## ABSTRACT

### Background

Worldwide, the prevalence of obesity and overweight in industrialized countries and in a substantial number of developing countries is increasing at an alarming rate. Rimonabant is a selective cannabinoid-1 receptor antagonist that has been investigated for its efficacy in reducing body weight and associated risk factors in obese people. Phase III trials are now under way to test the use of rimonabant for long-term weight-loss. Given the prevalence of overweight and obesity, it is important to establish the efficacy and safety of rimonabant.

### Objectives

To assess the effects of rimonabant in overweight and obese people.

### Search methods

MEDLINE, EMBASE, *The Cochrane Library*, LILACS, databases of ongoing trials and reference lists were used to identify relevant trials.

### Selection criteria

Randomised controlled trials comparing rimonabant with placebo or other weight loss interventions in overweight or obese adults.

### Data collection and analysis

Two reviewers independently assessed all potentially relevant citations for inclusion and methodological quality. The primary outcome measures were weight loss change, morbidity and adverse effects occurrence.

### Main results

Four studies evaluating rimonabant 20 mg versus rimonabant 5 mg versus placebo in addition to a hypocaloric diet lasting at least one year were included. Compared with placebo, rimonabant 20 mg produced a 4.9 kg greater reduction in body weight in trials with one-year results. Improvements in waist circumference, high-density lipoprotein cholesterol, triglyceride levels and systolic and diastolic blood pressure were also seen. However, the results with rimonabant 5 mg demonstrated a weight reduction which was only 1.3 kg greater when compared with placebo. No clinically relevant effects on plasma lipids and blood pressure were found. Rimonabant 20 mg caused significant more adverse effects both of general and serious nature, especially of nervous system, psychiatric or gastro-intestinal origin. Attrition rates were approximately 40% at the end of one year.

### Authors' conclusions

The use of rimonabant after one year produces modest weight loss of approximately 5%. Even modest amounts of weight loss may be potentially beneficial. The observed results should be interpreted with some caution, though, since the evaluated studies presented some

deficiencies in methodological quality. Studies with longer follow-ups after the end of treatment and of more rigorous quality should be done before definitive recommendations can be made regarding the role of this new medication in the management of overweight or obese patients.

## PLAIN LANGUAGE SUMMARY

### **Rimonabant for overweight or obesity**

Rimonabant is the first drug of a new class of medications that seems to reduce body weight and improve risk factors for diseases of the blood vessels and heart in people who are overweight or obese. We found four studies which evaluated weight loss, occurrence of disorders and adverse effects of treatment. The four studies involved 6625 people comparing rimonabant 20 mg with rimonabant 5 mg and placebo, in combination with a hypocaloric diet after one or two years of treatment. Greater weight loss and improvement in risk factors were seen after 20 mg of rimonabant. These results have to be interpreted with caution though, due to high discontinuation rates of study participants and the overall low quality of the included studies.

We conclude that: 1. average weight loss with rimonabant appears modest, and 2. more rigorous studies examining the efficacy and safety of rimonabant are required to fully evaluate the benefit risk ratio of this new drug.

In Europe, rimonabant is contraindicated for patients with severe depression and/or patients who are treated with antidepressive medications. Rimonabant is furthermore not recommended for patients with other untreated psychiatric conditions.

## BACKGROUND

### Description of the condition

Worldwide, the prevalence of obesity and overweight in industrialized countries and in a substantial number of developing countries is increasing at an alarming rate (WHO 2000). This problem is associated with a large variety of health consequences representing an enormous burden on health care systems and, most importantly, the quality of life of the affected individuals might be substantially lowered.

Obesity refers to an excess of body fat or adiposity. Body mass index (BMI; in kg/m<sup>2</sup>) is widely recognized as a weight-for-height index that has a high correlation with adiposity. In clinical terms, a BMI of 25-29 kg/m<sup>2</sup> is classified as overweight and a higher BMI (greater than 30 kg/m<sup>2</sup>) reflects obesity (WHO 2000).

Overweight and obesity are associated with a large variety of health consequences, including hypertension (Brown 2000; Dyer 1989), type 2 diabetes mellitus (Medalie 1974; Ohlson 1985), heart diseases (NIHCD 1985; Willett 1995), stroke (Rexrode 1997; Walker 1996), osteoarthritis (Cicuttini 1996; Hart 1993), sleep apnoea and respiratory difficulties (Chua 1994) and also several common cancers (Bergstrom 2001; Chu 1991; Schottenfeld 1996).

The presence of excess fat in the abdomen out of proportion to total body fat is an independent predictor of type 2 diabetes, dyslipidaemia, hypertension and cardiovascular disease (NHLBI 1998). Waist circumference and waist-to-hip circumference ratios (WHR) are simple and convenient for epidemiological studies and provide a useful estimation of the proportion of abdominal or upper-body fat (Björntorp 1984; Björntorp 1985; Kissebah 1985). Several studies have investigated the correlation of abdominal fat and increased mortality and risk for disorders such as diabetes, hyperlipidaemia, hypertension and cardiovascular diseases (Donahue 1987; Ducimetiere 1986; Lapidus 1984; Larsson 1984; Ohlson 1985; Stokes 1985).

### Description of the intervention

Obesity is seen as a disease, which requires treatment. Treatment means, first of all, weight reduction. The general goals of weight loss and management are:

- (1) to reduce body weight; and
- (2) to maintain a lower body weight over the long term; or
- (3) at a minimum, to prevent further weight gain.

There is strong evidence that weight loss (5% to 15% of the body weight) in obese individuals reduces risk factors associated with obesity (NHLBI 1998).

Traditional methods to promote weight loss focus on reducing energy intake through low-calorie or low-fat diets, increasing energy expenditure by increase in physical activity, and behavioural modification. The inclusion of exercise in a weight reduction program is supposed to make the weight loss easier, compared with food restriction alone. However, the effectiveness of these weight reduction methods is limited, with an overall pattern of moderate weight loss followed by gradual weight regain (Curioni 2005).

Numerous other weight loss interventions are available including pharmacotherapy, surgery to reduce food consumption and alternative therapies. Surgical procedures have greater long-term success rates but are currently indicated for the very obese only (BMI greater than 40 kg/m<sup>2</sup> or BMI 35 to 40 kg/m<sup>2</sup> together with an obesity-related disorder). Operative mortality rates are reported to

average below one percent, but long-term complications such as malabsorption syndromes may occur (Greenway 1996).

Pharmacotherapy should be considered in overweight and obese patients with a BMI greater than 27 kg/m<sup>2</sup>, particularly in the presence of comorbidities or an increased waist circumference, when conservative measures such as behaviour therapy, diet and exercise have not resulted in the desired weight loss (NHLBI 1998). Drugs should always be used in conjunction with non-pharmacological therapy, though.

Approved anti-obesity medications can be divided into two broad categories:

(1) Inhibitors of intestinal fat absorption, where the only agent currently available compound in this class is orlistat, a drug that inhibits pancreatic and other lipases. Side effects are related to malabsorption of fat within the gastrointestinal tract and include steatorrhea, bloating, and oily discharge. Fecal incontinence and malabsorption of fat-soluble vitamins, such as vitamin A, D, E, and K, have also been reported (McNeely 1998).

