Received 4 May 2001/Returned for modification 8 August 2001/Accepted 17 September 2001

**Sequences of the *folP1*, *rpoB*, and *gyrA* genes were analyzed for 88 isolates of *Mycobacterium leprae* from leprosy patients in Japan, Haiti, Indonesia, Pakistan, and the Philippines. Thirteen isolates (14.8%) showed representative mutations in more than two genes, suggesting the emergence of multidrug-resistant *M. leprae*.**

Leprosy is a chronic infectious disease caused by *Mycobacterium leprae* and is still a major health problem in several countries of Asia, Latin America, and Africa. Global efforts to control leprosy by intensive chemotherapy have led to a significant decrease in the number of registered patients. However, the annual reports of new cases indicate more than 500,000 even after the introduction of multidrug therapy (MDT) by the World Health Organization (WHO) (19). Current recommended control measures for treating leprosy with MDT are designed to prevent the spread of drug-resistant *M. leprae*. However, drug resistance has been reported since 1964 for dapsone (12), 1976 for rifampin (5), and 1996 for ofloxacin (7).

To prevent the emergence and transmission of multidrug-resistant (MDR) leprosy and to identify and treat existing cases of MDR leprosy, it is necessary to establish rapid methods for detection of drug resistance in *M. leprae*. However, *M. leprae* has not been cultivated on artificial media; therefore, to identify drug susceptibility patterns, bacteria must be tested using Shepard's mouse footpad assay (14). This in vivo method requires at least 6 months and relatively large numbers of bacteria. Recently, there have been advances in the elucidation of molecular events responsible for drug resistance in mycobacteria (6, 11, 13).

In the present study, we analyzed the DNA sequences of particular regions of *M. leprae folP1*, *rpoB*, and *gyrA*, which are responsible for resistance to dapsone, rifampin, and fluoroquinolones, respectively. Several *M. leprae* isolates showed point mutations in the genes. These results suggest the emergence of MDR *M. leprae*.

**Bacterial isolates and materials.** A total of 88 *M. leprae* isolates, obtained from patients receiving antileprosy chemotherapy, were used in this study. The treatments and status of the leprosy patients are listed in Table 1. The treatment history for the patient from whom Zensho-4 was isolated has been described in detail (10). All available details of the cases are

listed; however, for some cases, the details are unclear because records were not available. The patients in Japan were individually taking original medical treatments, including monotherapy. The patients in countries other than Japan received the WHO treatment regimen for multibacillary leprosy, except for a Pakistani case. For patients whose condition was improved by medical treatment had a return of leprosy with an increasing bacillary index after 5 to 10 years, the word "relapse" is used in Table 1. In cases Haiti-1 and Peshawar-5, the condition did not improve, though the patients were treated continuously. *M. leprae* isolates were obtained from biopsy samples of patients with leprosy (multibacillary type) or from footpads of mice infected with *M. leprae*: Japan (21 cases: 15 biopsy samples and 6 footpads), Haiti (1 biopsy sample), Indonesia (30 biopsy samples), Pakistan (8 biopsy samples), and Philippines (28 biopsy samples). The Thai 53 strain of *M. leprae*, which was obtained from a patient with lepromatous leprosy in Thailand, was established at the Leprosy Research Center, National Institute of Infectious Diseases, Japan, by passages in nude mice. Informed consent was obtained from all patients, and human experimentation guidelines of the Ministry of Health, Labour and Welfare, Japan, were followed.

**Sample preparation for PCR.** Thai 53 was used as an antimicrobial-sensitive standard. Leprosy bacilli were purified from infected tissues, and extraction of chromosomal DNA was carried out as previously described (2, 3).

**PCR amplification and DNA sequencing.** PCR was carried out using Ex *Taq* DNA polymerase (Takara Shuzo Co., Shiga, Japan) in a 50- $\mu$ l volume containing 150 ng of genomic DNA and 1  $\mu$ M concentrations of the primers, which were designed according to the sequence of the *folP1* (accession no. AL023093), *rpoB* (Z14314), and *gyrA* (Z70722) genes of *M. leprae*. The primers used for amplification of the *folP1* gene were folP1-1 (5'-GCTTCTCGTGCCGAAGCGCTCG-3') and folP1-2 (5'-GCCATCGCGGGATCTGCTCGCCCA-3'). The primers for the *rpoB* gene were rpoB-1 (5'-CAGACGCTGATCAATATCGT-3') and rpoB-2 (5'-TACGGTGTTCGATGAACCCG-3'). For the *gyrA* gene, gyrA-1 (5'-ATGACTGATATCACGCTGCCA-3') and gyrA-2 (5'-ATAACGCATCGCTGCCGGTGG-3') were used. The target regions of the *rpoB* and *gyrA* genes were amplified by a PC 800 thermal cycler (Astech Co.,

