Chiral ionic liquids supported on natural sporopollenin microcapsules†

Ivan Palazzo,^a Andrea Mezzetta,^a Lorenzo Guazzelli,^{ID}*^a Stefania Sartini,^a Christian Silvio Pomelli,^a Wallace O. Parker Jr^b and Cinzia Chiappe^{ID}*^a

Supported chiral ionic liquids (SILs) were prepared choosing the starting material for the ionic liquid part from the enantiopure stock of the chiral pool (monoterpenoids and an amino acid) and the sporopollenin as an environmentally friendly support. Sporopollenins are microcapsules with naturally well-defined sizes and shapes that can be obtained from pollen grains after removal of the internal cytoplasm and the second shell layer. As thermally stable organic biocompatible structures, sporopollenins have attracted increasing interest in recent years for several applications. Herein, bio-based ILs were anchored onto the surface of sporopollenins obtained from the pollen of *Populus deltoides*, selected as a model pollen grain. These new structures, which present an external positively charged shell, were characterized by physico-chemical techniques (ATR-FTIR, TGA, SEM, EDX, and solid-state ¹³C NMR). A metathesis reaction was also performed on selected bio-based IL modified sporopollenins, demonstrating the possibility to switch the surface properties by exploiting well-known IL chemistry.

Introduction

In the last two decades, ionic liquids (ILs) have received increasing interest in the area of green chemistry,^{1,2} where they can play an important role as alternative environmentally friendlier media with unique solvent properties, including the peculiar ability to dissolve biopolymers,^{3,4} and/or as catalysts for several important reactions.^{5,6} However, in contrast to what was generally thought only 10 years ago, it is well-known that ILs also present some drawbacks that need to be addressed: ILs can be more toxic than molecular solvents, their cost is often higher than that of molecular solvents and they are generally based on petrol derived raw materials.^{7,8} Thus, recently, considerable attention has been directed toward the replacement of the most common IL constituent ions with bio-based materials^{9,10} which have higher biodegradability and unlimited availability from renewable resources. On the other hand, immobilization of ILs on suitable supports represent another strategy to reduce costs and increase sustainability. In organic catalytic reactions, supported ionic liquids (SILs) offer several advantages over free ILs, reducing the amount of used IL, avoiding its leaching, and improving the products recoverability and reusability of IL and catalysts.¹¹ Nonetheless, as novel functional materials in surface

science and material chemistry, SILs can modify and improve the properties of solids, modifying wettability, lubricating properties, separation efficiency and electrochemical response.¹² To date, zeolite-, silica-, carbon nanotube-, polystyrene- and cross-linked polymers represent the most used materials to obtain SILs. However, many of these IL supports possess some disadvantages: complicated preparation technologies and a high production costs are required, in particular, when empty size homogeneous systems with peculiar microscale and nanoscale architectures are mandatory. Thus, the possibility to have highly effective and cheap polymeric supports for the heterogeneous catalysts is highly desirable. Nature can provide a myriad of unique, widely available biological materials with surprising microscale and nanoscale architectures. One interesting natural alternative to synthetic organic polymers is represented by sporopollenin, a highly cross-linked polymer, which is the main component of outer shell of pollen grains and plant spores (exine).¹³ It is characterized by a remarkable chemical, physical and biological stability even at high temperatures, that arise from its high cross-linked structure involving tertiary carbons and ethers. Although it is still a matter of discussion,^{14–21} sporopollenin possesses aliphatic chains bound to aromatic moieties, conjugated phenols, aliphatic alcohols, lactones, and carboxylic acids. Morphologically, sporopollenin exine capsules (SEC) are microcapsules with a hydrophobic cavity and a variable number of pores, species specific in shape and size, with elaborated 3D surface architectures. SEC have been used to sequester edible oils from emulsions efficiently, encapsulate various polar and

† Electronic supplementary information (ESI) available. See DOI: 10.1039/c8ra03455a

nonpolar materials, and act as drug delivery systems with excellent enhanced bioavailability.^{22–27} On the other hand, the presence of functional groups on the outer surface allows for their further modification. Chemically modified SEC have been employed in water remediation studies,²⁸ as stationary phases chromatography,²⁹ and as solid supports for peptide synthesis,³⁰ enzyme immobilization,^{31,32} and chemical reactions.^{33,34} In the context of drug delivery, efficient drug encapsulation systems have also been prepared by coating SEC with natural biopolymer composites.^{35,36} Recently, sporopollenin has also been used in the area of biomass valorization. SEC surfaces have been modified by sulfonation, and the obtained material tested as a heterogeneous catalyst in the dehydration of D-xylose and xylan to produce furfural.³⁷

Despite its potentiality also the chemistry of SEC presents some drawbacks in term of sustainability. Extraction of SEC from the whole pollen grains and plant spores traditionally entails the use of harsh working protocols/conditions (*e.g.* acetic anhydride/sulfuric acid and heating,³⁸ HF,³⁹ 4-methylmorpholine *N*-oxide,⁴⁰ KOH/H₃PO₄ (ref. 41)). Moreover, these procedures, which are necessary to remove the internal cytoplasm and the second shell layer (intine), comprised mainly of cellulose, hemicellulose, and pectin, can determine significant modifications on the polymer composition and capsule shape, negatively affecting their use in a variety of the above mentioned applications.