(2) Drugs that act to suppress appetite. An example of this category includes sibutramine, which inhibits re-uptake of serotonin and norepinephrine. The most common adverse effects are related to increased adrenergic activity and include dry mouth, headache, insomnia, and constipation. Sibutramine may also cause increases in blood pressure and heart rate (Luque 1999).

Orlistat and sibutramine are the only medications approved for long-term use.

A number of anti-obesity drugs are currently undergoing clinical development. These include:

- (1) Centrally-acting drugs, such as the noradrenergic and dopaminergic re-uptake inhibitor rodafaxine, the endocannabinoid antagonist rimonabant, the selective serotonin 5-HT<sub>2C</sub> agonist APD-356, and oleoyl-estrone;
- (2) Drugs that target peripheral episodic satiety signals, such as glucagon-like peptide-1, peptide YY and amylin;
- (3) Drugs that block fat absorption, such as the novel lipase inhibitors cetilistat and GT-389255; and
- (4) A human growth hormone fragment (AOD-9604) that increases adipose tissue breakdown (Halford 2006).

Most of these investigational drugs are in the early or mid-stages of development. Rimonabant is the only drug in the late-stage of investigations.

### How the intervention might work

Rimonabant is a selective cannabinoid-1 receptor antagonist that has been investigated for its efficacy in reducing body weight and associated risk factors in obese people (Bonner 2005). The cannabinoid-1 receptor plays a role in the regulation of appetite and body weight. The endocannabinoid system (EC) consists of cannabinoid receptors (CB<sub>1</sub> receptors) and endocannabinoids, as well as enzymes catalysing their biosynthesis and degradation (Di Marzo 2005). CB<sub>1</sub> receptors are expressed predominantly in several areas of the brain and in peripheral organs, including the autonomic nervous system, liver, muscle, gastrointestinal tract, and adipose tissue (Di Marzo 2004). Pharmacological stimulation of CB<sub>1</sub> receptors by systemic administration of plant or endogenous cannabinoids stimulates eating, even in satiated animals (Colombo 1998; Rowland 2001; Simiand 1998).

The administration of the first selective CB<sub>1</sub> antagonist (rimonabant) attenuated agonists' stimulatory effects on food

intake and strongly reduced both the consumption of palatable food (such as sweet food) and the intake of normal food by animals deprived of food (Rinaldi-Carmona 2004; Werner 2003).

The EC system may regulate food intake by modulating actions or expressions of many anorectic and orexigenic mediators in the brain, particularly hypothalamic peptides such as corticotrophin-releasing hormone (CRH) and melanin-concentrating hormone (MCH). Of particular importance are the effects of endocannabinoids on the mesolimbic system that modulates reward behaviours (such as food intake as a reward after managing stressful situations). Endocannabinoids enhance dopamine release in the nucleus accumbens, thus increase the drive to eat (Di Marzo 2005). Rimonabant has been shown to reduce food intake, hunger and body weight in overweight or obese men after seven days of treatment (Vickers 2005).

Phase III trials are now under way to test the use of rimonabant for long-term weight-loss. Four clinical trials (RIO (rimonabant in obesity) RIO-North America, RIO-Europe, RIO-Diabetes and RIO-Lipids) involving 6000 participants suggest that rimonabant 20 mg produces a placebo-subtracted weight loss of approximately five kg. No major side effects were reported; however, given the wide distribution of CB<sub>1</sub> receptors within the body, it is possible that the drug could affect a number of systems unrelated to eating (Halford 2006).

A Cochrane systematic review is being developed to analyse the efficacy of cannabinoid type 1 receptor antagonists for smoking cessation (Hey 2005)

### Important adverse effects

In Europe, rimonabant is contraindicated for patients with severe depression and/or patients who are treated with antidepressive medications. Rimonabant is furthermore not recommended for patients with other untreated psychiatric conditions.

### Why it is important to do this review

There is no systematic review evaluating the efficacy and also the possible adverse effects of rimonabant in overweight or obese people. Given the prevalence of overweight and obesity, it is important to establish the possible impact of rimonabant in people suffering from these conditions.

## OBJECTIVES

To assess the effects of rimonabant in overweight and obese people.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

Only randomised controlled trials were considered for inclusion.

#### Types of participants

Individuals aged 18 years and older defined as overweight or obese at baseline. Criteria for defining overweight or obesity include BMI cut-off points (WHO 2000). Ideally, diagnostic criteria should have been described. If necessary, authors' definition of overweight or obesity were used and eventually subjected to sensitivity analysis.

Studies including children, pregnant women, or patients with serious medical conditions would have been excluded.

### Types of interventions

Interventions eligible for inclusion in the review included:

- Rimonabant versus placebo;
- Rimonabant plus other interventions such as diet or exercise versus placebo plus the same intervention;
- Rimonabant versus any other pharmacological intervention;
- Rimonabant versus a non-pharmacological intervention.

### Types of outcome measures

#### Primary outcomes

To be eligible for inclusion in the review, trials had to report one or more of the following outcomes:

- change in weight measures (for example body weight, body mass index (BMI), waist circumference or hip/waist circumference, other anthropometric measures);
- morbidity (such as cardiovascular disorders, gastrointestinal disorders, nervous system disorders, psychiatric disorders, renal and urinary disorders);
- adverse effects of treatment (such as headache, nausea, anxiety, insomnia, gastrointestinal symptoms)

#### Secondary outcomes

- all-cause mortality;
- change in risk factors (such as blood pressure, lipid profile and HbA<sub>1c</sub>);
- health-related quality of life (ideally using a validated instrument);
- Costs.

#### Specific patient covariates thought to be effect modifiers

- compliance with the treatment;
- initial overweight or obesity;
- duration of the intervention.

#### Timing of outcome assessment (duration of the intervention)

- short-term (four weeks to 24 weeks of treatment);
- medium-term (more than 24 weeks to 12 months of treatment);
- long-term (more than 12 months of treatment).

### Search methods for identification of studies

#### Electronic searches

The following electronic databases were searched to identify relevant trials, reviews, meta-analyses, and economic analyses:

- *The Cochrane Library* (issue 3, 2006);
- MEDLINE (up to June 2006);
- EMBASE (up to June 2006);
- LILACS (up to June 2006);

There were no language restrictions for either searching or trial inclusion. The search strategy using a combination of MeSH terms and text words was used for MEDLINE and was adapted to suit the

other databases. For a detailed search strategy, please see under [Appendix 1](#).

### Databases of ongoing trials

- Current Controlled Trials (<http://www.controlled-trials.com/>);
- National Research Register (<http://www.update-software.com/National/nrr-frame.html>);
- National Institutes of Health (<http://clinicalstudies.info.nih.gov/>)

### Searching other resources

Efforts were made to identify additional studies by searching the references lists of relevant trials and reviews identified.

Authors of relevant identified studies and other experts were contacted to obtain additional references, unpublished trials, ongoing trials and missing data not reported in the published trials.