Fukuoka, Japan) with a program of 30 s at 95°C, 2 min at 50°C, and 3 min at 72°C for 40 cycles. For amplification of the target region of the *folP1* gene, the cycling conditions were 95°C for 30 s, 60°C for 2 min, and 72°C for 3 min for 35 cycles. DNA samples for sequencing were recovered from agarose gels using an Easy Trap DNA purification kit (Takara Shuzo) after electrophoresis and ligated to pGEM-T vector (Promega Co., Madison, Wis.). At least two independent clones were subjected to sequencing. Both strands of recombinant plasmids were sequenced with a BigDye terminator cycle sequencing FS Ready Reaction kit (Perkin-Elmer Applied Bio systems, Norwalk, Conn.) and an ABI Prism 310 genetic analyzer (Perkin-Elmer). The nucleotide sequences obtained were analyzed by the DNASIS computer program (Hitachi Software Engineering, Yokohama, Japan).

**Mouse footpad assay.** The in vivo drug susceptibility of *M. leprae* was determined by the method of Shepard (14). The conditions of the assay were as previously described (10).

**Dapsone resistance.** The involvement of two mutations in the *folP1* gene of dapsone-resistant *M. leprae* has been reported (9, 17). In this study, 19 isolates showed the reported mutations in the *folP1* gene. One isolate (Zensho-3) showed mutations at positions 157 and 164. They corresponded to Thr→Ala and Pro→Leu at amino acid positions 53 and 55 in dihydropteroate synthase (DHPS), respectively (Table 2). Nine isolates showed an A→G mutation in codon 157 (*M. leprae* numbering [9]), and three isolates had a C→T mutation in codon 158 (Fig. 1). These mutations caused Thr→Ala and Thr→Ile changes at position 53 in DHPS, respectively. Eight isolates (one isolate overlaps because of a double mutation) showed a C-to-T mutation (Pro→Leu) at codon 164 (position 55 of DHPS).

**Rifampin resistance.** Mutations in the *rpoB* gene, encoding the β subunit of RNA polymerase, were reported to result in resistance to rifampin in several mycobacterial species, including *M. leprae* (4, 18). In the present study, 26 isolates showed the mutations which had already been observed in rifampin-

resistant bacteria (Fig. 2). A mutation at histidine 526 (numbering system used in reference 16) was reported frequently in *Mycobacterium tuberculosis* (16, 18) but not in *M. leprae*. The change from aspartic acid to asparagine at position 516 has not been reported for mycobacteria but has been observed in *Escherichia coli* (8). This is the first report that these mutations (His to Tyr at 526 and Asp to Asn at 516) occur in rifampin-resistant *M. leprae*. Among 26 isolates harboring mutations in *rpoB*, two exhibited a mutation at 516 and 11 showed the mutation at histidine 526, showing a tendency similar to that seen in *M. tuberculosis*. Thirteen isolates had mutations (Ser to Leu or Trp) at position 531. One isolate (Shinsei-1) showed a double mutation, Asp→Asn at 516 and Leu→Pro at position 533 (Table 2).

**Ofloxacin resistance.** Mutations in the quinolone resistance-determining region of *gyrA* were also reported for quinolone-resistant mycobacteria (15). Only one case of quinolone resistance in leprosy was reported, from Mali (1). One mutation (Ala→Val at position 91) was detected in five isolates of *M. leprae*, and another mutation (Gly→Cys at position 89) was found as in quinolone-resistant *M. tuberculosis* (15) (Fig. 3).