However, an improvement to SEC extraction, in terms of time and environmental impact, has been proposed by Mundargi *et al.*⁴² and, more recently, the possibility to use ILs as extraction media has been demonstrated by Chiappe *et al.*, although the product was not fully characterized or explored as polymeric support.⁴³

Herein we show that sporopollenin microcapsules, purified using an IL, can be used to prepare, through grafting procedures, charged natural polymeric capsules. Despite the increasing number of studies aimed at using SEC as solid supports, surprisingly, these microcapsules have never been employed for the immobilization of ILs. The excellent stability and durability of the employed materials and the tunability of anchored ILs, which are also chiral, give the possibility to obtain new environmentally friendly functional materials with high potentialities for application in catalytic reactions, separation technologies and electrochemistry.

Results and discussion

Sporopollenin exine capsules (SEC) were isolated from defatted pollen of *Populus deltoides* using the recently reported extraction protocol based on acidic ILs.⁴³ Briefly, pollen grains were suspended in 1-(4-sulfobutyl)-3-methylimidazolium hydrogen sulfate, [HSO₃C₄mim][HSO₄], and heated to 160 °C for 90 minutes. The ATR-FTIR spectrum of the isolated SEC (Fig. 1) is in agreement with those reported previously. Comparison with the spectrum of the pristine pollen clearly shows the removal of the polysaccharide portion (absence of the strong C–O–C and C–OH stretching at 1047 cm⁻¹), of the protein component (absence of the amide II band at 1544 cm⁻¹), and of the lipid fraction (absence of signals at 1738 cm⁻¹ and 1408 cm⁻¹). These

Fig. 1 ATR-FTIR spectra of sporopollenin (SEC), 3-chloropropyl-functionalized sporopollenin CPS-SEC and IL-functionalized sporopollenins: 5b and 6b.

data confirm that the treatment with [HSO₃C₄mim][HSO₄] can be considered an adequate chemical protocol to eliminate all the undesired components, including also proteins that may cause potential allergic reactions. However, as previously observed,⁴³ the main peculiarity of the FTIR spectrum of these SEC was the presence of two peaks at 1183 cm⁻¹ and 1036 cm⁻¹, which are usually not detected. Such signals can be assigned to the O=S=O group stretching modes. In agreement, elemental analysis showed the presence of sulfur in isolated SEC which was confirmed also by the EDX analysis. Although, in principle, these bands could be related to the presence of residual IL, having the SO₃H group on the cation and hydrogen sulphate as the anion, their persistence also after extensive washing with ethanol, methanol, toluene, and water strongly suggested the presence of a covalent linkage. Previously, we hypothesized⁴³ the transformation of the hydroxyl groups on sporopollenin into the corresponding sulphate monoesters, through a process probably catalyzed by the acidic IL. This supposition finds a further support in the fact that the FTIR spectrum of a sulfonated sporopollenin, recently prepared by treating sporopollenin with chlorosulfonic acid,³⁷ turns out to be very similar to the spectrum presented in this work, the two aforementioned peaks being present in both spectra.

Scheme 1 Preparation of ILs functionalized SEC.

Although this functionalization could negatively affect the subsequent functionalization reactions, fortunately, the treatment of the isolated SEC with a solution of (3-chloropropyl) triethoxysilane (CPTES), following a procedure similar to that recently reported in the literature,⁴⁴ gave the desired Si-functionalized sporopollenin, **CPS-SEC**. **CPS-SEC** were further transformed into IL-modified sporopollenin capsules (**5a-d**) by reaction with four different 1-alkylimidazoles (**4a-d**), Scheme 1.

In particular, three natural alcohols, namely (-)-nopol (**1a**), (S)-(-)-β-citronellol (**1b**) and (-)-myrtenol (**1c**), which are also chiral, were used as starting materials to synthesize the respective 1-alkylimidazoles in a two step process. (-)-Nopol and (S)-(-)-β-citronellol were transformed, in very high yields, into the corresponding mesylates (**2a-b**) by reaction with methanesulfonyl chloride, in the presence of Et₃N, and the isolated compounds **2a-b** were reacted with an equimolar amount of sodium imidazolate. Interestingly, when the same approach was performed on (-)-myrtenol, only the corresponding allyl chloride (**3c**) was isolated in good yield. This probably arises from the displacement by the chloride of the first formed mesylate. Reaction of **3c** with sodium imidazolate gave the expected product (**4c**) in good yield (Scheme 2).

Chiral imidazole **4d** was obtained instead starting from L-phenylalanine, glyoxal, formaldehyde, and ammonia through the Debus-Radziszewski reaction.⁴⁵ The desired product **4d** was isolated in 48% yield, in agreement with the literature.⁴⁵

To provide new properties to the IL-modified SEC, an anion metathesis aimed at substituting the chloride anion with the

bis(trifluoromethylsulfonyl)imide anion was performed on compounds **5a** and **5d**. This kind of anion metathesis is usually performed to prepare highly hydrophobic ionic liquids. Likewise, the presence of this heavily fluorinated anion could determine the hydrophilic-hydrophobic switch of the sporopollenin surface, contemporaneously, increasing the thermal stability of the resulting material. The well-known tunability of ILs can become an efficient method to modify the whole sporopollenin surface. The reaction was carried out by suspending the IL-functionalized sporopollenin in an aqueous solution of LiTf₂N and stirring the mixture at room temperature for 48 hours, to give derivatives **6b** and **6d** (Scheme 1).