### Data collection and analysis

#### Selection of studies

Two reviewers (CC and CA) independently scanned the titles, abstracts and keywords of trials identified through the respective search strategies. The articles were evaluated for inclusion whenever there was a suggestion that they:

- Included patients with overweight or obesity;
- Compared rimonabant with placebo or another active intervention;

Articles were rejected on initial screen if both reviewers could positively determine from the title and abstract that they did not meet the inclusion criteria. All potentially relevant articles were investigated as full text. Agreement between the two reviewers was expressed using the kappa statistic ([Cohen 1960](#)). Eventual disagreement was resolved by discussion between the reviewers. Excluded studies and the reasons for exclusion were clearly reported in a specific table.

#### Data extraction and management

Two reviewers (CC and CA) independently extracted data from each study using standard data extraction forms (for details see [Characteristics of included studies](#) and [Table 1](#); [Appendix 2](#); [Appendix 3](#); [Appendix 4](#); [Appendix 5](#)). Differences between reviewers' extraction results were resolved by discussion. The standard data extraction forms included the following items:

- General information: published or unpublished, title, authors, source, contact address, country, language and year of publication, duplicate publications, sponsoring, and setting;
- Participants: sampling (random or convenience), exclusion criteria, total number and number in the compared groups; age; gender; initial BMI, assessment of compliance, similarity of groups at baseline (including any co-morbidity), withdrawals or losses to follow-up (reasons or description), subgroups;
- Trial characteristics: design, duration, randomisation (and its method), allocation concealment (and its method), blinding (patients, people administering treatment, outcome assessors), and check of blinding;
- Interventions: types, duration, description (schedule, dose, route, timing, etc.);

- Outcomes: outcomes specified above, any other outcomes assessed, other events, length of follow-up, quality of reporting of outcomes;
- Results: measures of effect specified above, use of intention-to-treat analysis.

### Assessment of risk of bias in included studies

Two reviewers evaluated independently methodological quality of trials by means of individual quality component analysis (CC and CA). Inter-rater agreement was planned to be calculated using the kappa statistic ([Cohen 1960](#)). Studies were not excluded only on the basis of low quality.

### Measures of treatment effect

#### Continuous data

Continuous outcomes (for example weight loss measure by weight) were expressed, if possible, as weighted mean differences with 95% confidence intervals (CI). If results for continuous outcomes were presented on different scales, we planned to use the standardised mean differences (SMD).

#### Dichotomous data

Dichotomous outcomes (for example stroke yes or no) were expressed as odds ratios (OR) or relative risks (RR) with 95% CI.

#### Time-to-event data

Time-to-event outcomes (for example time until death) were expressed as hazard ratios (HR) with 95% CI.

### Unit of analysis issues

Different units of analysis (for example OR and RR) were planned to be subjected to a sensitivity analysis.

### Dealing with missing data

When necessary, relevant missing data were sought by correspondence with the main authors of the studies. Evaluation of important numerical data such as screened, eligible and randomised patients as well as intention-to-treat and per-protocol population were carefully performed. Drop-outs, misses to follow-up and withdrawn study participants were investigated.

### Dealing with duplicate publications

Multiple publications were planned to be collated and assessed as one study to try maximise yield of information by simultaneous evaluation of all available data.

### Assessment of heterogeneity

Heterogeneity between trial results were tested for using a standard chi-squared test. Tests of heterogeneity are used for examining whether the observed variation in study results is compatible with the variation expected by chance alone. A significance level of alpha set at 0.1 was used for the test of heterogeneity in view of the low power of such tests. Heterogeneity was also examined with  $I^2$ , where  $I^2$  values of 50% and more indicate a substantial level of heterogeneity ([Higgins 2003](#)). When found, we attempted to determine potential reasons for it by examining individual study characteristics and those of subgroups of the main body of evidence.

### Assessment of reporting biases

Funnel plot asymmetry were planned to be assessed statistically to explore publication bias if sufficient randomised clinical trials were identified (Egger 1997).

### Data synthesis

Data were summarised statistically if they were available, sufficiently similar and of sufficient quality. Statistical analyses were performed according to the statistical guidelines referenced in the newest version of the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2005). Pooled results were analysed using primarily a fixed-effect model.

### Subgroup analysis and investigation of heterogeneity

We planned to perform subgroup analyses to explore whether there were any systematic differences between groups of patients. If the results of at least one of the main outcomes were significant, in order to explore effect size differences and if the amount of data permitted, subgroup analyses were planned to be conducted according to the following:

- Weight level (BMI) at baseline;
- Age;
- Gender;
- Different comparison interventions;
- Duration of intervention.

### Sensitivity analysis

We performed sensitivity analyses to explore the influence of the following factors on effect size:

- repeating the analysis excluding unpublished studies;
- repeating the analysis taking study quality, as specified above, into account;
- repeating the analysis excluding any very long or large studies to establish how much they dominate the results.
- repeating the analysis excluding studies using the following filters: diagnostic criteria, language of publication, source of funding (industry versus other), country.

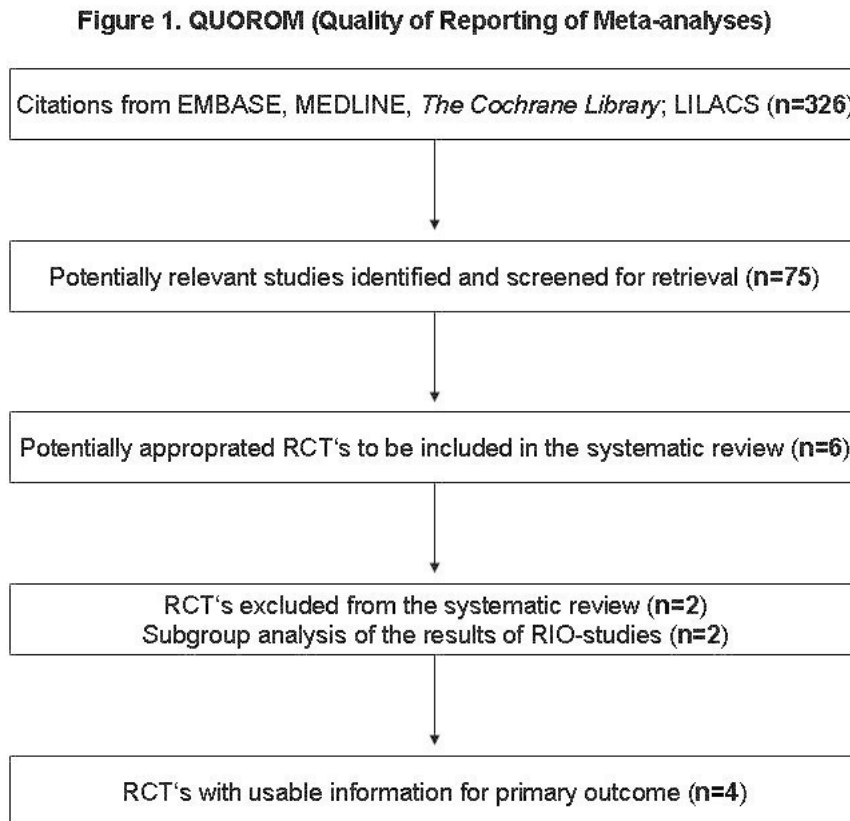

The robustness of the results was also be tested by repeating the analysis using different measures of effects size (risk difference, odds ratio etc) and different statistical models (fixed and random-effects models).

