ABSTRACT

Background

Head injury is a common event and can cause a spectrum of motor and cognition disabilities. A frequent complication is seizures. Antiepileptic drugs (AED) such as phenytoin are often used in clinical practice with the hopes of preventing post-traumatic epilepsy. Whether immediate medical intervention following head trauma with either AEDs or neuroprotective drugs can alter the process of epileptogenesis and lead to a more favorable outcome is currently unknown. This review attempted to address the effectiveness of these treatment interventions. This review updates and expands on the earlier Cochrane review.

Objectives

To compare the efficacy of antiepileptic drugs and neuroprotective agents with placebo, usual care or other pharmacologic agents for the prevention of post-traumatic epilepsy in people diagnosed with any severity of traumatic brain injury.

Search methods

We searched The Cochrane Epilepsy Group's specialized register, CENTRAL, MEDLINE, ClinicalTrials.gov and World Health Organization International Clinical Trials Registry Platform (ICTRP) in January 2015. We searched EMBASE, Biological Abstracts and National Research Register in September 2014 and SCOPUS in December 2013. The Cochrane Epilepsy Group performed handsearches of relevant journals.

Selection criteria

We included randomized controlled trials (RCTs) that include AEDs or neuroprotective agents compared with placebo, another pharmacologic agent or a usual care group. The outcomes measured included a seizure occurring within one week of trauma (early seizure), seizure occurring later than one week post-trauma (late seizure), mortality and any adverse events.

Data collection and analysis

Two review authors independently assessed study quality and extracted the data. We calculated risk ratios (RR) and 95% confidence intervals (CI) for each outcome. We used random-effects models in the meta-analyses and performed pre-defined subgroup and sensitivity analyses.

Main results

This review included 10 RCTs (reported in 12 articles) consisting of 2326 participants. The methodological quality of the studies varied. The type of intervention was separated into three categories; AED versus placebo or standard care, alternative neuroprotective agent versus placebo or standard care and AED versus other AED. Treatment with an AED (phenytoin or carbamazepine) decreased the risk of early seizure compared with placebo or standard care (RR 0.42, 95% CI 0.23 to 0.73; very low quality evidence). There was no evidence of a difference in the risk of late seizure occurrence between AEDs and placebo or standard care (RR 0.91, 95% CI 0.57 to 1.46; very low quality evidence). There was no evidence of a significant difference in all-cause mortality between AEDs and placebo or standard care (RR 1.08, 95% CI 0.79 to 1.46, very low quality of evidence). Only one study looked at other potentially neuroprotective agents (magnesium sulfate) compared with placebo. The risk ratios were: late seizure 1.07 (95% CI 0.53 to 2.17) and all-cause mortality 1.20 (95% CI 0.80 to 1.81). The risk ratio for occurrence of early seizure was not estimable.

Two studies looked at comparison of two AEDs (levetiracetam, valproate) with phenytoin used as the main comparator in each study. The risk ratio for all-cause mortality was 0.53 (95% CI 0.30 to 0.94). There was no evidence of treatment benefit of phenytoin compared with another AED for early seizures (RR 0.66, 95% CI 0.20 to 2.12) or late seizures (RR 0.77, 95% CI 0.46 to 1.30).

Only two studies reported adverse events. The RR of any adverse event with AED compared with placebo was 1.65 (95% CI 0.73 to 3.66; low quality evidence). There were insufficient data on adverse events in the other treatment comparisons.

Authors' conclusions

This review found low-quality evidence that early treatment with an AED compared with placebo or standard care reduced the risk of early post-traumatic seizures. There was no evidence to support a reduction in the risk of late seizures or mortality. There was insufficient evidence to make any conclusions regarding the effectiveness or safety of other neuroprotective agents compared with placebo or for the comparison of phenytoin, a traditional AED, with another AED.

PLAIN LANGUAGE SUMMARY

Medicines for preventing epilepsy following traumatic head injury

Background

Traumatic head injury is a frequent event and can injure the brain. This severe injury is often followed by seizures (fits), which may worsen the damage and can lead to chronic epilepsy, a neurologic disorder characterized by frequent recurrent seizures. Antiepileptic drugs are usually given to suppress already diagnosed seizures. Their role in curing the disease and preventing the development of epilepsy in people who are considered at risk for seizures after any brain injury, including head trauma, is not well understood.

Study characteristics

We searched for studies evaluating the effect of early administration of antiepileptic drugs or other potentially neuroprotective agents (which act by protecting the structure or function of nerves) on post-traumatic epilepsy. The primary outcomes of interest were early post-traumatic seizures (within one week of trauma) and late seizures (later than one week post-trauma). We also looked at death, time to late seizure and side effects. The evidence is current to January 2015.

Key results

We found 10 clinical trials involving 2326 people reported in 12 published articles. The evidence available indicated that early treatment with a traditional antiepileptic drug (phenytoin or carbamazepine) may reduce the risk of early post-traumatic seizures. Traditional antiepileptic drugs are no more effective than placebo (a pretend pill) or standard care in reducing late seizures or mortality. Limited data were available for the comparison of an AED with another AED and for the comparison of other potentially neuroprotective agents with placebo. Most studies did not report serious side effects and other side effects.

Quality of the evidence

The overall quality of the evidence varied and findings should be interpreted with caution.

SUMMARY OF FINDINGS

Summary of findings for the main comparison. Antiepileptic drugs compared with placebo or standard care for people at risk of epilepsy following traumatic head injury

Antiepileptic drugs compared with placebo or standard care for people at risk of epilepsy following traumatic head injury

Patient or population: people with traumatic head injuries

Settings: Neurosurgery departments, ICU and trauma centers in North America, UK and Europe

Intervention: antiepileptic drugs

Comparison: placebo or standard care

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Placebo or standard care	Antiepileptic drugs				
Early seizures Count of events Follow-up: 5-7 days	139 per 1000	59 per 1000 (32 to 102)	RR 0.42 (0.23 to 0.74)	987 (5 studies)	⊕⊕⊕⊕ low 1,2	Sensitivity analysis by quality of the study shows that RR for early seizures in low/unclear risk studies was no longer significant (RR 0.59, 95% CI 0.20 and 1.73)
Late seizures Count of events Follow-up: 3-24 months	178 per 1000	162 per 1000 (100 to 260)	RR 0.91 (0.57 to 1.46)	1029 (6 studies)	⊕⊕⊕⊕ very low 3,4,5	RR of late seizures remained insignificant regardless of type of antiepileptic drug, treatment duration, age of population or quality of the study
All-cause mortality Follow-up: 5 days to 24 months	174 per 1000	188 per 1000 (138 to 255)	RR 1.08 (0.79 to 1.46)	1065 (5 studies)	⊕⊕⊕⊕ very low 1,4,5	RR for all-cause mortality remained insignificant regardless of treatment duration, age of population or quality of the study
Any serious adverse event of treatment count of events Follow up: 12 months	94 per 1000	154 per 1000 (69 to 345)	RR 1.63 (0.73 to 3.66)	568 (2 studies)	⊕⊕⊕⊕ low 5,6	
Time to first seizure from randomization	See comment	See comment	Not estimable	0 (0 studies)	See comment	No study reported time to first seizure in an interpretable way

*The basis for the **assumed risk** is the event rate in the control (placebo or standard care) group. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: confidence interval; **RR:** risk ratio.

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

¹ Downgraded one level due to serious risk of bias: Two studies included in this outcome had instances of high risk of bias assessment. The remaining studies had a mix of low and unclear risk of bias.

² Downgraded one level due to imprecision: RR for early seizures by study was inconsistent and ranged from 0.24 to 1.22. The difference in risk tends to be associated with differences in risk of bias between studies.

³ Downgraded one level due to serious risk of bias: Four studies included in this outcome had one to four instances of high risk in risk of bias assessment. The remaining two studies had a mix of low and unclear risk of bias.

⁴ Downgraded one level due to inconsistency of results ($I^2=54%$): Some heterogeneity may be explained by study design, population, intervention (dose) or follow-up. However, there is wide variation in the results showing both considerable harm and considerable benefit.

⁵ Downgraded one level due to imprecision of results: wide 95% CI that includes both considerable harm and benefit.