IL modified sporopollenins **5a-d**, the related Tf₂N derivatives, and their precursors were characterized by means of ATR-FTIR, SEM, EDX, solid-state ¹³C NMR analyses and TGA.

ATR-FTIR analysis and focal plane array imaging of the IL-functionalized SEC

Pollen grains and their modified forms were initially characterized by ATR-FTIR. The spectrum of CPTES immobilized sporopollenin **CPS-SEC** (Fig. 1) shows the characteristic adsorption band of the Si-O stretching at 1036 cm⁻¹, demonstrating that the modification was successful. In Fig. 1 are also reported the IR spectra of the sporopollenin derived from the treatment with [C₄mimSO₃H][HSO₄] (SEC) and the (S)-(-)-β-citronellol IL-functionalized sporopollenin both with Cl⁻ and Tf₂N⁻ counterions, as examples of bio-based supported derivatives. These latter, although very similar to the **CPS-SEC**

Scheme 2 Preparation of alkylimidazoles.

spectrum, show the distinctive absorption bands of the imidazolium moiety (around 1600 cm^{-1} and between 1109 cm^{-1} and 1132 cm^{-1}). On the other hand, after anion exchange the typical strong absorption of CF_3 and SO_2 can be evidenced (asymmetric stretching of CF_3 , around 1200 cm^{-1} , asymmetric and symmetric stretching of SO_2 , around 1350 and $1190\text{--}1130\text{ cm}^{-1}$, respectively). It is noteworthy that, although these bands in the case of free ILs often show the most pronounced dependence on the state of salt (liquid–solid) and CF_3 and SO_2 are the principal moieties involved in the cation and anion interactions, in this case moderate (if any) changes have been observed with respect to analogous not supported ILs, based on 1-alkyl-3-methylimidazolium cations. This suggests that, as desired, the grafting of the IL on the SEC surface is not accompanied by

strong interactions between IL and support: thus, the IL should largely maintain their peculiar physico-chemical features.

For selected sporopollenin samples, false-colour images were obtained using the Focal Plane Array (FPA) imaging technique, as shown in Fig. 2. For each sample, a real-colour optical image was first collected to select the area for imaging. Subsequently, after the FTIR spectra of the sample were recorded for each pixel, a wavenumber was selected in order to obtain information about the spatial distribution of specific chemical components on the micro-capsules. The colours of the pixels span from red to blue, indicating an increasing absorbance on that pixel at the specified wavenumber. Fig. 2 illustrates visible and FPA images of 3-chloropropyl-functionalized sporopollenin CPS-SEC, and IL-

Fig. 2 Optical and FPA images: (a) 2D image (blue is high) of 3-chloropropyl-functionalized sporopollenin CPS-SEC, selected wavenumber 1035 cm^{-1} ; (b) 3D image (red is high) of CPS-SEC; (c) 2D image of IL-functionalized sporopollenin **5b** at 1035 cm^{-1} ; (d) 2D image of **5b** at 1563 cm^{-1} . Red circles indicate intact pollen grains, whereas red squares show pollen fragments.

Fig. 3 SEM images of (a) sporopollenin extracted with the IL $[\text{HSO}_3\text{C}_4\text{mim}][\text{HSO}_4]$, (b) 3-chloropropyl-functionalized sporopollenin CPS-SEC and (c) IL-functionalized sporopollenin 5b.

functionalized sporopollenin, respectively. Data referred to pollen grains treated with $[\text{C}_4\text{mimSO}_3\text{H}][\text{HSO}_4]$ are not shown as they are in good agreement with results obtained in our previous work.⁴³ The blue colour distribution in the FPA images of Fig. 2a and b (2D and 3D images, respectively), related to CPS-SEC sample, confirms not only that Si-derivatization has been carried with success but also that Si is well-distributed on the SEC surface. In this case, the wavenumber selected is 1035 cm^{-1} , which is the characteristic band of Si–O bond stretching mode. In the lower row of Fig. 3, the optical image of CPS-SEC functionalized with (*S*)-(–)- β -citronellol Cl ionic liquid, sporopollenin 5b, is shown on the left. On the right, is the false-colour image at two selected wavenumbers. In Fig. 2c, the wavenumber is 1035 cm^{-1} corresponding to silanyl moieties, corroborating the fact that Si–O groups are always well distributed, while in Fig. 3d the referring band is 1563 cm^{-1} , typical of imidazolium-based compounds. As seen from the false colour image, blue-green is also in this case quite well distributed on the surface of the analyzed sample, revealing an efficient functionalization of sporopollenin with chiral bio-based ionic liquid.