The drug susceptibilities of Airaku-2, Airaku-3, Zensho-4, and Zensho-5 were confirmed by mouse footpad assay. In the assay, both Airaku-2 and Airaku-3 were dapsone resistant (Table 2). They showed a mutation in the *folP1* gene that has been demonstrated to be responsible for dapsone resistance. In Airaku-3, *rpoB* and *gyrA* had a wild-type sequence. However, the results of the footpad assay showed that Airaku-3 was rifampin resistant and ofloxacin susceptible. The mutations in *rpoB* did not account for rifampin resistance in Airaku-3. Therefore, it is likely that Airaku-3 acquired rifampin resistance by other mechanisms, such as changes in membrane permeability and function of the efflux pump. In Zensho-4, mutations were detected in the *folP1*, *rpoB*, and *gyrA* genes. The mouse footpad assay revealed that the isolate had acquired dapsone, rifampin, and ofloxacin resistance (10) as a result of these mutations. Also, it was found that the mutations in the *folP1* and *rpoB*

TABLE 2. Mutations in *folP1*, *gyrA*, and *rpoB* genes related to drug resistance in clinical isolates of *M. leprae*

<sup>a</sup> The drug susceptibilities of Airaku-2, Airaku-3, Zensho-4, and Zensho-5 were confirmed in a mouse footpad assay. R, resistant; S, susceptible; None, no mutation in the gene positions which were previously reported for other bacteria, such as *E. coli* and *M. tuberculosis*; ND, not determined.

genes brought on resistance to dapsons and rifampin in Zensho-5, as confirmed in the mouse footpad assay.

The most striking finding was that *M. leprae* frequently harbored more than two mutations, suggesting multidrug resistance in this cohort of patients who did not respond to treatment. As shown in Table 2, 11 isolates had mutations in two genes (resistance to two drugs), and 2 strains (Shinsei-1 and Zensho-4) showed mutations in three genes (resistance to three drugs). MDR *M. leprae* (resistant to dapsons, rifampin, and ofloxacin) was first reported in 1997 (1). However, the DNA sequence of *folP1* was not analyzed for confirmation of dapsons resistance in that study. We clearly showed both genetic and mouse footpad confirmation for MDR leprosy (Zensho-4).

Generally, discontinuation of treatments and monotherapy play a major role in production of MDR bacilli. The drug-resistant *M. leprae* generated in the past may recur in Japanese patients. Furthermore, new cases in developing countries had drug-resistant *M. leprae*. MDR *M. tuberculosis* has become a major problem globally. We should take prompt measures against MDR *M. leprae*, because leprosy is caused by mycobacteria like *M. tuberculosis*. However, WHO has not yet consid-

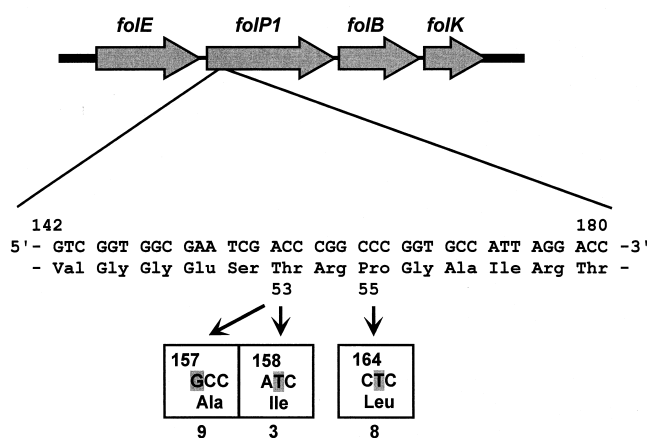

FIG. 1. Nucleotide sequence of the *folP1* gene from Thai 53 and clinical isolates of *M. leprae*. A DNA fragment of *folP1* (388 bp) was amplified by PCR and sequenced. In 19 isolates of *M. leprae*, mutations at positions 53 and 55, which were found to be associated with dapsons resistance, were detected (the numbering system of reference 9 was used). The numbers of cases which had a mutation are shown. One isolate was overlapping in this figure because it had mutations at positions 157 and 164.