⁶ Downgraded one level due to serious risk of bias: selection bias was likely in both trials

Summary of findings 2. Neuroprotective agent versus placebo for people at risk of epilepsy following traumatic head injury

Neuroprotective agents compared with placebo for people at risk of epilepsy following traumatic head injury

Patient or population: people with traumatic head injuries

Settings: Neurosurgery departments, ICU and trauma centers in North America, UK and Europe

Intervention: Neuroprotective agents

Comparison: Placebo

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				
	Placebo	Neuroprotective agents				
Early seizure Count of events Follow-up: 7 days	0 per 1000	0 per 1000 (0 to 0)	RR 2.99 (0.12 to 73.00)	499 (1 study)	⊕⊕⊕⊕ low ^{1,2}	No events occurred in the control group therefore corresponding risk is also zero

Late seizure	56 per 1000	60 per 1000 (30 to 122)	RR 1.07 (0.53 to 2.17)	498 (1 study)	⊕⊕⊕⊕ high	
Count of events						
Follow-up: 6 months						
All-cause mortality	150 per 1000	180 per 1000 (120 to 272)	RR 1.20 (0.80 to 1.81)	466 (1 study)	⊕⊕⊕⊕ high	
Follow-up: 6 months						
Any serious adverse event of treatment	See comment	See comment	Not estimable	0 (0 studies)	See comment	No study reported adverse event data
Time to first seizure from randomization	See comment	See comment	Not estimable	0 (0 studies)	See comment	No study reported time to first seizure in an interpretable way

*The basis for the **assumed risk** is the event rate in the control (placebo or standard care) group. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: confidence interval; **RR:** risk ratio.

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

¹ Downgraded one level due to risk of bias: As reported in the study paper, 96% of participants received phenytoin for the first week in both treatment groups. This may have resulted in a very low early seizure rate

² Downgraded one level due to imprecision of results: wide 95% CI that includes both considerable harm and benefit.

Summary of findings 3. Anti-epileptic drugs compared to other anti-epileptic drugs for people at risk of epilepsy following traumatic head injury

Anti-epileptic drugs compared to other anti-epileptic drugs for people at risk of epilepsy following traumatic head injury

Patient or population: people with traumatic head injuries

Settings: Neurosurgery departments, ICU and trauma centers in North America, UK and Europe

Intervention: Phenytoin

Comparison: Other anti-epileptic drugs (AEDs)

Outcomes	Illustrative comparative risks* (95% CI)		Relative effect (95% CI)	No of Participants (studies)	Quality of the evidence (GRADE)	Comments
	Assumed risk	Corresponding risk				

	Other AEDs	Phenytoin				
Early seizure Counts of events Follow up: 7 days	57 per 1000	38 per 1000 (11 to 121)	RR 0.66 (0.20 to 2.12)	431 (2 studies)	⊕⊕⊕○ low^{1,2}	
Late seizure Counts of events Follow up: 6 months to 2 years	166 per 1000	128 per 1000 (76 to 216)	RR 0.77 (0.46 to 1.30)	378 (2 studies)	⊕⊕⊕○ moderate¹	
All-cause mortality Follow up: 6 months to 2 years	164 per 1000	87 per 1000 (49 to 154)	RR 0.53 (0.30 to 94)	431 (2 studies)	⊕⊕⊕○ moderate¹	
Any serious adverse event of treatment	See comment	See comment	Not estimable	0 (0 studies)	See comment	No study reported adverse event data
Time to first seizure from randomization	See comment	See comment	Not estimable	0 (0 studies)	See comment	No study reported time to first seizure in an interpretable way

*The basis for the **assumed risk** is the event rate in the control (placebo or standard care) group. The **corresponding risk** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).
CI: confidence interval; **RR:** risk ratio.

GRADE Working Group grades of evidence

High quality: Further research is very unlikely to change our confidence in the estimate of effect.

Moderate quality: Further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.

Low quality: Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low quality: We are very uncertain about the estimate.

¹ Downgraded one level due to risk of bias; unclear information reported in one study regarding study design (randomisation and blinding) and loss to follow up from the study

² Downgraded one level due to imprecision of results: wide 95% CI that includes both considerable harm and benefit.

BACKGROUND

Description of the condition

Head injury is a common event and can cause a spectrum of motor and cognition disabilities. A frequent complication is seizures. While 'early seizures' are frequently considered to be nonspecific diffuse reactions as a result of an acute encephalopathy and are self limited, seizures following several weeks or months after head trauma seem to reflect an underlying process of post-traumatic scar formation and epileptogenesis. However, there is evidence from epidemiologic studies that early seizures can be predictors for late seizures (Wyllie 2010). This suggests that these definitions reflect simplifications of the underlying ongoing tissue transformation over time. The risk for late 'unprovoked' seizure recurrence increases with the severity of the injury, involvement of the cerebral cortex, presence of dura penetration, skull fracture and intracerebral hematoma, and the occurrence of early seizures (Jennett 1981; Annegers 1998). Timing and the interplay of potentially involved factors in the development of this epileptogenic process are unclear.

Description of the intervention

Behind the concept of preventing post-traumatic epilepsy stands the hope that the silent period of weeks and months after the trauma, before seizure occurrence, is a window of opportunity to stop the process using appropriate interventional treatment strategies (Temkin 2009). Antiepileptic drugs (AEDs) can suppress seizures; however, it is the subject of a controversial debate if they are also able to interfere positively with the process leading to epilepsy. Experimental studies looking at neuroprotective agents, such as antioxidants and free radicals, have also been promising but historically have not translated well into the clinical environment (Slemmer 2008). Therefore, this Cochrane review will carefully evaluate the impact of either early or late use of AEDs and neuroprotective agents on the occurrence of unprovoked seizures following the trauma.

How the intervention might work

Current experimental epilepsy research using animal models, such as kindling and post-status epileptic condition, suggests that some new AEDs may have the potential to alter the underlying epileptogenic process and act as disease-modifying agents (Löscher 2002; Brandt 2006). There is also some evidence that neuroprotective agents may alter the epileptogenic process. For example, antioxidants may be able to suppress this process by interfering with free radical reactions initiated by hemorrhage associated with brain injuries (Willmore 2009).

Why it is important to do this review

Post-traumatic seizures are quite prevalent. Most of these people undergo a careful functional and structural diagnostic algorithm including electroencephalography (EEG) and magnetic resonance imaging (MRI) or at least computed tomography (CT). Therefore, post-traumatic seizures can be considered an ideal model to study tissue changes and regional hyperexcitability as part of the evolving epileptogenic scar. It is not yet known whether immediate medical intervention following head trauma with either AEDs or neuroprotective drugs can alter the process of epileptogenesis and lead to a more favorable outcome. There are limited data on

traditional AEDs such as phenytoin, phenobarbital, valproate and carbamazepine.

With the advent since the mid-2000s of many new AEDs and research into alternative treatments such as neuroprotective agents, it seems critical and timely to review the human experience carefully and evaluate how these experimental findings might translate into the prevention of post-traumatic epilepsy in clinical practice. Therefore, this review will conduct a systematic, up-to-date review of randomized controlled trials (RCTs) examining the effectiveness and safety of both AEDs and neuroprotective agents with special focus on recently licensed products.

OBJECTIVES

To compare the efficacy of antiepileptic drugs and neuroprotective agents with placebo, usual care or other pharmacologic agents for the prevention of post-traumatic epilepsy in people diagnosed with any severity of traumatic brain injury.

METHODS

Criteria for considering studies for this review

Types of studies

RCTs that included AEDs or neuroprotective agents compared with placebo, another pharmacologic agent or a usual care group. We included studies published in any languages. We excluded quasi-randomized studies, dose-finding studies and cluster randomized or cross-over trials.

Types of participants

People of all ages diagnosed with acute traumatic brain injury (TBI) who received prophylactic treatment with AEDs or neuroprotective agents. Administration was post-injury and prior to the occurrence of a first post-traumatic seizure (FPS). We excluded people with previously documented unprovoked seizures.

Types of interventions

Treatment

- Any conventional AED post-injury and prior to the occurrence of an FPS. Traditional AEDs included, but were not limited to, carbamazepine, phenytoin and valproate, and examples of new AEDs included but were not limited to oxcarbazepine, lamotrigine, levetiracetam and topiramate.
- Any alternative neuroprotective pharmacologic treatments, including administration of distinct neurotrophic factors, hormones or antioxidants post-injury and prior to the occurrence of an FPS.

Comparison

Other pharmacologic agent, placebo or usual care.

- Pharmacologic agents (AED) versus placebo or usual care.
- Neuroprotective agent versus placebo or usual care.
- Pharmacologic agent A (AED) versus pharmacologic agent B (AED).

We analyzed each comparison separately.

Types of outcome measures

Primary outcomes

- Proportion of participants who experience an early seizure post-trauma, defined as occurring within one week of trauma.
- Proportion of participants who experience a late seizure post-trauma, defined as occurring later than one week post-trauma.