## RESULTS

### Description of studies

From the initial search, 326 records were identified, and from these, 75 full papers were identified for further examination. The other studies were excluded on the basis of their abstracts because they were not relevant to the question under study. See [Figure 1](#) for details of the amended QUOROM (quality of reporting of meta-analyses) statement.

**Figure 1. QUOROM (quality of reporting of meta-analyses) flow chart for study selection**

After screening the full text of the selected papers, six studies finally met the inclusion criteria. Two studies were only presented as abstracts of congresses. One of these was a subgroup analysis of the RIO-studies and it was not included in the results. This study is included in [Characteristics of excluded studies](#). One of the six studies is an ongoing trial, with an expected end of study in August, 2007 (see [Characteristics of ongoing studies](#) for details). One additional title was selected, but it was not retrieved because the reference was wrong. The other three articles were published in peer review journals.

**Assessment of publication bias and inter-rater agreement**

Two authors (CC and CA) reviewed the studies. There was agreement on the studies to be extracted for closer inspection from the searches. The full papers were obtained, and from these, the studies eligible for the review were selected. The authors completely agreed on the final papers chosen for the review.

**Missing data**

Some authors were contacted for further information. The authors of the [RIO-North America](#) study (Dr Pi-Sunyer and Dr Aronne) were contacted by e-mail to ask whether they could send details about the results, which were only published as placebo subtracted changes from baseline or changes from baseline only presented in figures, but unfortunately we received no answer. Professor

Hollander, who presented the results of the [RIO-Diabetes](#) trial in the '1st International Congress on "Prediabetes" and the Metabolic Syndrome, 2005', was contacted by e-mail for particulars about the methodology and results of the study, but also did not reply. Dr Jensen was contacted by e-mail to ask about more information regarding the study entitled "The selective CB1-receptor antagonist rimonabant reduces body weight and waist circumference in obese subjects" which was presented only as an abstract. He replied, and stated that the presented study constituted a subgroup analysis of the results of three RIO-studies ([RIO-Europe](#), [RIO-Lipids](#) and [RIO-North America](#)); the abstract publication therefore was not included in the present analysis. With regards to the selected title where the reference was wrong entitled "SR141716, a selective cannabinoid CB1 receptor antagonist, reduces hunger, caloric intake and body weight in over weight or obese men", we got an answer from Dr Belisse, one of authors, informing that the study was part of a series of trials done by the Sanofi company on this product, and that the methods and results are the property of Sanofi. Unfortunately, we got no answer from Sanofi when we asked for unpublished data.

**Excluded studies**

Excluded studies and the reasons for exclusion are given in the table [Characteristics of excluded studies](#).

## Included studies

Details of the characteristics of the included studies are given in the table [Characteristics of included studies](#). The following gives a brief overview.

### Characteristics of included studies

#### Methods

All four studies finally selected for the review were randomised controlled trials published in English. The duration of the intervention was 24 months for the [RIO-North America](#) and 12 months for the [RIO-Diabetes](#), [RIO-Lipids](#) and [RIO-Europe](#) study. Although the last two described a period of 24 months during which they were conducted, only the first 12-months results are provided. All trials had a run-in, as a single blind period before the randomisation.

#### Participants

The included studies involved 6625 participants. The main inclusion criteria entailed adults (18 years or older), with a body mass index greater than 27 kg/m<sup>2</sup> and less than 5 kg variation in body weight within the three months before study entry.

#### Intervention

All trials were multicentric. The [RIO-North America](#) was conducted in the USA and Canada, [RIO-Europe](#) in Europe and the USA, [RIO-Diabetes](#) in the USA and 10 other different countries not specified, and [RIO-Lipids](#) in eight unspecified different countries. The intervention received was placebo, 5 mg of rimonabant or 20 mg of rimonabant once daily in addition to a mild hypocaloric diet (600 kcal/day deficit).

#### Outcomes

##### Primary

In all studies the primary outcome assessed was weight change from baseline after one year of treatment and the [RIO-North America](#) study also evaluated the prevention of weight regain between the first and second year. All studies evaluated adverse effects, including those of any kind and serious events. Quality of life was measured in only one study, but the results were not described ([RIO-Europe](#)).

##### Secondary and additional outcomes

These included prevalence of metabolic syndrome after one year and change in cardiometabolic risk factors such as blood pressure, lipid profile, etc.

No study included mortality and costs as outcome.

The timing of outcome measures was variable and could include monthly investigations, evaluations every three months or a single final evaluation after one year.

#### Risk of bias in included studies

The methodological characteristics of the included studies are summarised in [Table 1](#). There was complete agreement between the two authors regarding quality assessment; therefore a kappa-statistic was not calculated.

## Overview

All four studies had some methodological weaknesses according to the methodological quality criteria evaluated. None fulfilled all quality criteria.

### Randomisation and allocation concealment

All selected trials were described as randomised. However, only two studies reported an appropriate method of randomisation ([RIO-Europe](#) and [RIO-North America](#)). Most studies did not mention any procedure for allocation concealment, with only one reporting adequate allocation concealment ([RIO-Europe](#)). The main characteristics of the participants in the three groups were similar at baseline in all selected studies.

### Blinding

The selected trials were described as double-blind. However, no details of the methods employed or at which stage of the process blinding was performed, were reported. No trial reported blinding of outcome assessors (those taking samples or carrying out laboratory tests). None of the included studies specifically reported blinding of either the study participants or the providers of treatment.

### Power calculation

Power calculations were reported as incorporated in the design of one of the four studies included in this review. The sample size of the [RIO-North America](#) study was based on 99% power to detect a 3-kg difference between one dose of rimonabant and placebo after one year with  $P < 0.025$ . No other included study reported power calculations.

### Descriptions of losses to follow-up

Three of the selected trials described losses to follow-up ([RIO-Europe](#), [RIO-Lipids](#) and [RIO-North America](#)). Only one, [RIO-Diabetes](#), described the number of patients who discontinued treatment because of adverse events.

### Intent-to-treat (ITT) population analyses

All studies reported an intention-to-treat analysis. The method used for missing data was mainly last-observation-carried-forward. No study described the ITT population in detail.

### Effects of interventions

Results of the meta-analyses are reported below. Data from the studies were pooled for meta-analysis at one year.