SEM imaging and energy-dispersive X-ray (EDX) spectroscopy of the IL-functionalized SEC

In order to observe their morphology, SEM images were collected for the sporopollenin samples (Fig. 3). The sporopollenin capsule obtained after treatment with the acidic ionic liquid $[\text{HSO}_3\text{C}_4\text{mim}][\text{HSO}_4]$ is shown in panel a. The characteristic microstructure of the exine surface is partially lost after the treatment; moreover, the diameter of the capsule decreases slightly due to the removal of the intine layer and the interior protoplast. However, the circular shape is still well recognizable. Panel b illustrates a SEM image of the 3-chloropropyl-modified sporopollenin CPS-SEC, in which the presence on the sporopollenin capsule of an additional external layer can be observed, as well as the presence of some minor fragments on the capsule surface. Finally, panel c represents IL-functionalized sporopollenin 5b. As observed for all the other bio-based IL-functionalized sporopollenin synthesized (ESI[†]), the SEM image is similar to that of CPS-SEC, showing that the last reaction, IL grafting, has only a very few (if any) effect on capsule size and morphology.

Finally, to detect elements not revealed by elemental analysis EDX microanalyses were performed on some of the

sporopollenin samples (Fig. S3[†]). As expected, the spectrum of the pristine pollen shows a large variety of elements apart from carbon, nitrogen, oxygen, and sulphur. In particular, sodium, magnesium, phosphorus, potassium, iron, and lead were also detected. All these elements disappear in the EDX spectrum of the 3-chloropropyl-functionalized sporopollenin CPS-SEC, whereas silicon and chlorine are clearly visible. According to this analysis, the silicon concentration turns out to be around 0.58 mmol per gram of CPS-SEC. Among the IL-modified sporopollenin materials, 5a and 5b were chosen to perform the EDX microanalysis. The spectra show the presence of carbon, nitrogen, oxygen, sulphur, silicon, and chlorine as the most abundant elements. In particular, the ratio between Si/N changes in these latter samples in accordance with the IL functionalization.

Solid-state ^{13}C NMR analyses

IL-functionalized sporopollenin 5a was examined also by ^{13}C CP-MAS NMR spectroscopy. The spectrum obtained with 12 kHz sample rotation (Fig. 4) shows no appreciable spinning sidebands (95 ppm intervals), as verified by spinning at 8 kHz (see ESI Fig. S1[†]), indicating that the organic species giving the most intense peaks are not rigid solids. Several resolved peaks (10, 38, 41, 46, 122 ppm) correspond to those expected for 5a (Fig. S2[†]) can be indeed easily evidenced. However, there are also some extra species giving signals near 70 and 100 ppm (C–O), 150 ppm (oxygenated aromatics), 170 ppm (carboxylate) and 200 ppm (ketones), attributable to the SEC support.

The largest signal at 30 ppm, due to aliphatic carbons, was also observed for SEC, along with the sharp signal at 129 ppm. Sporopollenins contain aromatic (129 ppm) and aliphatic (30 ppm) carbons thought to originate from the phenylpropanoid pathway and from waxes of the exine.⁴⁶ These two ^{13}C signals have surprisingly short longitudinal relaxation times, being well evidenced even with re-cycle delays of only 0.3 s (Fig. S1[†]). Clearly, the carbon nuclei giving these signals are near paramagnetic sites (unpaired electrons). The paramagnetic properties of these materials, which will be more in detail examined in the future, could be of interest for specific applications, for instance for the development of bio-inspired paramagnetic particle labels to be used in magneto immunoassay, as well as for a more generic antioxidant activity.

Fig. 4 ^{13}C CP-MAS NMR spectrum of sporopollenin (SEC) and IL-functionalized sporopollenin 5a.

Thermogravimetric analyses of IL-functionalized SEC

Finally, functionalized and non-functionalized sporopollenin microcapsules were also characterized by thermal gravimetric analysis, under nitrogen. Since it is well-known that temperature ramp in TGA measurements causes mass loss resulting from either thermal decomposition or evaporation of ILs and the temperature profile depends on some operating factors, such as heating rate, instrumentation, type of carrier gas, and sample amount, measurements were carried out under identical conditions. The maximum thermal degradation temperature of sporopollenin arising from IL treatment was recorded at 431 °C (Fig. S4†), in agreement with the high thermal stability of this biopolymer. It is worth noting the presence of a small shoulder at around 250 °C on the DTG plot that can be attributed to a first partial degradation, due to oxygen release. On the other hand, TGA of lightly washed sporopollenin, containing residual acidic IL, gave a well-distinguishable additional peak at about 200 °C, which disappeared after refluxing the sporopollenin in methanol (data not shown). The CPTES-modified sporopollenin showed a similar trend to the washed sporopollenin, with the principal peaks shifted toward higher temperatures (451 °C). Furthermore, the total weight loss was about 5% less for the modified sporopollenin than the unmodified one (Fig. 5a). This is probably due to the presence of silica atoms in the former. The thermogram of the IL-modified sporopollenin 5b presents two new peaks at 208 °C and 291 °C, which can be attributed to the degradation of the grafted IL moiety (Fig. 5b), whereas the maximum thermal degradation occurs at 448 °C, *i.e.* at a temperature which is close to the value of the unmodified sporopollenin. Interestingly, the degradation profile of the IL-modified sporopollenin 6b (Fig. 5b) shows instead only a small degradation peak at 204 °C (<5%), it principally decomposes at 437 °C. As expected, the thermal stability of the sporopollenin supported ionic liquids depends on counter anion: analogously to the situation characterizing free ILs, a significant thermal

stability increase has been observed changing the anion from chloride to Tf_2N . Still, this thermal stability is very high for an IL supported on capsules with biological origin and it is a desirable property for a carrier to be used in wide range of temperatures.