Secondary outcomes

- Mortality from any cause during follow-up period.
- Time to first seizure from randomization.
- Proportion of participants experiencing serious treatment-related adverse events.

Search methods for identification of studies

Electronic searches

We searched the following databases:

- Cochrane Epilepsy Group Specialized Register (latest search date: 13 January 2015) using the search strategy given in [Appendix 1](#);
- Cochrane Central Register of Controlled Trials (CENTRAL) via Cochrane Register of Studies Online (CRSO), latest search date: 13 January 2015, using the search strategy given in [Appendix 2](#);
- MEDLINE (OVID; 1946 to 13 January 2015) using the search strategy given in [Appendix 3](#);
- EMBASE (Elsevier; latest search date: 5 September 2014) using the search strategy given in [Appendix 4](#);
- [ClinicalTrials.gov](#) and [World Health Organization \(WHO\) International Clinical Trials Registry Platform \(ICTRP\)](#) searched on 13 January 2015 for 'traumatic head injury AND epilepsy';
- SCOPUS (1823 to 17 December 2013) using the search strategy given in [Appendix 5](#);
- Biological Abstracts (latest search date: 5 September 2014) using the search strategy given in [Appendix 6](#).

The electronic search strategy used in the review by [Schierhout 2001](#) was expanded upon.

It is no longer necessary to search SCOPUS or EMBASE, because RCTs listed in EMBASE are now included in CENTRAL, and SCOPUS is a substitute for EMBASE.

Searching other resources

In addition to searching electronic databases, we consulted the following sources.

- Bibliographies of related Cochrane reviews.
- Reference sections of included papers and key systematic reviews ([Temkin 2001](#); [Beghi 2003](#)).
- Authors of relevant reports regarding any further published or unpublished work.
- National Research Register.
- Handsearching of content related journals as conducted by The Cochrane Epilepsy Group.

Data collection and analysis

Selection of studies

Two review authors independently reviewed titles and abstracts obtained from the literature search. Review authors then ranked each as follows.

- Include: study met criteria.
- Unclear: insufficient to determine if study met criteria.
- Exclude: study did not meet criteria.

The review authors compared and discussed results; a third review author arbitrated any disagreements. We excluded papers where insufficient evidence was available in a study. If necessary, we contacted authors for further clarification. When multiple publications of the same study were found, we included the original study that met the inclusion criteria; we included the second study if it contained different outcomes. We placed no language or time restriction on included studies.

Data extraction and management

We used the full text to include or exclude studies where it was unclear from reading the abstracts. Two review authors independently extracted data from included RCTs in the following categories.

- Participant characteristics:
 - inclusion and exclusion criteria;
 - number of participants per group;
 - age;
 - sex;
 - trauma characteristics such as severity, MRI or CT documented pattern of injury,
 - EEG findings.
- Methods:
 - study design;
 - duration of study;
 - randomization method;
 - treatment allocation;
 - completeness of follow-up;
 - presence of blinding;
 - intention-to-treat (ITT) analysis.
- Intervention:
 - type of agent, treatment 1, treatment 2 or control;
 - method of administration;
 - dosage and duration of treatment;
 - time post-trauma treatment was delivered;
 - control or usual care intervention.
- Outcome measures and clinical findings:
 - seizure occurrence;
 - mortality;
 - number of seizures;
 - time to first seizure;
 - adverse events;
 - neurologic findings.
- Possible sources of heterogeneity:

- median age of participant at time of injury;
- severity of trauma;
- pharmacologic agent;
- duration of treatment;
- timing of treatment.
- Other:
 - country and setting of study;
 - year of publication;
 - title;
 - authors.

We used a predefined form for this task ([Appendix 7](#)).

The form was developed and pilot tested on three trials prior to use on all studies.

Assessment of risk of bias in included studies

Two review authors independently assessed the quality of studies. Methods used for summary assessment are provided in the *Cochrane Handbook for Systematic Reviews of Interventions* 5.1, Section 8.4 ([Higgins 2011](#)). We scored each of the following domains as at 'high', 'low' or 'unclear' risk and reported the scores in the 'Risk of bias' table.

- Selection bias:
 - sequence generation;
 - allocation of concealment.
- Performance bias:
 - blinding of participants and personnel;
 - other potential threats to validity.
- Detection bias:
 - blinding of outcome assessment;
 - other potential threats to validity.
- Attrition bias:
 - incomplete outcome data.
- Reporting bias:
 - selective outcome reporting.
- Other bias

Measures of treatment effect

We performed statistical analyses and produced a summary of the data using Review Manager 5 ([RevMan 2012](#)). We presented dichotomous outcomes as risk ratios (RR) with corresponding 95% confidence intervals (CI). We planned to present time-to-event outcomes as hazard ratios with 95% CI. If hazard ratios were not given, we planned to use indirect estimation methods ([Parmar 1998](#); [Williamson 2002](#)). None of the included studies presented time-to-event data; we therefore did not summarize results using hazard ratios. For individual listed adverse effects, we quoted 99% CIs, making an allowance for multiple testing. We performed separate analyses for each control group. We used an ITT analysis on outcomes from all randomized participants where possible for primary analyses.

Unit of analysis issues

The unit of analysis for this review was the individual participant

Dealing with missing data

We contacted authors where substantial outcomes of interest were not reported or to clarify uncertainty about study characteristics. We waited one month for a response from authors, after which time we formally considered data to be missing.

ITT analyses were performed.

Assessment of heterogeneity

We used forest plots to assess the statistical heterogeneity of studies visually and the Chi² test to assess evidence of heterogeneity. We used a P value < 0.1 to determine statistical significance ([Whitehead 1991](#)). We calculated the I² statistic with I² values greater than 50% indicating substantial to considerable heterogeneity ([Higgins 2011](#)). If we found values of heterogeneity greater than 50%, we attempted to explain the heterogeneity based on the differences in study characteristics and participant profiles (such as severity of trauma, age).

Assessment of reporting biases

We planned to assess publication bias using funnel plots if more than 10 studies were included. Reasons for funnel plot asymmetry include publication bias, outcome reporting bias, language bias, citation bias, poor methodologic design and heterogeneity. We assessed these for each trial, where possible. We planned to include an ORBIT table to explore the impact of selective outcome reporting further ([Kirkham 2010](#)). We found few studies assessing each of the pre-specified outcomes; we therefore did not prepare funnel plots or orbit tables

Data synthesis

To pool the data for each outcome, we used the random-effects method ([DerSimonian 1986](#)) based on the inverse variance method, rather than using a fixed effects method. A random-effects model meta-analysis involves an assumption that the effects being estimated in the different studies are not identical but follow the same distribution ([Higgins 2011](#)). Summary intervention estimates are a weighted mean of the estimate from each individual study. A fixed-effect model was considered as a sensitivity analysis.

'GRADEing' the evidence

We followed the recommended GRADE approach to assess the quality of the evidence for each outcome. We produced 'Summary of findings' tables for each treatment comparison for the primary outcomes (early seizure and late seizure) and secondary outcomes (all cause mortality, time to first seizure from randomisation and proportion of participants experiencing serious treatment-related adverse events) based on established recommendations ([Schünemann 2011](#)).

Subgroup analysis and investigation of heterogeneity

We intended to evaluate clinical and methodologic heterogeneity across studies by comparing the characteristics of participants, interventions and study designs.

We performed the following clinically relevant subgroup analyses to investigate possible sources of clinical heterogeneity.

- Mean age of participants in study at time of injury: adults (ages over 17 years), school age children (ages six to 17 years) and children (ages under six years).
- Pharmacologic agent: recently licensed AEDs and traditional AEDs.
- Severity of trauma: minor, moderate and severe TBI. This review followed the paper by [Teasell 2007](#) for classification of head trauma ([Appendix 8](#)).
- Duration of treatment: short-term treatment (treatment less than three months post-injury), mid-term treatment (more than three months and less than 12 months post-injury) and long-term treatment (any duration longer than one year post-injury).

Tests of Interaction (Cochran's Q and Higgins I²) for subgroup differences were performed. Data were not available for all the pre-planned subgroup analysis (see [Differences between protocol and review](#)).

Sensitivity analysis

We performed sensitivity analysis to evaluate the robustness of decisions made in the review methodology.

- Study quality: excluding studies which were high risk of bias
- Age range of participants: analysis repeated excluding those studies where it was not possible to separate participants that did not meet the inclusion criteria for age.