#### Primary outcomes

##### Weight (kg) change

Comparing rimonabant 20 mg with placebo, meta-analysis of all included studies showed evidence of heterogeneity with a reduction in mean weight of 4.6 kg for the rimonabant group but this result could not be considered ( $I^2 = 60.6\%$ ). When we performed the analysis excluding the [RIO-Diabetes](#) study which was only published as an abstract of congress we observed that the heterogeneity was significantly reduced and the pooled data showed a reduction in mean weight of 4.9 kg (-4.9 weighted mean difference [WMD], 95% confidence interval [CI] -5.3 to -4.5). In the comparison between rimonabant 5 mg and placebo, the pooled

effect was a weight reduction of 1.3 kg for the rimonabant group excluding the [RIO-North America](#) study due to lack of data (-1.3 kg WMD, 95% CI -1.6 to -0.9). Comparing the two intervention groups, there was a pooled effect of weight reduction of 3.3 kg for the rimonabant 20 mg group, also excluding the [RIO-North America](#) study (-3.3 kg WMD, 95% CI -3.7 to -2.9). All results were statistically significant ( $P < 0.0001$ ).

#### **Waist circumference (cm) change**

The pooled meta-analysis of all included studies showed evidence of a reduction in waist circumference of 3.8 cm for the rimonabant 20 mg group when compared with placebo (-3.8 cm WMD, 95% CI -4.3 to -3.4). In the rimonabant 5 mg versus placebo comparison, the pooled effect was a reduction of 1.2 cm for the rimonabant group excluding the [RIO-North America](#) study due to lack of data (-1.2 cm WMD, 95% CI -1.7 to -0.7). Comparing the two intervention groups, the pooled data showed substantial heterogeneity ( $I^2 = 53.5\%$ ). We performed several sensitivity analysis, but even excluding the [RIO-Diabetes](#) study which was only published as an abstract of congress, we could not explain the observed heterogeneity. For this reason the pooled data are not reliable. All results were statistically significant ( $P < 0.0001$ ).

#### **Adverse effects (general)**

The combined results of the three trials (excluding the [RIO-Lipids](#) study) indicated that compared to placebo, patients treated with rimonabant 20 mg reported significantly more general adverse effects: RR = 1.05, 95% CI 1.01 to 1.08 ( $P = 0.005$ ). There were no statistically significant differences for adverse effects in the meta-analysis comparing the results of rimonabant 5 mg with placebo (also excluding the [RIO-Lipids](#) study). Comparing the two intervention groups, patients treated with rimonabant 20 mg reported significantly more adverse effects than the rimonabant 5 mg group: RR = 1.04, 95% CI 1.01 to 1.06 ( $P = 0.008$ ). The [RIO-Lipids](#) study was not included because it did not provide overall numbers for adverse effects but for single events only (multiple episodes were possible for each patient).

#### **Adverse effects (serious)**

The pooled meta-analysis of all included studies showed that compared to placebo, patients treated with rimonabant 20 mg reported significantly more serious adverse effects: RR = 1.37, 95% CI 1.04 to 1.80 ( $P = 0.03$ ). There were no statistically significant differences for serious adverse effects in the meta-analysis comparing the results of rimonabant 5 mg with placebo and also for the comparison between the two intervention groups.

#### **Discontinuation due to adverse effects**

The pooled meta-analysis of all included studies showed that compared to placebo, patients treated with rimonabant 20 mg reported a significantly greater rate of discontinuation due to adverse effects: RR = 1.92, 95% CI 1.57 to 2.34 ( $P < 0.00001$ ). There were no statistically significant differences comparing the results of rimonabant 5 mg with placebo. For the comparison between the two intervention groups patients treated with rimonabant 20 mg also reported a significantly greater rate of discontinuation due to adverse effects: RR = 1.58, 95% CI 1.34 to 1.85 ( $P < 0.00001$ ).

## **Secondary outcomes**

### **Blood pressure change**

Comparing rimonabant 20 mg with placebo, the meta-analysis of the included studies, excluding the [RIO-North America](#) study due to lack of data, showed evidence of an average reduction in systolic and diastolic blood pressure of 2 mm Hg (-2 mm Hg WMD, 95% CI -3 to -1) and 1 mm Hg (-1 mm Hg WMD, 95% CI -2 to -0.5) respectively in the rimonabant group. There were no statistically significant differences for the rimonabant 5 mg versus placebo comparison in the same three studies, considering both systolic and diastolic blood pressures.

Comparing the two intervention groups, the pooled data showed substantial heterogeneity ( $I^2 = 55.6\%$ ). We performed sensitivity analyses, but even excluding the [RIO-Diabetes](#) study which was only published as an abstract of congress, we could not explain the observed heterogeneity. For this reason the pooled data are not reliable.

### **Lipid profile change**

Serum triglyceride levels were reported in all studies as well as high density lipoprotein cholesterol and a meta-analysis of these data was carried out.

The pooled data of the all studies showed a significant lowering of plasma triglycerides in the rimonabant 20 mg group compared with placebo of 19.8 mg/dl (-19.8 mg/dl WMD, 95% CI -24.1 to -15.6;  $P < 0.00001$ ). There was no statistically significant reduction of plasma triglycerides in the rimonabant 5 mg and placebo comparison in three studies (excluding the [RIO-North America](#) study due to lack of data). In the rimonabant 20 mg versus 5 mg comparison the meta-analysis of same three studies showed a statistically significant average reduction of 19.9 mg/dl (-19.9 mg/dl WMD, 95% CI -25.4 to -14.4;  $P < 0.00001$ ) for the 20 mg group.

For the high density lipoprotein cholesterol analysis, the pooled data of all studies of the rimonabant 20 mg versus placebo comparison showed an increase of 3.5 mg/dl in the rimonabant group (3.5 mg/dl WMD, 95% CI 3.0 to 4.0). For the rimonabant 5 mg versus placebo comparison, excluding the [RIO-North America](#) study, there was an increase of 1.3 mg/dl in the rimonabant group (1.3 mg/dl WMD, 95% CI 0.3 to 1.9). Comparing the two intervention groups, an average increase of 2.3 mg/dl (2.3 mg/dl WMD, 95% CI 1.7 to 3.0) was found favouring the rimonabant group. All analyses were statistically significant ( $P < 0.00001$ ).

### **Health-related quality of life**

This was measured in only one study, but the results were not described ([RIO-Europe](#)).

### **Mortality and costs**

No study evaluated mortality or costs as an outcome. The [RIO-Lipids](#) study described in the results section that there were no deaths in any of the three groups. The [RIO-Europe](#) study mentioned in the results section that two deaths occurred, one in the placebo group (haemorrhagic cerebrovascular accident, about 2.5 months after randomisation) and one in the rimonabant 20 mg group (uterine adenocarcinoma, two months after randomisation). The other two studies did not describe mortality.

### Heterogeneity

Statistical tests for heterogeneity yielded statistically significant results in weight change in the rimonabant 20 mg with placebo comparison, waist circumference change in the rimonabant 20 mg with rimonabant 5 mg comparison and in diastolic blood pressure comparing the two intervention groups. In general, the studies seemed to be homogeneous, but one of them ([RIO-Diabetes](#)) was only published as an abstract of congress. This possible source for heterogeneity was investigated in the sensitivity analyses and is described below.

### Subgroup analyses

We did not have sufficient data to perform subgroup analyses for initial level of weight, age, sex or duration of treatment.