Conclusions

We believe that our approach, based on simple reactions, can provide new smart 3D-microcapsules exploiting the unique properties of pollen grains and tailor-made ionic liquids.

Treatment with $[\text{C}_4\text{mimSO}_3\text{H}][\text{HSO}_4]$ allows to obtain easily sporopollenin capsules through an efficient removal of the other components, mainly cellulose and proteins.

SEM images show that, both after the first treatment and the following ones, the sporopollenin retained its distinctive spherical shape and collapse phenomena having detrimental effects on absorption/release mechanisms, generally observed when harsh purification procedures are used, are largely avoided.

ATR-FTIR/focal plane array imaging and SEM/EDX analyses show that Si and ILs are well distributed on the capsule surface.

Solid-state ^{13}C NMR suggests interesting paramagnetic properties of these materials.

Finally, thermal analyses of IL decorated sporopollenin capsules evidence a high stability of these materials, which depend largely on IL anion. The degradation profile of the IL-modified sporopollenin 6b shows indeed only a small degradation peak at 204 °C (<5%), it principally decomposes at 437 °C.

To the best of our knowledge, this is the first example of sporopollenin capsules decorated with positively charged moieties. Normally, sporopollenin possess ionisable groups on their surface that become increasingly negatively charged with an increase in pH.⁴⁷ The presence of positive charges could instead facilitate the adhesion of these materials to negatively-charged surfaces, such as negatively charged synthetic materials or the cell membranes of a range of bacteria.

Nonetheless, the obtained thermal stable bio-based IL-SEC hybrid structures may lead to improved systems for many of the fields mentioned in the introduction and may clear the way for the development of new applications. For instance, surface modification of sporopollenin has recently allowed for the development of micromotors able to transport bovine serum albumin loaded into the microcavity.⁴⁸ The proposed modification, which also permit the tuning of the hydrophobic/hydrophilic surface properties by means of the metathesis reaction, could further boost research into this direction, with an extra option of target oriented micromotors exploiting the chiral centers present on the bio-based ILs moiety.

Experimental section

Materials

(S)(-)- β -Citronellol, (-)-myrtenol, and (-)-nopol were purchased from Sigma Aldrich. 1-Methylimidazole was obtained by Alfa Aesar. Phenylalanine and aqueous ammonia

Fig. 5 a) Temperature-ramped TGA thermographs of CPS-SEC (dash dot line), IL functionalized sporopollenin 5b (solid line) and IL functionalized sporopollenin 6b (short dash line) with a heating rate of $10\text{ }^{\circ}\text{C min}^{-1}$. (b) Temperature-ramped TGA thermographs of CPS-SEC (dash dot line), IL functionalized sporopollenin 5b (solid line) and IL functionalized sporopollenin 6b (short dash line).

(33%) were obtained from Fluka, whereas aqueous glyoxal (40%) and aqueous formaldehyde (37%) were purchased from Sigma Aldrich and Acros Organics, respectively. (3-Chloropropyl)triethoxysilane was obtained from Sigma Aldrich. Defatted pollen from *Populus deltoides* was purchased by Sigma Aldrich. All substances were used as received, without further purification, unless specified otherwise. All organic solvents were purchased from Sigma Aldrich and used without further purification.

Methods

TLC analysis were performed on aluminium-supported silica sheets (Merck TLC Silica gel 60 F254). The identification of the spots was carried out with an UV lamp (CAMAG, $\lambda = 254\text{ nm}$)

and/or by wetting the TLC with a 100g L^{-1} ethanol solution of phosphomolybdic acid ($\text{MoO}_3 \cdot \text{H}_3\text{PO}_4$) and heating it. Solution state NMR spectra were recorded on a Bruker Avance II 250 spectrometer at 250.13 MHz (^1H) and 52.90 MHz (^{13}C) using tetramethylsilane as internal standard. The following abbreviations are used: s = singlet, d = doublet, dd = double doublet, t = triplet, tt = triplet of triplets, td = triplet of doublets, qa = quartet, qi = quintuplet, m = multiplet. Solid state ^{13}C NMR spectra were collected at 126 MHz , using a Varian 500 spectrometer and high power ^1H “spinal” decoupling, for samples contained in 4 mm rotors spinning at 14 kHz (CP) or at 8 kHz (one pulse). A contact time of 2 ms was used for ^1H - ^{13}C cross-polarization (“tanpax” program). One pulse ^{13}C spectra were collected using a composite (90° - 180° - 180°) excitation pulse, “onepuldpth” with 16-phase cycling to suppress the Kel-F