RESULTS

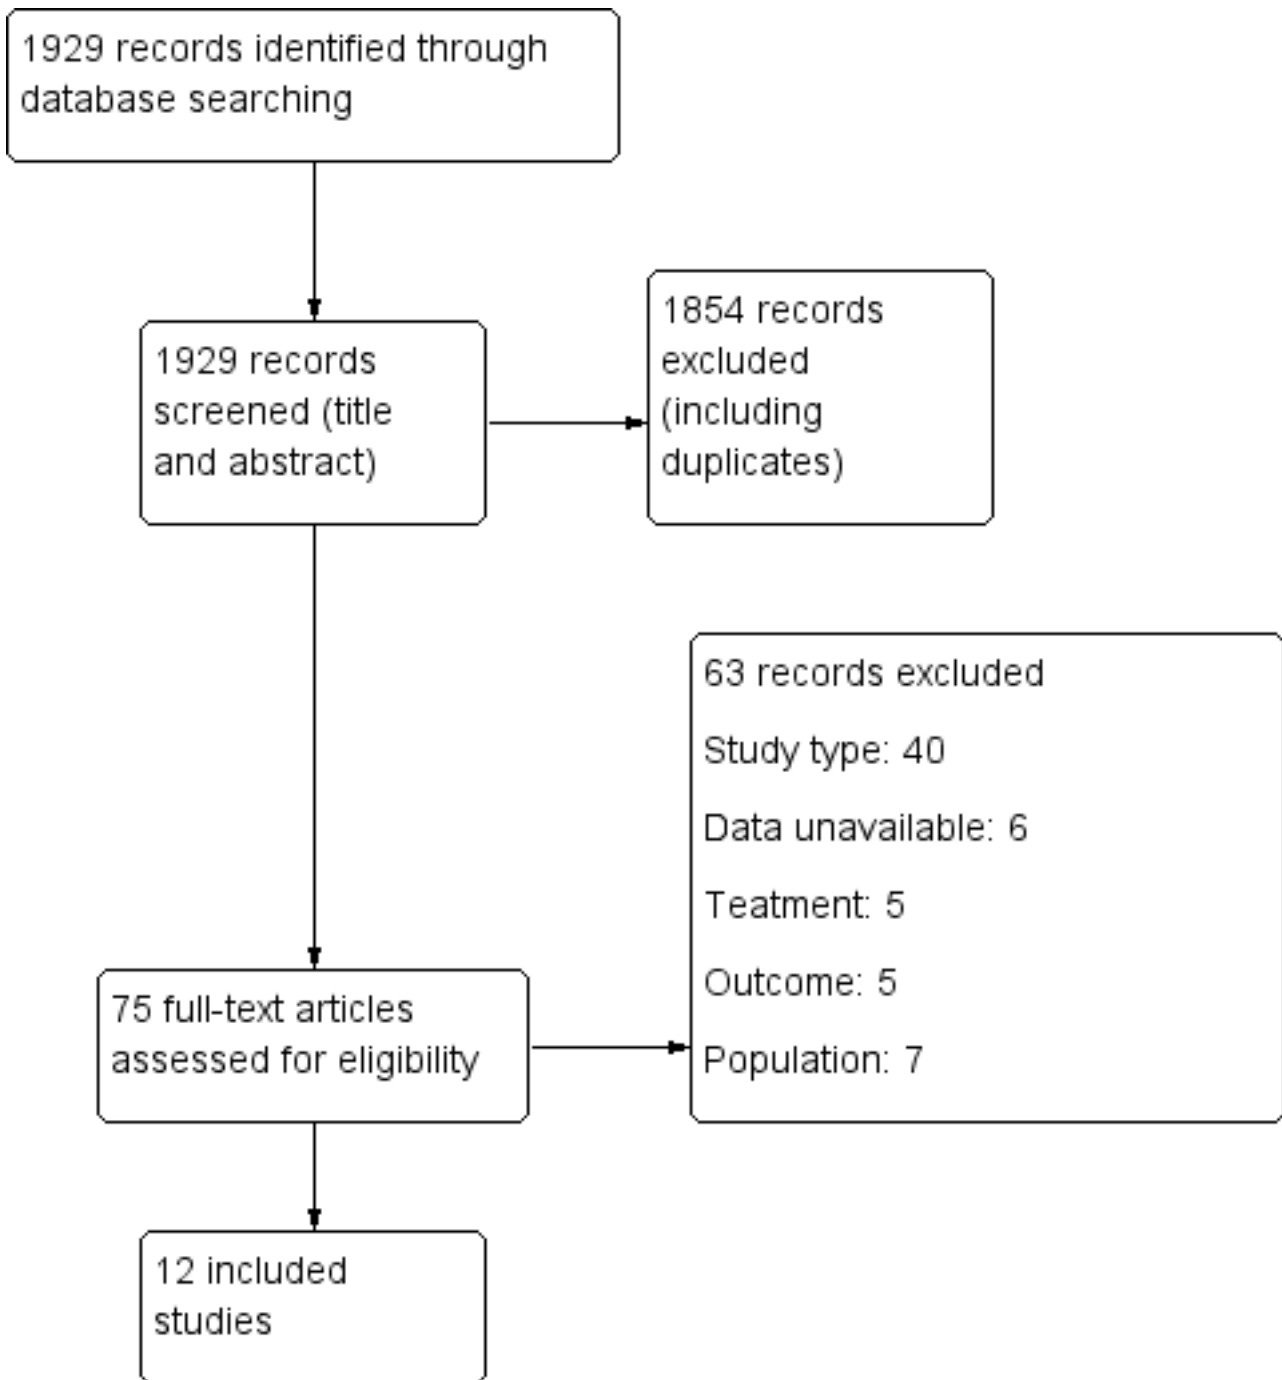

Description of studies

See: [Characteristics of included studies](#); [Characteristics of excluded studies](#).

Results of the search

Of the 1929 initial citations identified, we screened 75 reports (See [Figure 1](#)).

Figure 1. Study flow diagram.

Included studies

Ten RCTs described in 12 published articles met review inclusion criteria and included 2326 randomized participants ages five years and older. All trials included participants with moderate and severe TBI and excluded people with pre-existing epilepsy.

Five trials included children (McQueen 1983; Young 1983; Pechadre 1991; Manaka 1992; Young 2004). Young 2004 included only children under the age of 10 years.

Six trials reported on short-term treatments (five to seven days to one month) (Young 1983; Pechadre 1991; Temkin 1999; Young 2004; Temkin 2007; Szaflarski 2010), three reported on mid-term treatments (six to 12 months) (McQueen 1983; Temkin 1990; Temkin 1999), and three trials reported on long-term treatments (18 months to two years) (Glotzner 1983; Young 1983; Manaka 1992). Most studied traditional AEDs versus placebo or usual care: phenytoin (McQueen 1983; Young 1983; Temkin 1990; Pechadre 1991; Young 2004), phenobarbital (Manaka 1992), carbamazepine (Glotzner 1983), and valproate (Temkin 1999); one studied a newly licensed agent: levetiracetam versus phenytoin (Szaflarski 2010),

and one studied an 'other' agent, magnesium sulfate (MgSO₄) versus placebo (Temkin 2007).

Six trials were conducted in the USA (Young 1983; Temkin 1990; Temkin 1999; Young 2004; Temkin 2007; Szaflarski 2010), three in Europe (Glotzner 1983; McQueen 1983; Pechadre 1991), and one in Japan (Manaka 1992).

We included nine trials in the meta-analysis and assessed the primary and secondary outcomes of early seizures, late seizures, all-cause mortality and adverse events (Glotzner 1983; McQueen 1983; Young 1983; Temkin 1990; Pechadre 1991; Manaka 1992; Temkin 1999; Young 2004; Szaflarski 2010). All but two trials reported incidence of early and late seizures; Manaka 1992 and McQueen 1983 reported only late seizures. All trials but Manaka 1992 and Pechadre 1991 reported mortality. The majority of trials primarily investigated whether AEDs (traditional or newly licensed) prevented early or late (or both) seizure occurrence in people with TBI. One trial primarily investigated safety and reported on adverse events (Szaflarski 2010). McQueen 1983 and Temkin 1990 also reported the occurrence of skin rashes. Temkin 2007 was not included in a meta-analysis as it was the only study included in the

review that studied an 'other' agent. See [Characteristics of included studies](#) table for details.

Excluded studies

We excluded 63 studies from the review. Forty were not RCTs or quasi-randomized trials, in seven the data were unavailable (i.e. trial cancelled due to lack of enrolment or unable to acquire details from author), four studies were secondary publications of studies already included, which contained no further relevant information. Five studies did not report treatment of interest, seven did not include the population of interest. See [Characteristics of excluded studies](#) table for details.