### Sensitivity analyses

Since we observed statistical heterogeneity for some pooled estimates, we performed several sensitivity analyses. Excluding the [RIO-Diabetes](#) study, the only trial which was not published in a peer review journal, appeared to significantly reduce the observed heterogeneity in the weight change outcome for the rimonabant 20 mg versus rimonabant 5 mg comparison. In the other two results with substantial heterogeneity (waist circumference change and diastolic blood pressure change in the rimonabant 20 mg versus rimonabant 5 mg comparison), even excluding the same study could not relevantly reduce heterogeneity. The studies appeared to be similar, but exploring the influence of other factors on effect size did not seem to be appropriate.

### Assessment of publication bias

Funnel plots were not carried out due to the small number of included studies.

## DISCUSSION

### Summary of main results

In this systematic review, we found a statistically significant effect of rimonabant on body weight, blood pressure and plasma lipids. Compared with placebo, rimonabant 20 mg produced a 4.9 kg greater reduction in body weight in trials with one-year results. Improvements in waist circumference, high-density lipoprotein cholesterol, triglyceride levels and systolic and diastolic blood pressure also were seen with rimonabant 20 mg. However, the results with rimonabant 5 mg were not the same, and even being statistically significant the weight reduction was only 1.3 kg greater when compared with placebo. No clinically relevant effects on plasma lipids and blood pressure were found with 5 mg. Comparing the two interventions groups the results were similar to the rimonabant 20 mg versus placebo comparison, favouring the first group. Rimonabant 20 mg caused significant more adverse effects both of general and serious type, especially of nervous system, psychiatric or gastro-intestinal origin.

Although the studies were large trials, we detected deficiencies in the methodological quality of all included studies in this review. Methods for concealment of allocation were described in only one study, and the randomisation method was described in only two. Most studies were described as double-blind, but it was unclear which two parties were blinded (patient, treatment administrator or outcome assessor). In spite of the reported deficiencies in the methodological quality, the data were too homogeneous to explore

the effects of allocation concealment and blinding on outcomes. Only one study described power calculation, and in the intention-to-treat (ITT) analysis part, no study described the ITT population. The quality of descriptive information on study population and the intervention were generally adequate.

### Potential biases in the review process

This is the first systematic review and meta-analysis on the topic of rimonabant related to overweight and obesity. It offers an up-to-date and complete overview of all randomised trials concerning the topic as it is based on an extensive search, including unpublished studies. In addition, strong efforts have been done to minimise missing or incomplete data by attempting to contact all authors.

Even if this review presents a possibly confusing amount of data and figures, completeness is one of the strengths of a Cochrane systematic review. The way we presented these data, subdivided in subheadings in different tables, makes it possible for the reader to find every specific piece of information obtained from the individuals trials.

This review will be regularly updated, allowing eventual addition of information or correction of possible errors.

The major methodological limitation of this review is attributed to the quality of the included studies. We observed a high attrition rate in both treatment and placebo groups (approximately 40% in all studies). Authors tried to address this by carrying forward the last observation on record to the end of the study. When the data are analysed in this way, biased results may occur in either direction, depending on the reasons for withdrawal and the differential dropout rates in treatment and placebo groups. If we consider, for example, that patients in the placebo group may drop out of the study early because of weight gain due to lack of efficacy, measuring their weight at the point of withdrawal will likely underestimate their weight at the end of the study period supposing that they should slowly gain weight during the rest of the intervention period. This would underestimate the degree of weight gain in the placebo group and suggest a falsely lower overall treatment effect. On the other hand, if non-responders in the treatment arm drop out early leaving only responders to complete the trial, the treatment effect may be overestimated. Such high attrition rates are difficult to compensate by any form of analysis. Considerable bias may be introduced into the results of these studies, and should be kept in mind when interpreting the results of this review.

The [RIO-North America](#) study reported outcomes in a way that could not contribute to meta-analyses. This problem was not solved by asking authors for additional data, because unfortunately we got no answer.

Research funded by pharmaceutical companies could be more likely to produce results favouring the tested drug. Consistent evidence also demonstrated that industry ties are associated with both publication delays and data withholding. These restrictions serve to compound bias in biomedical research. Rather, such behaviour appears to arise when investigators are involved in the process of bringing their research results to market ([Bekelman 2003](#)). In this review all studies were sponsored by the pharmaceutical company, in which the sponsor was the producer of the evaluated drug. The results should be interpreted with caution since conflict of interests could have influence on the results.

Health related quality of life is an important question that was not considered in the included studies. The effect of treatment on

patient-reported outcomes, including any report coming directly from affected persons concerning their life, health conditions and treatment should be considered in clinical trials.

Despite a thorough search, including requests to manufacturers, we still cannot rule out publication bias. The included studies are phase III clinical trials evaluating the effects, tolerability and safety of rimonabant. Others studies have probably been done primarily to evaluate the short-term effects of the drug, as indicated by one of the authors contacted. We tried to obtain unpublished studies from the manufacturer, but unfortunately got no answer. Still, we welcome unpublished data for future updates.

### Agreements and disagreements with other studies or reviews

Although this is the first systematic review concerning rimonabant in overweight and obesity, some reviews have been published recently (Boyd 2005; Cox 2005; Gelfand 2006; Tonstad 2006). They only focused on describing the clinical results in the published studies. The quality of these reviews is limited: selection criteria for the studies were insufficiently specified and there was no mentioning of the criteria used to assess the validity of individual trials. Further, these reviews did not present explicit methods on data extraction, assessment of quality or heterogeneity analyses.

Presently the approved anti-obesity pharmacotherapy options are limited to orlistat and sibutramine. Padwall (Padwall 2003) carried out a systematic review and meta-analysis of long term pharmacotherapy for overweight and obesity. Compared with placebo, those receiving orlistat had a 2.7 kg decrease in body weight, and the treatment with sibutramine produced a weight loss of 4.3 kg. Orlistat-treated patients displayed improvements in total cholesterol, low-density lipoprotein cholesterol, blood pressure, and glycaemic control but had increased rates of gastrointestinal side effects and slightly lower high-density lipoprotein levels. Sibutramine produced small improvements in high-density lipoprotein cholesterol and triglyceride levels, but was associated with a net increase in blood pressure.

Comparing the results obtained in this review with the results of the review evaluating the other two cited drugs it seems that the weight loss associated with rimonabant use was slightly greater compared to that related to sibutramine use, with more positive impact on cardiometabolic risk factors. The effects compared with orlistat seem to be greater weight loss and less frequent adverse effects. However, in the rimonabant studies the number of discontinuation due to adverse effects was greater when compared with orlistat studies. The authors of the rimonabant studies cited that the adverse effects were transient, based on the occurrence in the first months of the study. Although the number of patients discontinuing therapy due to adverse effects was approximately 10% in all studies, high study attrition rates raise the possibility that some of these events remained uncaptured.

Considering the figures presented in all studies related to weight loss change during the entire period, the pattern of weight loss observed indicated that approximately after the 36th week, the level of weight loss decreased and the body weight was maintained practically until the end of the studies. The [RIO-North America](#) evaluated the data after two years, and the patients who remained on rimonabant 20 mg seemed to maintain their weight loss, while those who were re-randomised to placebo gained significant weight. Since only the [RIO-North America](#) study reported results after two years where the patients were re-randomised after the end of the first year, and the results were only presented as placebo

subtracted changes from baseline, we did not include the data of the second year.