spacer signal adapted from ref. 49, $4.2 \mu\text{s} = 90^\circ$ pulse, variable relaxation delay and shifts referenced to adamantane (38.5 and 29.4 ppm). ATR-FTIR spectra were recorded with an IR Cary 660 FTIR spectrometer (Agilent Technologies) using a macro-ATR accessory with a Zn/Se crystal. The spectra were measured in a range from 4000 to 500 cm^{-1} , with 32 scans both for background and samples. Chemical imaging data was collected by Agilent's ATR-imaging technique using a FTIR Cary 620 imaging system equipped with a 64×64 Focal Plane Array (FPA) detector cooled by liquid nitrogen. Spectra were measured, from 3300 to 900 cm^{-1} , with 256 scans for both background and pollen samples. Thermal gravimetric analysis was performed on a TGA Q 500 (TA instruments), under nitrogen. For the sporopollenin-based materials: ramp $10.00 \text{ }^\circ\text{C min}^{-1}$ to $900.00 \text{ }^\circ\text{C}$, isothermal for 2.00 min. Elemental analyses of the pristine and the IL-treated pollen were carried out on a Thermo Finnigan model Flash 1112 CHNS-O elemental analyzer at the RIAIDT of the University of Santiago de Compostela (USC, Spain). SEM images were acquired on sporopollenin and IL-modified sporopollenin using a Quanta FEG 450 SEM from FEI. Typical imaging conditions were: pressure 90 Pa (low-vacuum mode), accelerating voltage 15 kV, back scattered electrons detector. EDX analysis were performed with an X-Flash 6|10 instrument from Bruker.

Synthesis of nopol mesylate (2a), citronellol mesylate (2b), and myrtenol chloride (2c). The 8.32 g (50.0 mmol) of (–)-nopol (1a) and 7.2 mL of Et_3N (51 mmol) were dissolved in 25 mL of CH_2Cl_2 in a 250 mL one-neck round-bottom flask. A solution of 4.0 mL of methanesulfonyl chloride (51 mmol) in 20 mL of CH_2Cl_2 was added under stirring at $0 \text{ }^\circ\text{C}$ within 30 minutes. The mixture was further stirred at room temperature until the TLC analysis ($\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$) demonstrated total consumption of alcohol. If the alcohol was still present after 24 hours, 0.2 equivalents of Et_3N and methanesulfonyl chloride were added to the mixture. The reaction was quenched by adding 50 mL of a saturate solution of NaHCO_3 , and the aqueous phase was extracted three times with 20 mL of CH_2Cl_2 . The collected organic phases were washed with 50 mL of milliQ water, and dried over MgSO_4 . After filtration, the solvent was removed under reduced pressure obtaining 12.11 g (49.6 mmol) of (1*R*,5*S*)-2-(6,6-dimethylbicyclo[3.1.1]hept-2-en-2-yl)ethyl methanesulfonate (2a). Yield 99%. TLC: $R_f = 0.88$ (SiO_2 , $\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$).

$^1\text{H NMR}$ (250.13 MHz, CDCl_3) δ (ppm): 5.35 (s, 1H), 4.18 (t, 2H), 2.97 (s, 3H), 2.37 (m, 3H), 2.21 (s, 2H), 2.03 (m, 2H), 1.25 (s, 3H), 1.12 (d, 1H), 0.81 (s, 3H).

$^{13}\text{C NMR}$ (52.90 MHz, CDCl_3) δ (ppm): 142.4, 119.8, 67.9, 45.4, 40.4, 37.9, 37.3, 36.2, 34.6, 31.2, 26.1, 21.0.

The synthesis of (3*S*)-3,7-dimethyloct-6-en-1-yl-methanesulfonate (2b) is analogous to that described for compound 2a. Yield 99%.

TLC: $R_f = 0.88$ (SiO_2 , $\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$).

$^1\text{H NMR}$ (250.13 MHz, CDCl_3) δ (ppm): 5.03 (tt, 1H), 4.21 (td, 2H), 2.95 (s, 3H), 1.94 (m, 2H), 1.64 (s, 3H), 1.56 (s, 3H), 1.83–1.08 (m, 5H), 0.89 (d, 3H).

$^{13}\text{C NMR}$ (52.90 MHz, CDCl_3) δ (ppm): 131.6, 124.5, 68.8, 37.4, 36.9, 29.1, 25.9, 25.4, 19.3, 18.8.

The synthesis of (1*R*,5*S*)-2-(chloromethyl)-6,6-dimethylbicyclo[3.1.1]hept-2-ene (3c) is analogous to that described for compound 2a. Yield 96%.

TLC: $R_f = 0.89$ (SiO_2 , $\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$).

$^1\text{H NMR}$ (250.13 MHz, CDCl_3) δ (ppm): 5.59 (s, 1H), 3.97 (s, 2H), 2.41 (m, 1H), 2.26 (m, 3H), 2.08 (m, 1H), 1.29 (s, 3H), 1.17 (d, 1H), 0.82 (s, 3H).

$^{13}\text{C NMR}$ (52.90 MHz, CDCl_3) δ (ppm): 144.4, 122.7, 48.9, 44.5, 40.7, 38.3, 31.9, 31.6, 26.3, 21.4.