Risk of bias in included studies

Figure 2 and Figure 3 summarize the risk of bias of included studies. We deemed no study to be at low risk of bias in all bias types. The majority of studies had a mix of low and unclear bias to varying degrees. Five trials had a number of bias types classified as high risk of bias (Glotzner 1983; McQueen 1983; Young 1983; Pechadre 1991; Manaka 1992).

Figure 2. Risk of bias graph: review authors' judgments about each risk of bias item presented as percentages across all included studies.

Figure 3. Risk of bias summary: review authors' judgments about each risk of bias item for each included study.

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)
Glotzner 1983	?	?	+	-	-	?	?
Manaka 1992	?	?	-	-	-	?	?
McQueen 1983	+	+	+	+	-	+	+
Pechadre 1991	-	?	?	-	?	-	-
Szaflarski 2010	?	+	?	+	?	?	+
Temkin 1990	?	?	+	+	+	+	+
Temkin 1999	+	+	?	?	+	+	+
Temkin 2007	+	+	?	?	?	+	+
Young 1983	?	?	?	-	?	+	?
Young 2004	+	+	+	+	?	+	?

Allocation

Only three trials adequately described the sequence generation and allocation process (Temkin 1999; Young 2004; Temkin 2007). Szaflarski 2010 indicated the participants were randomized by the pharmacy but did not describe the sequence generation and, therefore, the risk of selection bias was unclear. Risk of selection bias was unclear in McQueen 1983; Young 1983; Temkin 1990; Manaka 1992, due to lack of clear description of the sequence generation and allocation process. The sequence generation in Glotzner 1983 and Pechadre 1991 was based on odd/even birthday or days of admission and, therefore, at high risk of predicting group allocation.

Blinding

Six of the 10 trials were low risk for performance bias as they adequately described blinding of participants and personnel (McQueen 1983; Young 1983; Temkin 1990; Temkin 1999; Young 2004; Temkin 2007). In Glotzner 1983; Manaka 1992; and Szaflarski 2010, risk of bias for performance bias was unclear as these trials did not report on blinding of participants and personnel. Risk of detection bias was low in five trials (McQueen 1983; Temkin 1990; Temkin 1999; Temkin 2007; Szaflarski 2010), and unclear in four publications as they did not describe blinding of the outcome assessment (Glotzner 1983; Young 1983; Manaka 1992; Young 2004). Pechadre 1991 was at high risk for performance and detection bias as it did not describe blinding of the participants, personnel or outcome assessment and the predictable randomization process suggested that assessors could easily determine which participants were allocated to treatment and control groups.

Incomplete outcome data

Three trials were low risk for attrition bias as they clearly described outcome data and attrition patterns (McQueen 1983; Temkin 1990; Young 2004). Six trials had unclear risk for attrition bias due to poor descriptions of reasons for attrition (Glotzner 1983; Young 1983; Pechadre 1991; Temkin 1999; Temkin 2007; Szaflarski 2010), and Manaka 1992 was high risk of bias for lack of description or details on 52 people who were excluded or dropped out from study.

Selective reporting

Only four of the 10 trials were low risk for reporting bias (McQueen 1983; Temkin 1990; Young 2004; Szaflarski 2010). Four trials were at high risk of selective reporting as they did not report adverse events (Glotzner 1983; Young 1983; Pechadre 1991; Manaka 1992). In addition, Manaka 1992 and Pechadre 1991 did not report mortality and Young 1983 reported mortality inconsistently across age groups. Young 1983 reported mortality as a count of events for all ages in the short-term treatment; however, mortality in adults on long-term treatment were not reported as a count of events and, therefore, overall deaths for the entire trial were underestimated. Manaka 1992 was high risk for reporting bias as the trial did not report baseline characteristics. The remaining two trials had unclear risk (Temkin 1999; Temkin 2007).

Other potential sources of bias

Three publications were at high risk for other types of bias (Glotzner 1983; McQueen 1983; Manaka 1992). Glotzner 1983 reported that the majority of participants received an AED in the first week regardless of allocation group resulting in potential contamination of controls. McQueen 1983 reported potential significant baseline

differences between the control and treatment groups with more five to 15 year olds in the treatment group and below therapeutic levels of the phenytoin were reported. Manaka 1992 did not report baseline characteristics, so it was impossible to compare baseline characteristics between treatment groups. Several studies reported difficulties with compliance (McQueen 1983; Young 1983; Temkin 1990; Temkin 1999), and maintaining therapeutic levels particularly when evaluating late seizure outcome.

Effects of interventions

See: **Summary of findings for the main comparison** Antiepileptic drugs compared with placebo or standard care for people at risk of epilepsy following traumatic head injury; **Summary of findings 2** Neuroprotective agent versus placebo for people at risk of epilepsy following traumatic head injury; **Summary of findings 3** Anti-epileptic drugs compared to other anti-epileptic drugs for people at risk of epilepsy following traumatic head injury

1. Antiepileptic drug versus placebo or usual care

1.1 Occurrence of early seizure

Five trials involving 987 participants examined the occurrence of early seizures (Glotzner 1983; Pechadre 1991; Temkin 1990; Young 2004; Young 1983). All trials compared a traditional AED (carbamazepine or phenytoin) with a placebo or usual care. The trials included a range of ages from children to adult. Duration of treatment for this outcome varied from five to seven days. The proportion of participants experiencing an early seizure in the treatment group was 5.0% (25/499) compared with 13.9% (68/488) in the placebo group/usual care group. The pooled results favored the traditional AED treatment compared with the control group (RR 0.42, 95% CI 0.23 to 0.73; **Analysis 1.1**). Heterogeneity was low among the studies ($I^2 = 29\%$). We reanalyzed the outcome using fixed-effect methods; results were consistent with those obtained using random-effects models. We rated the quality of the evidence as low due to high selective reporting bias in 3 of the studies and inconsistency in RR results in the two studies with low risk of bias (**Analysis 1.7**).

1.2 Occurrence of late seizure

Six trials reported on late seizures in 1029 participants (Glotzner 1983; McQueen 1983; Young 1983; Temkin 1990; Pechadre 1991; Manaka 1992). Manaka 1992 compared phenobarbital with usual care, Glotzner 1983 compared carbamazepine with placebo, while the other four trials compared phenytoin with placebo. Duration of treatment varied from three months to two years. Five of the six trials included adults and children; Temkin 1999 was the only trial to assess adults exclusively. About 15.6% (81/518) of participants receiving AED treatment experienced a late seizure compared with 17.8% (91/511) receiving placebo/usual care. The six-pooled studies showed no statistically significant effect for traditional AEDs compared with placebo or usual care on late seizure occurrence (RR 0.91, 95% CI 0.57 to 1.467; **Analysis 1.2**). There was evidence of heterogeneity among the studies ($I^2 = 54\%$). This result was rated as very low quality due to high risk of bias in 2 or more categories for several studies, imprecision of pooled RR estimate and moderate level of heterogeneity.

1.3 All-cause mortality

Five trials reported mortality in 1065 participants (Glotzner 1983; McQueen 1983; Young 1983; Temkin 1990; Young 2004). They

compared a traditional AED (carbamazepine or phenytoin) with placebo. Duration of treatments varied from five days to 24 months. About 18.4% (101/549) of participants in the AED group died compared with 17.4% (90/516) in the placebo group. The five pooled trials showed no statistically significant difference in the RR of death between participants treated with traditional AEDs compared with placebo (RR 1.08, 95% CI 0.79 to 1.46; [Analysis 1.3](#)). Heterogeneity was low among the studies ($I^2 = 19\%$). This result was rated as very low quality due to high risk of bias in 2 or more categories for several studies, imprecision of pooled RR estimate with confidence interval ranging from benefit to harm.

1.4 Any serious event

[McQueen 1983](#) and [Temkin 1990](#) looked at any serious events comparing phenytoin with placebo. About 14.4% (42/292) of participants in treatment group experienced an adverse event compared with 9.4% (26/276) in the placebo group. The pooled RR of an adverse event in treatment group compared with placebo was 1.63 (95% CI 0.73 to 3.66; 568 participants; [Analysis 1.4](#)). Heterogeneity was low among the studies ($I^2 = 18\%$). We performed no subgroup analysis due to too few studies. The result was rated as low based on imprecision of RR estimate with confidence intervals covering both benefit and harm and serious risk of bias in one study.