Both the American Food and Drugs Administration (FDA) and the European Agency for the Evaluation of Medicinal Products (EMA) demand that any anti-obesity drug should produce significantly greater weight loss compared to placebo. The FDA specifically demands that placebo-subtracted weight loss is at least 5%. Moreover, significantly more individuals in the drug treated group should lose 5% or more of their initial body weight compared to placebo. On the other hand, the EMA demands a weight loss of at least 10% from baseline, which should also be greater than placebo. The secondary outcome of anti-obesity drug trials is to ensure that this weight loss is sustained and able to induce a significant reduction in risk factors for a number of obesity related co-morbidities. Moreover, drug induced weight loss should have a positive impact on health related quality of life.

## AUTHORS' CONCLUSIONS

### Implications for practice

This review suggests that the use of rimonabant after one year could produce a modest weight loss of approximately 5%. Even modest amounts of weight loss may be potentially beneficial. Some caution regarding the observed results should be taken into account since the studies presented some deficiencies in the methodological quality. Studies with longer follow-up after the end of treatment and with more rigor in the quality of methodology should be done before definitive recommendations can be made regarding the role of this medication in the management of obese patients.

Drug therapy in obesity should always be considered in connection with non-pharmacological interventions, on an individual basis, with stronger consideration given to those individuals with greater degrees of obesity and associated co-morbidities. Efforts focusing on the prevention of obesity in non-obese people and non-pharmacological management in obese people should remain the cornerstone of obesity therapy. With regard to adverse effects, rimonabant is contraindicated for patients with severe depression and/or patients who are treated with antidepressive medications in Europe. Rimonabant is furthermore not recommended for patients with other untreated psychiatric conditions.

### Implications for research

Further high quality research is needed to assess the efficacy and safety of rimonabant over longer follow-up periods. Future adequately-powered trials should incorporate appropriate design principles including methods of allocation concealment, randomisation, blinding, minimization of attrition and follow-up of drop-outs. Whilst drop-outs and withdrawals can not always be avoided, every effort should be made to ascertain the reasons for withdrawals so that factors affecting adherence can be further elucidated. Future studies should evaluate the use of medication associated with exercise and behavioural modification, identify subgroups of patients that may derive greater benefit from drug therapy, incorporate health-related quality outcomes and also assess the economic costs of treatment.

## CHARACTERISTICS OF STUDIES

### Characteristics of included studies [ordered by study ID]

#### RIO-Diabetes

Methods	DURATION OF INTERVENTION: 12 months
	DURATION OF FOLLOW-UP: 0 months
	RUN-IN PERIOD: 1- ?
	LANGUAGE OF PUBLICATION: English
Participants	WHO PARTICIPATED:
	INCLUSION CRITERIA: Age: 18 to 70 years old;

#### Rimonabant for overweight or obesity (Review)

**RIO-Diabetes** (Continued)

BMI of 27 to 40 kg/m<sup>2</sup>;  
type 2 diabetes that had been treated with metformin or various sulfonylurea monotherapy for at least 6 months.  
hgA1c between 6.5% and 10%, fasting plasma glucose between 100 mg/dL and 271 mg/dL,  
variation in body weight within the previous three months < 5kg

EXCLUSION CRITERIA: ?

Interventions	<p>NUMBER OF STUDY CENTRES: 151</p> <p>COUNTRY/LOCATION: USA and 10 other countries (?)</p> <p>SETTING: ?</p> <p>INTERVENTION (ROUTE, TOTAL DOSE/DAY, FREQUENCY): Placebo or rimonabant 20 mg or rimonabant 5 mg - daily in addition to a hypocaloric diet</p>
Outcomes	<p>PRIMARY: weight change in 1 year</p> <p>SECONDARY: change in hgA1c, waist circumference, fasting lipid levels with emphasis on HDL and TG, and change in metabolic syndrome prevalence as defined by the ATP III criteria.</p> <p>TIMING OF OUTCOME MEASURES: body weigh, BP, waist circumference - monthly, the other measures every 3 months</p> <p>ALL-CAUSE MORTALITY. 0</p> <p>DISEASE SPECIFIC MORTALITY: 0</p> <p>MORBIDITY/COMPLICATIONS: 1</p> <p>QUALITY OF LIFE: 0</p> <p>ADVERSE EFFECTS: 1</p> <p>COSTS: 0</p>

**RIO-Lipids** (Continued)

Placebo or rimonabant 20 mg or rimonabant 5 mg - daily in addition to a hypocaloric diet

Outcomes

PRIMARY:  
weight change

SECONDARY:  
changes in HDL, TG, Glucose and insulin during an oral glucose-tolerance test and the prevalence of metabolic syndrom

ADDITIONAL:  
waist circumference, leptin and adiponectin levels and relevant biochemical cardiovascular markers

TIMING OF OUTCOME MEASURES:  
body weigh, BP, waist circumference - monthly, the other measures only 12 months

ALL-CAUSE MORTALITY.  
0

DISEASE SPECIFIC MORTALITY:  
0

MORBIDITY/COMPLICATIONS:

English

Participants

WHO PARTICIPATED:

INCLUSION CRITERIA:  
18 years or older;  
BMI of 30 or 27 with treated or untreated dyslipidemia or hypertension

**RIO-North America** (Continued)

**EXCLUSION CRITERIA:**

weight fluctuation of more than 5 Kg in the previous 3 months; clinically significant cardiac, renal, hepatic, gastrointestinal tract, neuropsychiatric or endocrine disorders, drug-treated or diagnosed type 1 or 2 diabetes, use of medications that alter body weight or appetite, a history of current substance abuse; changes in smoking habits or smoking cessation within the past 6 months

**DIAGNOSTIC CRITERIA:**

Interventions	<p><b>NUMBER OF STUDY CENTRES:</b> 72 (64 - USA and 8 - Canada)</p> <p><b>COUNTRY/LOCATION:</b> USA and Canada</p> <p><b>SETTING:</b></p> <p><b>INTERVENTION (ROUTE, TOTAL DOSE/DAY, FREQUENCY):</b> Placebo or rimonabant 20 mg or rimonabant 5 mg - once/day in addition to a hypocaloric diet and stimulus for exercising</p>
Outcomes	<p><b>PRIMARY:</b> weight change in 1 year prevention of weight regain between the first and second years</p> <p><b>SECONDARY:</b> changes in HDL in 1 year and the prevalence of metabolic syndrome</p> <p><b>ADDITIONAL:</b> changes in BP, levels of glucose and insulin, lipids, and insulin resistance</p> <p><b>TIMING OF OUTCOME MEASURES:</b> in the end of year 1 and 2</p> <p><b>ALL-CAUSE MORTALITY:</b> 0</p> <p><b>DISEASE SPECIFIC MORTALITY:</b> 0</p> <p><b>MORBIDITY/COMPLICATIONS:</b> 1</p> <p><b>QUALITY OF LIFE:</b> 0</p> <p><b>ADVERSE EFFECTS:</b> 1</p> <p><b>COSTS:</b> 0</p>