Synthesis of nopol (4a), citronellol (4b), and myrtenol (4c) imidazole. A 250 mL three-neck round-bottom flask was equipped with a vacuum adapter and connected to the argon line. After flushing argon for a minute, 3.27 g of a 60% (w/w) NaH oil suspension (81.6 mmol of NaH) were added to the flask and washed three times with 20 mL of hexane, which was removed with a Pasteur pipette after one minute of gentle stirring. At this stage, THF (10 mL) was added, and the flask was equipped with two addition funnels containing 2.79 g (41.0 mmol) of imidazole in 20 mL of THF and 5.02 g (20.6 mmol) of 3a in 20 mL of THF, respectively. The imidazole solution was carefully added dropwise at $0 \text{ }^\circ\text{C}$, to avoid excessive effervescence. After stirring for 10 minutes, the mesylate solution was added slowly at $0 \text{ }^\circ\text{C}$ over 15 minutes, and the mixture was allowed to warm up to room temperature and further stirred for 24 hours. As the TLC showed the presence of 3a, the temperature was raised to $50 \text{ }^\circ\text{C}$, and the reaction was continued until total conversion of the mesylate precursor was observed. The reaction was quenched by slowly adding water to the mixture, until no more hydrogen gas evolved. The solvent was evaporated under reduced pressure. 50 mL of water and 50 mL of CH_2Cl_2 were added, and the aqueous phase was further extracted with two portions of CH_2Cl_2 (50 mL). The merged organic phases were washed with 100 mL H_2O , and dried over MgSO_4 . After filtration, evaporation of the solvent, and flash chromatography purification ($\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$), 3.42 g (15.8 mmol) of a light yellow liquid was obtained. Yield 87%. [α] $^20_{\text{D}}$ –21.6 (c 1.1, CHCl_3).

TLC: $R_f = 0.35$ (SiO_2 , $\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$).

$^1\text{H NMR}$ (250.13 MHz, CDCl_3) δ (ppm): 7.38 (s, 1H), 6.96 (s, 1H), 6.84 (s, 1H), 5.20 (m, 1H), 3.88 (t, 2H), 2.34 (m, 3H), 2.14 (m, 2H), 1.98 (m, 2H), 1.22 (s, 3H), 1.06 (d, 1H), 0.75 (s, 3H).

$^{13}\text{C NMR}$ (52.90 MHz, CDCl_3) δ (ppm): 143.7, 137.0, 129.2, 119.3, 118.7, 45.5, 45.2, 40.6, 38.4, 38.0, 31.6, 31.2, 26.2, 21.1.

The synthesis of 1-[(3*S*)-3,7-dimethyloct-6-en-1-yl]-imidazole (4b) is analogous to that described for compound 4a. Yield 94%. [α] $^20_{\text{D}}$ –2.7 (c 0.9, CHCl_3).

TLC: $R_f = 0.43$ (SiO_2 , $\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$).

$^1\text{H NMR}$ (250.13 MHz, CDCl_3) δ (ppm): 7.40 (s, 1H), 6.99 (s, 1H), 6.85 (s, 1H), 5.01 (t, 1H), 3.90 (m, 2H), 1.63 (s, 3H), 1.54 (s, 3H), 2.00–1.00 (m, 7H), 0.89 (s, 3H).

$^{13}\text{C NMR}$ (52.90 MHz, CDCl_3) δ (ppm): 137.2, 131.8, 129.5, 124.4, 118.9, 45.2, 38.3, 36.9, 29.9, 25.9, 25.5, 19.4, 17.8.

The synthesis of 1-[(1*R*,5*S*)-6,6-dimethylbicyclo[3.1.1]hept-2-en-2-yl]methyl-imidazole (4c) is analogous to that described for compound 4a. Yield 76%. [α] $^20_{\text{D}}$ –29.0 (c 1.4, CHCl_3).

TLC: $R_f = 0.43$ (SiO_2 , $\text{CH}_2\text{Cl}_2 : \text{MeOH } 95 : 5$).

^1H NMR (250.13 MHz, CDCl_3) δ (ppm): 7.40 (s, 1H), 6.99 (s, 1H), 6.83 (s, 1H), 5.43 (s, 1H), 4.36 (s, 2H), 2.50–1.80 (m, 5H), 1.19 (s, 3H), 1.09 (d, 1H), 0.72 (s, 3H).

^{13}C NMR (52.90 MHz, CDCl_3) δ (ppm): 143.2, 137.2, 139.1, 121.3, 119.2, 51.9, 43.4, 40.4, 37.9, 31.6, 31.1, 25.9, 20.9.