1.5 Skin rash

[McQueen 1983](#) and [Temkin 1990](#) reported skin rash comparing phenytoin with placebo. About 10.3% (30/292) of participants in the phenytoin group experienced skin rash compared with 6.5% (18/276) in the placebo group. The RR of skin rash in the phenytoin group compared with placebo was 1.65 (99% CI 0.54 to 5.04; 568 participants; [Analysis 1.5](#)). Heterogeneity was low among the studies ($I^2 = 17\%$). We performed no subgroup analysis due to too few studies. The result was rated as low based on imprecision of RR estimate with confidence intervals covering both benefit and harm and serious risk of bias in one study.

1.6 Sensitivity analysis

Occurrence of early seizure: age of population

Four of the five trials that reported on early seizures had a mean or median age that was greater than 18 years ([Glotzner 1983](#); [Young 1983](#); [Temkin 1990](#); [Pechadre 1991](#)). [Young 2004](#) consisted solely of children. We ran the analysis excluding [Young 2004](#). About 4.9% (22/453) of participants treated with an AED experienced an early seizure compared with 15% (65/432) receiving placebo. The result still favored AED treatments compared with placebo; producing a marginally lower RR compared with the original analysis in Section 1.1 (RR 0.36, 95% CI 0.21 to 0.60, $I^2 = 12\%$; [Analysis 1.6](#)) (compare with [Analysis 1.1](#)).

1.7 Sensitivity analysis

Occurrence of early seizure: study quality

Three of the five trials that examined early seizures had high risk of bias in one or more category ([Glotzner 1983](#); [Young 1983](#); [Pechadre 1991](#)). We reran the analysis excluding [Glotzner 1983](#); [Young 1983](#); and [Pechadre 1991](#). The pooled results of the two remaining studies no longer showed a benefit of AED treatment compared with placebo (RR 0.48, 95% CI 0.11 to 2.18, 506 participants; [Analysis 1.7](#)) ([Temkin 1990](#); [Young 2004](#)). Heterogeneity ($I^2 = 68\%$) increased compared with the original analysis (see [Analysis 1.1](#)). Differences

in participant populations likely contributed to the increase in heterogeneity; participants in the [Temkin 1990](#) trial were adults, whereas [Young 2004](#) studied exclusively children.

1.8 Subgroup analysis

Occurrence of late seizure: type of antiepileptic drug

Four of the six trials compared a traditional AED treatment, phenytoin, with placebo for late seizures ([McQueen 1983](#); [Young 1983](#); [Temkin 1990](#); [Pechadre 1991](#)). The two remaining studies treated participants with other AEDs; carbamazepine compared with placebo ([Glotzner 1983](#)), and phenobarbital compared with usual care ([Manaka 1992](#)). In subgroup analysis, 15% (59/393) of participants treated with phenytoin experienced a late seizure compared with 17.5% (63/359) receiving placebo (RR 0.83, 95% CI 0.40 to 1.70; 752 participants; [Analysis 1.8](#)). About 17.6% (22/125) of participants receiving carbamazepine or phenobarbital experienced a late seizure compared with 18.4% (28/152) in the placebo or usual care group (RR 0.96, 95% CI 0.46 to 1.99, 277 participants; [Analysis 1.8](#)). There was no statistically significant subgroup difference between the types of antiepileptic drug ($P=0.78$, $I^2 = 0.0\%$). The subgroup RRs did not differ substantially from the primary analysis results (see [Analysis 1.2](#)).

1.9 Subgroup analysis

Occurrence of late seizure: treatment duration

Five of the six trials that examined the occurrence of late seizures had a treatment duration ranging from 12 to 24 months ([Glotzner 1983](#); [McQueen 1983](#); [Young 1983](#); [Temkin 1990](#); [Manaka 1992](#)). One trial had a treatment duration less than one year ([Pechadre 1991](#)). In subgroup analysis, for treatment duration of 12 to 24 months, 16.3% (79/484) of participants in the AED group experienced late seizures compared with 15.1% (69/459) of participants in the control groups. In the [Pechadre 1991](#) trial, 5.88% (2/34) of participants in the AED treatment group experienced late seizures compared with 42.3% (22/52) in the control group. Although there was no statistically significant subgroup difference between different treatment durations ($P=0.87$, $I^2 = 0.004\%$) the results show greater risk in the AED treatment group for studies with longer treatment duration (12 to 24 months) (RR 1.08, 95% CI 0.81 to 1.46, 943 participants; [Analysis 1.9](#)) while the one study with treatment duration of less than one year showed reduced risk (RR 0.14, 95% CI 0.03 to 0.55, 86 participants; [Analysis 1.9](#)) ([Pechadre 1991](#)).

1.10 Sensitivity analysis

Occurrence of late seizure: age of population

Five of the six trials that examined occurrence of late seizures included both adults and children ([Glotzner 1983](#); [McQueen 1983](#); [Young 1983](#); [Pechadre 1991](#); [Manaka 1992](#)). Removing [Temkin 1990](#), the only study that excluded children, from the analysis did not alter the results substantially. The pooled effect remained statistically non-significant as per the original results (RR 0.81, 95% CI 0.44 to 1.48, 706 participants; [Analysis 1.10](#)) as per the original results (see [Analysis 1.2](#)).

1.11 Sensitivity analysis

Occurrence of late seizure: comparison group

Five trials of the six trials that examined the occurrence of late seizures compared an AED with placebo ([Glotzner 1983](#); [McQueen 1983](#); [Young 1983](#); [Temkin 1990](#); [Pechadre 1991](#)). [Manaka 1992](#)

compared an AED treatment with usual care. The pooled RR, excluding [Manaka 1992](#), remained not statistically significant (RR 0.83, 95% CI 0.48 to 1.41, 903 participants; [Analysis 1.11](#)) (see [Analysis 1.2](#)).

1.12 Sensitivity analysis

Occurrence of late seizure: study quality

Five of the six trials that examined the occurrence of late seizures had a high risk of bias in one or more bias categories ([Glotzner 1983](#); [McQueen 1983](#); [Young 1983](#); [Pechadre 1991](#); [Manaka 1992](#)). [Temkin 1990](#) was the only trial that did not have a high risk of bias in any category. The [Temkin 1990](#) trial favored the placebo group (RR 1.25, 95% CI 0.79 to 1.96, 323 participants; [Analysis 1.18](#)), which differs from the original analysis, which favored the AED treatment (see [Analysis 1.2](#)). However, neither comparison was statistically significant.

1.13 Subgroup analysis

All-cause mortality: age of population

Two studies examined all-cause mortality in children only (ages under 17 years) ([Young 1983](#); [Young 2004](#)). The pooled proportion of children that died in the AED treatment group was 8.5% (8/71) and 22.2% (16/72) died in the placebo group (RR 0.54, 95% CI 0.25 to 1.19, 143 participants; [Analysis 1.13](#)). [Temkin 1990](#) was the only study that exclusively enrolled participants over 17 years of age. About 23.5% (49/208) of adults treated with AED died compared with 20.1% (41/196) of adults receiving placebo. The pooled RR was 1.13 (95% CI 0.78 to 1.62, 404 participants; [Analysis 1.13](#)). The remaining two studies examined all-cause mortality in a predominantly adult population; although children were included ([Glotzner 1983](#); [McQueen 1983](#)). The pooled proportion that died in the AED treatment group was 20.1% (32/159) and 14.1% (22/156) died in the placebo group (RR 1.43, 95% CI 0.90 to 2.27, 315 participants; [Analysis 1.13](#)). The studies including exclusively or predominantly adults showed an increased risk of mortality in the AED group compared with placebo ([Glotzner 1983](#); [McQueen 1983](#); [Temkin 1990](#)), while the studies including only children showed a decreased risk with treatment. The test for subgroup differences showed moderate heterogeneity ($P=0.11$, $I^2=53.9\%$).

1.14 Subgroup analysis

All-cause mortality: treatment duration

Two of the five trials examining all-cause mortality had a short-term treatment duration of less than one week ([Young 1983](#); [Young 2004](#)). 9.9% (18/182) of participants treated with an AED for one week or less died compared with 15.2% (25/164) of participants in the control groups. The pooled RR for these short-term treatments was non-significant and favored AED treatment (RR 0.69, 95% CI 0.39 to 1.24, 346 participants; [Analysis 1.14](#)). In comparison, the three trials that used a treatment duration of a 12 months or longer had a non-significant pooled RR that favored the control group; 22.1% (81/367) of participants in the AED group died compared with 17.9% (63/352) of participants in the control groups (RR 1.24, (95% CI 0.93 to 1.65, 719 participants; [Analysis 1.14](#)) ([Glotzner 1983](#); [McQueen 1983](#); [Temkin 1990](#)). The test for subgroup differences between studies of different treatment duration was statistically significant and suggested moderate heterogeneity ($P=0.08$, $I^2=67.4\%$). Duration of treatment was not further divided into mid-term and long-term duration due to low number of studies.