Notes

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Allocation concealment?	Unclear risk	B - Unclear

BMI - body mass index; hgA1c - hemoglobinaA1c; HDL - high density lipoprotein; TG - triglycerides; BP - blood pressure; LDL - low density lipoprotein; chol/HDL - ratio total cholesterol / HDL; VLCD - very low calory diet

**Characteristics of excluded studies** [ordered by study ID]

Study	Reason for exclusion
Jensen 2004	Subgroup analysis of the results of the RIO-studies

**Characteristics of ongoing studies** [ordered by study ID]

**STRADIVARIUS**

Trial name or title	STRADIVARIUS (Strategy To Reduce Atherosclerosis Development InVolving Administration of Rimonabant - the Intravascular Ultrasound Study)
Methods	
Participants	<p>Ages Eligible for Study: 18 Years and above, Genders Eligible for Study: Both</p> <p>Criteria</p> <p>Inclusion Criteria:</p> <p>Written and signed informed consent</p> <p>Indication for coronary angiography</p> <p>Abdominal obesity defined by waist circumference &gt; 88 cm in women or &gt; 102 cm in men</p> <p>At least one of the two following conditions: *a) Metabolic syndrome as defined by the presence of at least two of the following additional risk factors: 1. Triglyceride level <math>\geq</math> 150 mg/dL (1.69 mmol/L); 2. HDL cholesterol &lt; 40 mg/dL (1.03 mmol/L) [men] or 50 mg/dL (1.28 mmol/L) [women]; 3. Fasting glucose <math>\geq</math> 110 mg/dL (6.1 mmol/L); 4. High blood pressure (<math>\geq</math> 140 mmHg systolic and/or <math>\geq</math> 90 mmHg diastolic) at Screening visit, or current treatment by anti-hypertensive medication; *b) Currently smoking (&gt; 10 cigarettes /day) and willing to stop</p> <p>Angiographic evidence of coronary heart disease as defined by at least 1 lesion in a native coronary artery that has <math>\geq</math> 20% reduction in lumen diameter by angiographic visual estimation</p> <p>Presence of at least one coronary artery complying with the definition of "target vessel" for IVUS assessment</p> <p>Acceptation of the Baseline IVUS tape by the IVUS Core Laboratory</p> <p>Exclusion Criteria:</p> <p>Age &lt; 18 years</p> <p>Pregnant or breast-feeding women</p> <p>History of very low-calorie diet or surgical procedures for weight loss (eg, stomach stapling, bypass) within 6 months prior to screening visit</p> <p>Obesity of known endocrine origin</p> <p>Uncontrolled diabetes with HBA1c &gt;10%</p> <p>Presence of any severe medical or psychological condition, that in the opinion of the Investigator would compromise the subject's safety or successful participation in the study</p> <p>Severe congestive heart failure (New York Heart Association [NYHA] Class III or IV)</p> <p>Clinically significant heart disease which in the opinion of the Investigator is likely to require coronary artery bypass graft (CABG), percutaneous coronary intervention (PCI), cardiac transplantation, surgical repair and/or replacement during the course of the study</p> <p>Angioplasty of a non-qualifying artery which is considered at high risk of acute complication or restenosis, during baseline catheterization</p> <p>&gt;50% reduction in lumen diameter of the left main coronary artery by visual angiographic estimation</p> <p>Recent ST-elevation myocardial infarction (MI) <math>\leq</math> 72 hours prior to randomization</p>
Interventions	<p>Study Type: Interventional</p> <p>Study Design: Treatment, Randomized, Double-Blind, Placebo Control, Parallel Assignment, Safety/Efficacy Study</p>

**STRADIVARIUS** (Continued)

Outcomes	Inhibition of Atherosclerosis Progression Assessed by IVUS (IntraVascular UltraSounds)
Starting date	Study start: January 2005; Study completion: August 2007
Contact information	Sponsored by: Sanofi-Aventis Information provided by: Sanofi-Aventis ClinicalTrials.gov Identifier: NCT00124332
Notes	Data from "www.clinicaltrials.gov"  The purpose of this study is to determine if rimonabant 20 mg once daily (od) administered during 18-20 months will reduce progression of coronary atherosclerosis as assessed by intravascular ultrasound (IVUS) when administered on top of standard behavioral and pharmacological therapy given as needed, in patients with abdominal obesity associated with current smoking and/or metabolic syndrome.  Study ID Numbers: EFC5827; SR141716  Location Information - Ohio: The Cleveland Clinic Foundation, Cleveland, Ohio, 44195, United States  This study is no longer recruiting patients.

**DATA AND ANALYSES**
**Comparison 1. Rimonabant 20 mg vs placebo (after one year)**

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Weight [kg] change	4	4105	Mean Difference (IV, Fixed, 95% CI)	-4.64 [-4.99, -4.28]
2 Waist circumference [cm] change	4	4105	Mean Difference (IV, Fixed, 95% CI)	-3.84 [-4.26, -3.42]
3 Adverse effects (general)	3	3417	Risk Ratio (M-H, Fixed, 95% CI)	1.05 [1.01, 1.08]
4 Adverse effects (serious)	4	4105	Risk Ratio (M-H, Fixed, 95% CI)	1.37 [1.04, 1.80]
5 Systolic blood pressure [mmHg] change	3	2279	Mean Difference (IV, Fixed, 95% CI)	-1.57 [-2.59, -0.55]
6 Diastolic blood pressure [mmHg] change	3	2279	Mean Difference (IV, Fixed, 95% CI)	-1.16 [-1.86, -0.47]
7 Triglycerides levels [mg/dl] change	4	4105	Mean Difference (IV, Fixed, 95% CI)	-19.82 [-24.10, -15.55]
8 High-density lipoprotein [mg/dl] change	4	4105	Mean Difference (IV, Fixed, 95% CI)	3.51 [2.99, 4.04]
9 Discontinuation due to adverse events	4	4105	Risk Ratio (M-H, Fixed, 95% CI)	1.92 [1.57, 2.34]

## WHAT'S NEW

Date	Event	Description
4 October 2008	Amended	Converted to new review format.

## CONTRIBUTIONS OF AUTHORS

CINTIA CURIONI: Protocol and review development, searching for trials, selection of studies, quality assessment, data extraction, data analysis, review development.

CHARLES ANDRÉ: Selection of studies, quality assessment, data extraction, data analysis, review development.

## DECLARATIONS OF INTEREST

None known

## SOURCES OF SUPPORT

### Internal sources

- Instituto de Medicina Social - UERJ, Brazil.
- Universidade Federal do Rio de Janeiro, Brazil.

### External sources

- FAPERJ, Brazil.

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

In the protocol quality assessment according to the criteria by Schulz and Jadad were planned. We did not pursue bias categorisation but preferred an individual component analysis approach instead.

---

**NOTES**

On October 23rd 2008 the European Medicines Agency (EMA) recommended the suspension of the marketing authorisation for rimonabant from the manufacturer. The EMA concluded that the benefits of rimonabant no longer outweigh its risk and the marketing authorisation should be suspended across the European Union.