Synthesis of methyl (2S)-2-(imidazol-1-yl)-3-phenylpropanoate-imidazole (4d). 4.05 g (49.9 mmol) of 37% (w/w) formaldehyde aqueous solution and 7.22 g (49.7 mmol) of glyoxal 40% (w/w) aqueous solution were introduced into a 100 mL two-neck round-bottom flask. The latter was equipped with a condenser and an addition funnel containing a solution composed of 8.26 g (50.0 mmol) of phenylalanine, 2.02 g (50.6 mmol) of NaOH, 2.90 mL (56.2 mmol) of 33% (w/w) NH_3 aqueous solution, and 30 mL of milliQ water. After heating the flask at 50 °C, the solution was added over 30 minutes, and the resulting mixture was further stirred for 4 hours, always maintaining the temperature at 50 °C. The brown solution was transferred into a 250 mL round-bottom flask, and the solvent was evaporated under reduced pressure. The resulting solid was dissolved in 100 mL (2.47 mol), and 7.3 mL (101 mmol) of SOCl_2 were added at 0 °C within 10 minutes. The mixture was refluxed for 24 hours, while periodically checking its progress by TLC analysis (EtOAc). The solvent was then evaporated under vacuum, and the excess SOCl_2 was removed by redissolving the dark solid in 50 mL MeOH and applying a vacuum. This operation was repeated twice. The crude solid was purified by flash chromatography (EtOAc), affording 5.31 g (23.0 mmol) of a brown viscous liquid. Yield 46%. $[\alpha]_{\text{D}}^{20} = -59.0$ ($c = 1.1$, methanol), in agreement with literature.⁵⁰

TLC: $R_f = 0.31$ (SiO_2 , EtOAc).

^1H NMR (250.13 MHz, CDCl_3) δ (ppm): 7.35 (s, 1H), 7.17 (m, 2H), 7.00 (s, 2H), 6.95 (m, 2H), 4.85 (dd, 1H), 3.70 (s, 3H), 3.41 (dd, 1H), 3.16 (dd, 1H), 1.22 (s, 3H), 1.06 (d, 1H), 0.75 (s, 3H).

^{13}C NMR (52.90 MHz, CDCl_3) δ (ppm): 169.41, 136.75, 135.09, 129.29, 128.59, 128.50, 127.22, 117.86, 61.21, 57.20, 39.39.

Synthesis of 4-(3-methylimidazolium-1-yl)butane-1-sulfonate. 19.8 g (241 mmol) of methylimidazole and 30.0 g (220 mmol) of 1,4-butane sultone were introduced into a 500 mL one-neck round-bottom flask, along with 200 mL of MeCN. The flask was equipped with a condenser, and the solution was stirred at 90 °C for 48 hours. The milky mixture obtained was filtered on a Buchner funnel, and the white powder on the filter was washed with cold MeCN and dried under vacuum, recovering 45.2 g (207 mmol) of a white powder. Yield 94%. Then, an equimolar amount of concentrated H_2SO_4 was carefully added dropwise at 0 °C, and the mixture was stirred at room temperature for 1 hour. The solvent was evaporated under reduced pressure, obtaining the uncoloured viscous ionic liquid $[\text{HSO}_3\text{C}_4\text{mim}][\text{HSO}_4]$.

^1H NMR (250.13 MHz, CD_3OD) δ (ppm): 9.01 (s, 1H), 7.70 (t, 1H), 7.61 (t, 1H), 4.30 (t, 2H), 3.79 (s, 3H), 2.88 (t, 2H), 2.09 (qi, 2H), 1.81 (qi, 2H).

^{13}C NMR (52.90 MHz, CD_3OD) δ (ppm): 138.8, 125.7, 124.5, 52.3, 51.0, 37.3, 30.7, 23.6.

Extraction of sporopollenin exine capsules (SEC) from *Populus deltoides* pollen. 2.50 g of defatted *Populus deltoides* pollen were added to the $[\text{HSO}_3\text{C}_4\text{mim}][\text{HSO}_4]$ ionic liquid and the

mixture was heated to 160 °C for 80 minutes under continuous stirring. The reaction was quenched by adding 100 mL of milliQ water. The suspension was filtered on a Buchner funnel, and the black solid was washed with milliQ water and then with methanol. For each solvent, the washing was continued until the filtrate was colourless. The black/brown powder was dried at 60 °C overnight, obtaining 0.46 g of sporopollenin.

Synthesis of the 3-chloropropyl-functionalized SEC (CPS-SEC). In a 50 mL one-neck round-bottom flask, 0.46 g of sporopollenin were suspended in 20 mL of toluene, and 1.85 mL (7.68 mmol) of (3-chloropropyl)triethoxysilane were added. The suspension was refluxed for 48 hours under continuous stirring. At the end of the reaction, the solid (0.51 mg) was recovered by filtration on Buchner funnel, washed with toluene and then with methanol, and dried at 60 °C overnight.

Synthesis of SEC-supported ILs (5a–d). In a 50 mL one-neck round-bottom flask, 0.100 g of sporopollenin were suspended in 10 mL of toluene containing 1.5 mmol of 1-alkylimidazole (4a–d). The suspension was stirred under reflux condition for 48 hours. At the end of the reaction, the solid (0.120 mg) was recovered by filtration on Buchner funnel, washed with toluene and then with methanol, and dried at 60 °C overnight.

Synthesis of hydrophobic ILs-modified SEC (6b, 6d). 20 mg of SEC-supported ILs (5b and 5d) were suspended in 0.5 mL of milliQ water containing 0.100 g (0.35 mmol) of LiTf_2N and stirred at room temperature for 48 hours. The solid (22 mg) was recovered by filtration and dried at 60 °C overnight.