1.15 Sensitivity analysis

All-cause mortality: type of antiepileptic drug

In four of the five trials that examined mortality, participants received phenytoin in the AED group ([McQueen 1983](#); [Young 1983](#); [Temkin 1990](#); [Young 2004](#)). [Glotzner 1983](#) compared carbamazepine with placebo. Excluding [Glotzner 1983](#), 15.6% (74/474) of participants treated with phenytoin died compared with 15.9% (70/440) of participants who received placebo (RR 0.97, 95% CI 0.65 to 1.43, 914 participants; [Analysis 1.15](#)). The results remain consistent with the original analysis (see [Analysis 1.3](#)).

1.16 Sensitivity analysis

All-cause mortality: study quality

Three of the five trials that examined mortality had a high risk of bias in one or more bias categories ([Glotzner 1983](#); [McQueen 1983](#); [Young 1983](#)). We reran the analysis excluding these studies. The pooled results for the remaining studies with low/unclear risk of bias showed no statistically significant difference between treatment groups ((RR 1.00, 95% CI 0.72 to 1.41) 506 participants; [Analysis 1.16](#)) ([Temkin 1990](#); [Young 2004](#)). The original results were also statistically non-significant, but favored the placebo group (see [Analysis 1.3](#)).

2. Neuroprotective agent versus placebo

Only one study compared a pharmacologic agent (magnesium sulfate; $MgSO_4$) other than an AED with a placebo ([Temkin 2007](#)).

2.1 Occurrence of early seizure

[Temkin 2007](#) reported on the occurrence of early seizures. About 0.4% (1/250) of participants in the neuroprotective agent group experienced an early seizure compared with 0% (0/249) in the placebo group ([Analysis 2.1](#)). However, as reported in the results section of their paper, 96% of participants received phenytoin for the first week in both treatment groups. This may have resulted in a very low early seizure rate.

2.2 Occurrence of late seizure

[Temkin 2007](#) reported on the occurrence of late seizures. About 6% (15/250) of participants treated with neuroprotective agent experienced late seizures compared with 5.6% (14/249) of participants treated with a placebo (RR 1.07, 95% CI 0.53 to 2.17, 498 participants; [Analysis 2.2](#)). There was no evidence of effect of neuroprotective agents compared with placebo on late seizures.

2.3 All-cause mortality

Only [Temkin 2007](#) reported mortality. About 21% (52/250) of participants died in the neuroprotective agent group compared with 14% (35/240) of participants in the control group (RR 1.20, 95% CI 0.80 to 1.81, 466 participants; [Analysis 2.3](#)).

3. Antiepileptic drugs versus other antiepileptic drugs

Two trials compared phenytoin with another AED ([Temkin 1999](#); [Szafarski 2010](#)). [Szafarski 2010](#) compared phenytoin with levetiracetam, a newly licensed AED while [Temkin 1999](#) compared phenytoin with valproate. Treatment duration was one week in the [Szafarski 2010](#) trial compared with up to six months in the valproate arm of the [Temkin 1999](#) study. The age ranges were similar in both studies and neither study showed high bias in

any category. We performed no subgroup analysis due to too few studies and low evidence of heterogeneity between the two studies.

3.1 Occurrence of early seizure

[Szaflarski 2010](#) and [Temkin 1999](#) reported on the occurrence of early seizures and compared phenytoin with another AED. About 3.3% (5/150) of participants treated with phenytoin had an early seizure compared with 5.7% (16/281) of participants treated with another AED. The pooled results of [Szaflarski 2010](#) and [Temkin 1999](#) showed no statistically significant effect of phenytoin compared with another AED (RR 0.66, 95% CI 0.20 to 2.12, 558 participants; [Analysis 3.1](#)). Heterogeneity between the two studies was low ($I^2=29\%$).

3.2 Occurrence of late seizure

[Szaflarski 2010](#) and [Temkin 1999](#) reported on the occurrence of late seizures and compared phenytoin with another AED drug. About 12.4% (17/137) of participants treated with phenytoin experienced late seizures compared with 16.6% (40/241) of participants treated with another AED. The pooled RR of experiencing late seizures on phenytoin compared with another AED was not statistically significant (RR 0.77, 95% CI 0.46 to 1.30, 378 participants; [Analysis 3.2](#)). Heterogeneity between the two studies was low ($I^2=0\%$).

3.3 All-cause mortality

[Szaflarski 2010](#) and [Temkin 1999](#) reported all-cause mortality. About 8.7% (13/150) of participants in the phenytoin group died compared with 16.4% (46/281) of participants in the other AED group. The pooled RR for mortality in the phenytoin group compared with the other AED group was 0.53 (95% CI 0.30 to 0.94; [Analysis 3.3](#)). Heterogeneity between the two studies was low ($I^2=0\%$). We performed no subgroup analysis due to too few studies and low evidence of heterogeneity.

DISCUSSION

Summary of main results

The review included 10 RCTs described in 12 reports, involving 2326 participants. Interventions were reported in three categories; traditional AED versus placebo or usual care, phenytoin versus other AED treatment, and alternative neuroprotective agent versus placebo or usual care.

Five studies with 987 participants studied early seizure in participants treated with a traditional AED compared with placebo or usual care. There was low quality evidence that treatment with a traditional AED (phenytoin or carbamazepine) decreased the risk of early seizure compared with placebo or usual care (RR 0.42, 95% CI 0.23 to 0.73, P value = 0.003).

The risk of late seizure occurrence was reduced by AED treatment compared with placebo or usual care, although the benefit was not statistically significant (RR 0.91, 95% CI 0.57 to 1.46, 1029 participants). The risk of late seizure favored placebo in the only trial that did not have a high risk of bias in any category (RR 1.25, 95% 0.79 to 1.96, 323 participants), although evidence of effect remained non-significant ([Temkin 1990](#)). Caution should be taking when considering this sensitivity analysis as it was based on only one study.

There was no significant difference in mortality between participants in the AED drug and participants in the placebo or usual care group (RR 1.08, 95% CI 0.79 to 1.46, P value = 0.64) although the results were based on very low quality of evidence due to imprecision and inconsistency in results.

The review included only one study that examined other potentially neuroprotective agents compared with placebo or usual care ([Temkin 2007](#)). There was no evidence of treatment effect on late seizures (RR 1.07, 95% CI 0.53 to 2.17) or all-cause mortality (RR 1.20, 95% CI 0.80 to 1.81) for this comparison. There were no events in the placebo arm for the outcome of early seizure and a rate of 0.4% (1/250) early seizures in the treatment group. However, almost all participants (96%) in this study also received phenytoin for the first week following injury. No doses or details on phenytoin treatment levels were provided in the paper.

There was evidence of treatment benefit of phenytoin in comparison to another AED (levetiracetam or valproate). Phenytoin significantly reduced the risk of mortality compared with another AED (RR 0.53, 95% CI 0.30 to 0.94). Caution must be taken as this result was based on only two studies. No treatment benefit of phenytoin was observed compared with another AED for early seizure (RR 0.66, 95% CI 0.20 to 2.12) or late seizure (RR 0.77, 95% CI 0.46 to 1.3).

Only two of the included trials reported any serious treatment-related adverse event. Both trials compared a traditional AED with placebo. There was no evidence of increased risk of adverse effects for the AED group (RR 1.63, 95% CI 0.73 to 3.66). Similarly there was no evidence of increased risk of skin rash (RR 1.65, 99% CI 0.54 to 5.04).

Overall completeness and applicability of evidence

All participants included in the review had a diagnosis of moderate-to-severe TBI. The methods of measurement of severity of TBI varied between studies. The majority of participants were admitted to trauma centers or emergency departments. Participants were randomized and received treatment within 24 hours of admission; however, one study reported that the majority of participants were treated within 14 days post-injury. Three studies allowed the inclusion of participants with an immediate post-injury seizure, while other studies listed this as an exclusion criteria. One study included participants if they had a pre-injury seizure; however, these participants were excluded from outcomes of early and late seizure outcomes. Reporting of outcomes was not consistent across the studies with only two studies reporting any serious adverse event and skin rashes. Two studies also did not document mortality and the majority of studies did not consider time to first seizure or time to second seizure from first seizure. Maintaining therapeutic levels of AED was a challenge in many of the trials with reports of only 40% to 80% of participants maintaining therapeutic levels at follow-up visits. Several studies did not follow the participants beyond the treatment duration, thereby limiting the ability to determine if the treatment effect is sustained once medication is stopped.

