experience (including OB US) during residency training & credentialing certification. Cardiac echo lecture given by visiting Cardiologist.1:1 for scanning practice during ward rounds. Other group sizes not specified.	<b>OB US including 1<sup>st</sup> trimester basics- ectopic or molar pregnancy, estimating GA, &amp; evaluation of fetal position, cervix &amp; placenta.</b> Cardiac US; Hepato-biliary US; Renal US; Advanced applications-US evaluation of DVT, procedures including vascular access, abscess evaluation & drainage, US guided paracentesis & thoracentesis.	Multiple systems- Principles of US physics; Machine operation; Potential uses of US; Outline of lecture series, training expectations, image & data sheet recording instructions.

<b>First author</b>	<b>Year Published</b>	<b>Location Rural / Urban</b>	<b>Income classification</b>	<b>Training duration &amp; delivery</b>	<b>Trainees</b> (Number, role/discipline, previous US experience)	<b>Instructors</b> (Qualification of instructor/s & ratio of instructor to trainees)	<b>Curriculum</b> (Obstetric only or multiple organs systems)	<b>Course topics &amp; Practical skills taught</b>	<b>Follow-up training &amp; support</b> (Refresher training, follow-up assessment, distance or online support & mentoring provided/ offered)
Shaw-Battista [29]	2015	USA, California Urban	HIC	10 asynchronous online modules followed by 4 hours training- 2 hour seminar, 2 hour practical.	Multidisciplinary Initial course- 72 trainees- Midwives, nurses, family practice physicians, physician assistants Developed course- 162 trainees- Midwives, nurses, nurse practitioners, medical & midwifery students, family practice & OB physicians, physician assistants. Range of no prior US experience to experienced.	Senior OB & family medicine residents (advanced trainees & licensed clinicians). Ratio 1:3-5 during practical sessions.	Obstetrics only- Asynchronous online module topics- Indications for OB US; Documentation, communication, liability, & risk-reduction strategies; US physics, equipment, & optimizing image quality; Normal 1st trimester US; Abnormal 1st trimester US; Limited 2nd & 3rd trimester US; Fetal biophysical profile; 2nd & 3rd trimester fetal biometrics; Use of OB US on the labor & delivery ward; Interprofessional OB US training & practice.	*NR	
Shokohi [51]	2019	Africa, Tanzania, Malawi & Uganda Rural & urban	LIC/LMIC	2 day training course. Online modules & educational materials provided.	Multidisciplinary 49 Trainees (initial 63 with 78% response rate)- 7 midwives, 42 physicians (different specialties). 21/49 never performed independent US, 29/49 limited US training during residency.	Sonographer. Ratio 1:3-4 during course. Ratio 1:1 for in clinic training.	Multiple systems- Topics- review of the concepts for clinician- performed US, introduction to the US machine & controls, the focused assessment with sonography for trauma/focused assessment with sonography for human immunodeficiency virus/tuberculosis (FAST/FASH), abdominal US exam, echocardiography, lung, renal/bladder & abdominal US	Telecommunication support- Online feedback on transmitted images from independent scanning after training	
Stoltz [30]	2015	Africa, Uganda	LIC	2 years- US lectures delivered intermittently over the 2-year 'emergency care for non-physicians' curriculum (train the trainer model) with the core US lectures occurring early in the programme.	13 Nurses-US experience not specified/unclear.	EM physicians with fellowship training in emergency US or strong clinical competency in emergency US.	<b>Midwives &amp; obstetricians received focused training on gynaecologic US &amp; 1<sup>st</sup> &amp; 3<sup>rd</sup> trimester US.</b>	Multiple systems- 1. Introduction to POCUS, Machine care, basic physics & US principles, image optimisation, knobology, safety, patient consent & documentation in the medical record. 2. FAST; 3. Echocardiography; 4. Hepatobiliary US; 5. Renal US; 6. Soft tissue US; 7. Lung US; 8. Aorta US; 9. Inferior vena cava US; 10. <b>OB/GYN US- Evaluation of intrauterine pregnancy, signs of ectopic pregnancy, pelvic free fluid, adnexal mass, foetal heart rate, foetal movement, fetal dating &amp; fetal presentation</b>	*NR

(Continued)

Table A4. (Continued).