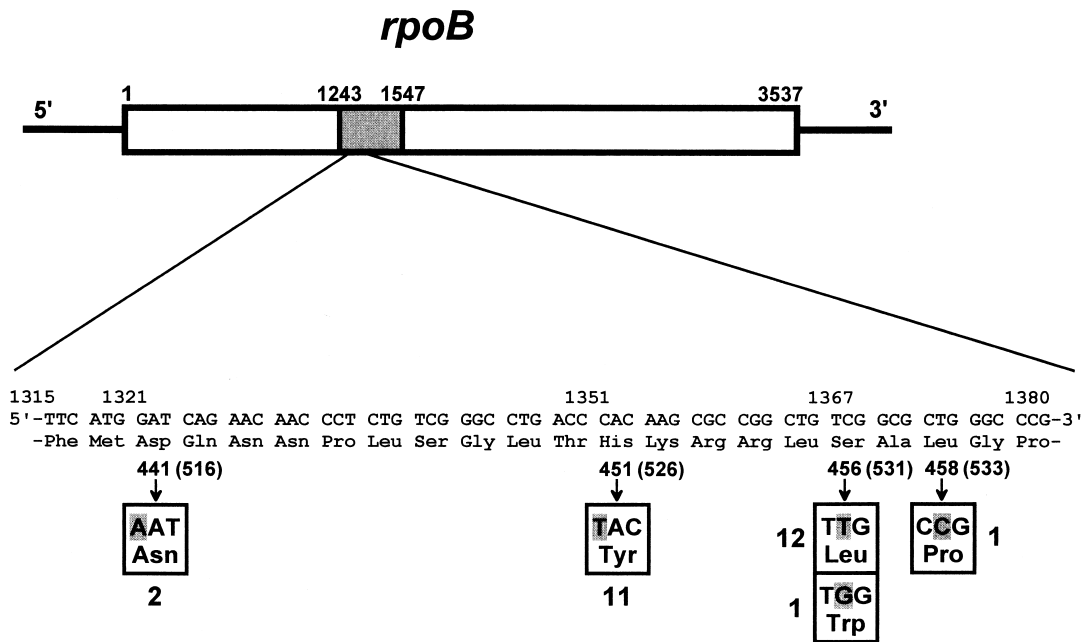

FIG. 2. DNA sequence of the *rpoB* gene from clinical isolates of *M. leprae*. The *rpoB* sequence from positions 1243 to 1547 was amplified and analyzed. Twenty-six isolates had a mutation at position 441 (516), 451 (526), 456 (531), or 458 (533) (*E. coli* numbering in parentheses [16]). One isolate had mutations at positions 441 (516) and 458 (533).

ered drug-resistant *M. leprae*. Our results strongly suggest the importance of a survey of drug resistance in leprosy as well as the establishment of rapid methods for detection of drug-resistant leprosy bacilli. Genetic analysis may provide a powerful tool for rapid detection of drug-resistant *M. leprae* and important information on chemotherapy.

In this study, other mutations were also detected in *folP1*,

*rpoB*, and *gyrA* (data not shown). However, it is not clear that such mutations are linked to drug resistance in *M. leprae*, because there have been no reports on the positions of mutations which are responsible for drug resistance. We are investigating the relationship between genotypic mutations and phenotypic resistance using *M. leprae* isolates in the mouse footpad assay.

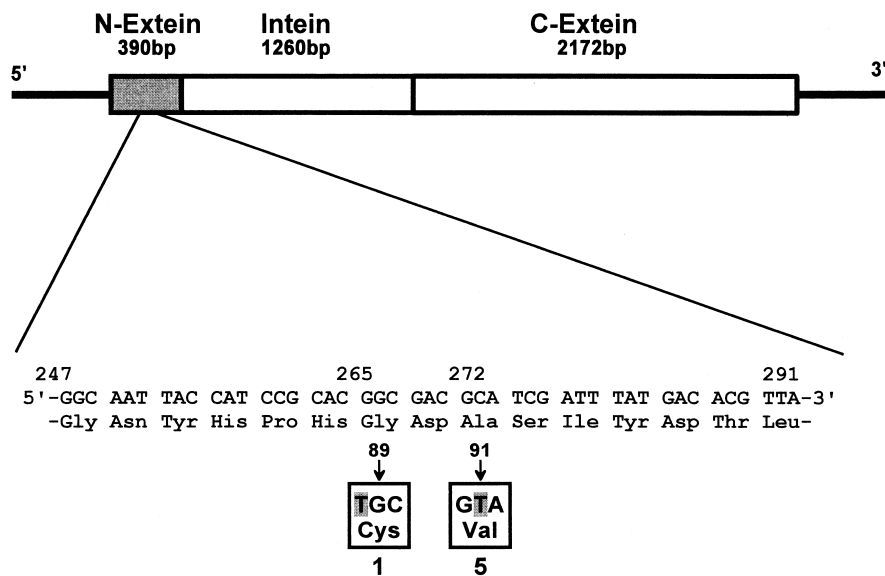

FIG. 3. Structure and nucleotide sequence of the *gyrA* gene from clinical isolates of *M. leprae*. To analyze the sequence, the *gyrA* sequence from positions 1 to 390 was amplified by PCR. Mutations at positions 89 and 91 were found in ofloxacin-resistant *M. leprae*. The numbering system of reference 1 was used.