First author	Year Published	Location Rural / Urban Income classification	Training duration & delivery	Trainees (Number, role/discipline, previous US experience)	Instructors (Qualification of instructor/s & ratio of instructor to trainees)	Course topics & Practical skills taught (Obstetric only or multiple organs systems)	Follow-up training & support (Refresher training, follow-up assessment, distance or online support & mentoring provided/ offered)
Swanson [85]	2014	Africa-Uganda Rural LMIC	6 weeks- Lectures, small-group tutorials, audio-visual materials & supervised clinical scanning.	14 midwives- 13 no prior US experience, 1 experienced.	Primary instructors' credentials not specified. Sonographer for ongoing scanning support.	Obstetric only- Curriculum included US physics, relevant anatomy & physiology, instrumentation & basic maintenance. Screening included- cardiac activity (yes, no), fetal presentation (cephalic, breech & others) & fetal number, Placental position (normal, previa & low lying), Pain & bleeding (complete abortion, incomplete abortion, blighted ovum, ectopic pregnancy or placental abnormality).	Ongoing training resource in onsite sonographer available to trainees on return to clinic
Vinayak [63]	2017	Africa, Kenya Outer regional & Rural LMIC	4 weeks- 1 hour lecture, 6 hours practical, 1 hour feedback & debrief per day (days per week unclear). Several days of assessment after course completion.	3 midwives- No prior US experience.	'Experienced sonographers. Ratio 1:3. Obstetrics only- 1. E-learning module- introduction to general principles of US, US physics & OB US. 2. Post module test 3. Didactic lectures- US knobology, general & OB US 4. Hands-on practical experience. Practical skills- HC, AC, FL & FHR & rhythm. Placenta location & distance of lower lip from the cervix & estimated the amount of amniotic fluid (obtained from four images, one image for each quadrant).	*NR	
Vyas [70]	2018	America, Panama (Training in USA) Rural HIC	12 hours- 6 sessions on OB US instruction, termed "Rural Obstetric Ultrasound Triage Exam" (ROUTE).	8 medical students- Prior basic US training in medical school curriculum.	Trainer- 3rd year OB/GYN resident physician. Assessment by board certified OB/GYN physicians.	Obstetric Only- ROUTE including identification of- fetal lie, placental position, DVP, amniotic fluid index (AFI), BPD, & HC for 2nd & 3rd trimester.	
Wanjiku [21]	2018	Africa, Kenya Rural LMIC	1 day practical training following self-directed online pre-training.	Multidisciplinary 33 trainees- Clinical officers, Nurses, Medical officers. All had previously completed a novel pilot PoCUS training program. Other prior US training excluded participation.	Certified Instructors.	Multiple systems- Standardized OSCE trainees assessed on - FAST (Trauma assessment), 1 <sup>st</sup> & 2 <sup>nd</sup> /3 <sup>rd</sup> trimester scanning skills, i.e., identification of the gestational sac, 1 <sup>st</sup> trimester dating using crown-rump length, detecting & measuring the FHR, identifying the presenting part, locating the placenta, & measurement of HC & BPD.	Follow-up in-facility testing scheduled 3-4 months after initial training. 3-4 month refresher training offered to trainees who failed practical assessment.

(Continued)

<b>First author</b>	<b>Year Published</b>	<b>Location Rural / Urban</b>	<b>Income classification</b>	<b>Training duration &amp; delivery</b>	<b>Trainees</b> (Number, role/discipline, previous US experience)	<b>Instructors</b> (Qualification of instructor/s & ratio of instructor to trainees)	<b>Curriculum</b> (Obstetric only or multiple organs systems)	<b>Course topics &amp; Practical skills taught</b>	<b>Follow-up training &amp; support</b> (Refresher training, follow-up assessment, distance or online support & mentoring provided/offered)
Westerway [50]	2019	Australia Rural & urban HIC Indonesia/Central Asia/ Timor Leste UMIC/LMIC	6 separate POCUS courses compared. Ranging from 4 to 18 hours total. Up to 6 hours lecture, 3–12 hours practical.	Multidisciplinary 55 trainees- 15 medical practitioners, 23 midwives, 9 nurses, 8 radiographers. No prior US experience.	Experienced OB US tutors. Same lead lecturer for all 6 courses. Ratio from 1: 2–5 (average 1:4).	Obstetric only- Curriculum- Clinical history- pregnancy progression; Knobology, image optimisation (depth, focus, gain) & probe use; Theory behind performing a limited fetal anatomical assessment & 3rd trimester fetal biometry. Practical checklist- Image optimisation; Probe movements; Fetal lie; FHR; Recognition of fetal anatomy (heart, stomach & bladder); Amniotic fluid estimate (single deepest pocket); Identification of cervix & placental position; Fetal biometry measurements (BPD, HC, AC, FL).	Follow-up test & practical at 6 & 11 months		

Key- \*NR = not reported/described

**Abbreviations**

- FH – Fetal Heart
- FHR – Fetal Heart Rate
- FL – Femur Length
- GA – Gestational Age
- HC – Head Circumference
- HIC – High-income country
- LIC – Low-income country
- LMIC – Upper-middle-income country
- LRS – Lower-middle-income country
- US – Ultrasound
- OB – Obstetric
- OB/GYN – Obstetrics and Gynaecology
- OSCE – Objective Structured Clinical Examination
- TA – Transabdominal
- TCD – Trans Cerebellar Diameter
- TV – Transvaginal
- UMIC – Upper-middle-income country
- US – Ultrasound

FAST – Focused Assessment with Sonography in Trauma

**Table A5. Quality assessment and bias ranking of included articles using a modified Medical Education Research Study Quality Instrument (MERSQI) [41,42].**

Study	Study design	Sampling	**Follow-up of training	Type of data	Validity assessment of evaluation instrument	Data analysis	Outcomes	MERSQI score	<u>Underpinning bias</u> <u>Resource bias</u> <u>Setting bias</u> <u>Educational bias</u> <u>Content bias</u>