Quality of the evidence

Overall quality of the evidence was varied. All included trials were RCTs yet the majority did not adequately describe the randomization and allocation processes clearly. The majority

adequately blinded participants and personnel, but blinding of outcome assessment was considered either unclear or high in five of the 10 trials. Risk of bias of selective reporting was also unclear or high in six trials. Potential sources of bias in this review were: the inability to assess if treatment effects differed between children and adults adequately as children were included in many of the trials and not analyzed separately; and differing treatment protocols regarding timing and duration of treatment, AED dose, maintaining therapeutic levels of AEDs, differences in severity of trauma and different methods of evaluating seizure occurrence. Due to the high proportion of studies in this review that we categorized as unclear and high risk of bias, the findings in this review should be interpreted with caution. The evidence was graded as low to very low for all outcome comparisons based on the high risk of bias previously discussed as well as uncertainty in the estimates with many confidence intervals showing both harm and benefit.

Potential biases in the review process

The Cochrane Epilepsy Review Group conducted a comprehensive search of all published data as well as handsearching the bibliography of selected studies and reviews. We reviewed the full-text reports and two review authors (KT and HA) extracted data and resolved disagreements by discussion to minimize bias. We were unable to obtain further information from some of the trials because they were published many years ago or the authors could not be contacted. We are unable to comment on the potential for publication bias in the review due to the insufficient number of studies to analyze publication bias in funnel plots.

Agreements and disagreements with other studies or reviews

This review differed from the original review by Schierhout 2001 in that we included a study looking at other potentially neuroprotective agents and studies with dual treatment groups. The comparison of traditional AEDs with placebo now includes a study carried out exclusively in children (Young 2004), which was not in the previous review. The results were consistent in both reviews, treatment with traditional AED reduced the risk of early seizure compared with placebo or usual care. When those studies with high bias in at least one category were removed, the evidence of treatment effect was no longer significant. However,

heterogeneity among this subset of studies increased, potentially due to differences in treatment duration and median age of participants.

There was no evidence of treatment effect on late seizure occurrence or mortality. This result was consistent with the results for late seizure occurrence and mortality published in the previous review (Schierhout 2001).

AUTHORS' CONCLUSIONS

Implications for practice

This review found low quality of evidence that early treatment with an antiepileptic drug (AED) compared with a placebo or usual care reduced the risk of early post-traumatic seizures. There was no evidence to support a reduction in the risk of late seizures or mortality. However, these results must be interpreted with caution due to potential bias and high level of heterogeneity among studies and were graded as very low quality. The risk of serious or other adverse events was not greater among treatment versus placebo groups, but this may be due to limited number of trials included in the comparison and small sample size. There was insufficient evidence to make any conclusions regarding the effectiveness and safety of other neuroprotective agents compared with placebo or phenytoin, a traditional AED, compared with another AED.

Implications for research

There have been very few studies in the area, with wide variability in the age of the target population, definition of early seizures, assessment of the extent of brain injury, timing of the intervention, AED dosage and duration of treatment. Further high-quality randomized controlled trials are warranted, particularly for the newly licensed products. Only one published study looking at alternative neuroprotective agents was eligible for inclusion in the review; therefore, further investigation is needed.

ACKNOWLEDGEMENTS

The review authors would like to thank Tracey Daley, Research Assistant for her valued assistance in writing the protocol. We would also like to thank the Nova Scotia Health Research Foundation (NSHRF) for their funding support through the Systematic Review Grant.

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]
Glotzner 1983

Methods	RCT; single center <i>Enrolled:</i> 1978-1979 <i>Duration of treatment:</i> long-term; 18-24 months <i>Follow-up:</i> 18-24 months <i>Setting:</i> Neurosurgery Department of University of Wurzburg <i>Type of agent:</i> traditional AED
Participants	151 participants > 15 years of age, 88.5% male, were admitted due to moderate and severe TBI. Severity determined by GCS and presence of retrospective amnesia Carbamazepine: 75 participants Placebo: 76 participants Pre-existing epilepsy was excluded
Interventions	Carbamazepine: participants were treated according to serum levels 300-600 µg. First dose given immediately after accident (no dosage given), other details not specified Placebo: details not provided First dose given before FPS NOTE: 61% of all 139 participants received additional phenobarbital for brain edema (administered in first week). Mean cumulative dosage: 2780 µg in placebo group vs. 1500 µg in intervention group. 59% of all 139 participants received diazepam: 248 µg in placebo group vs. 150 µg in carbamazepine group: acute phase only
Outcomes	<ul style="list-style-type: none"> • Early seizures • Late seizures • Mortality

Glotzner 1983 (Continued)

Seizure identification: EEG and clinical findings

Notes
Imbalance at baseline: carbamazepine group had more permanent vegetative states 26% vs. 13% placebo
Unable to confirm the data with respect to late seizures; therefore, not included in analysis.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Random sequence predictable - based on birthdays. carbamazepine = even birthdays, placebo = odd birthdays
Allocation concealment (selection bias)	Unclear risk	Allocation concealment not described
Incomplete outcome data (attrition bias) All outcomes	Low risk	Loss to follow-up: 6 from carbamazepine group, 5 from placebo group (poor description of reasons)
Selective reporting (reporting bias)	High risk	Very detailed description of severity of injury (over 50 baseline descriptive tables) but no adverse events reported
Other bias	High risk	Majority of participants received phenobarbital or diazepam, or both (both active AEDs) in the first week for edema treatment
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Is not stated if participants or physicians were blinded
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Study indicated as "blinded"; blinding of assessment not specifically reported

Manaka 1992

Methods
RCT; multicenter; parallel group study
Enrolled: 1983-1985
Duration of treatment: long-term; 2 years
Follow-up: 5 years
Setting: Japan
Type of agent: traditional AED

Participants
244 participants ages 7-88 years admitted due to TBI
Analyzed:
Group I with severe TBI (mean age 38 ± 19.9 years):

- Group IA: 50 participants received phenobarbital
- Group IB: 76 participants received usual care

Manaka 1992 (Continued)

Group II with mild TBI: 65 participants; mean age 29.3 ± 19.6 years): treatment not described

Proportion male: not reported

Did not specify if pre-existing epilepsy was excluded

Interventions	<p>Group IA: received phenobarbital, 10-25 µg/mL, started 4 weeks after TBI. Full dose for 2 years, tapered in third year</p> <p>Group IB: some participants received nothing, some participants received anticonvulsants</p> <p>Group II: intervention not specified</p> <p>First dose given before an FPS: not reported</p>
---------------	--

Outcomes	<ul style="list-style-type: none"> • Late seizures • Cumulative seizure occurrence rate • Risk factors for seizures <p><i>Seizure identification:</i> not specified</p>
----------	--

Notes	<p>Baseline characteristics not reported</p> <p>Drug not administered until approximately 2 months post-injury; some early seizures occurred</p> <p>Control group appeared to include participants who were taking other anticonvulsant drugs</p>
-------	---

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No further details provided; therefore, no confirmation method was carried out appropriately
Allocation concealment (selection bias)	Unclear risk	Allocation concealment process not described: used envelope method; no further details provided.
Incomplete outcome data (attrition bias) All outcomes	High risk	<p>Loss to follow-up at 5 years was 25%. 52/244 excluded due to drop-out or "against" protocol. No mention of which groups these participants were in, their characteristics, if they were randomized or if they received treatment prior to drop-out. Intention-to-treat not performed</p> <p>No Table 1 to clearly describe participant characteristics</p> <p>No clear description of drug protocol or control protocol for Group IB and Group II</p>
Selective reporting (reporting bias)	High risk	Did not report on adverse events or mortality. Baseline characteristics were not reported; therefore, cannot assess balance of baseline characteristics
Other bias	High risk	Co-intervention in control group. Group IB had some participants who received anticonvulsant medication and other participants who did not receive anticonvulsant medication. Not sure what proportion received medication or what drugs were
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	No mention of blinding participants or personnel

Manaka 1992 (Continued)

Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	No mention of blinding outcome assessors
---	--------------	--

McQueen 1983

Methods

RCT; double-blind, multicenter (2 sites), parallel-group study

Enrolled: Newcastle, UK: November 1977 to October 1979; Edinburgh, UK: 1 January 1977 to October 1979

Duration of treatment: mid-term; 12 months

Follow-up: 2 years

Setting: Neurological Surgery Departments

Type of agent: traditional AED

Participants

164 participants ages 5-65 years admitted due to TBI

Phenytoin: 84 participants; 35% were 5-15 year olds; 79% male

Placebo: 80 participants; 18% were 5-15 year olds; 80% male

85% of participants had injuries associated with high risk of post-traumatic epilepsy

Pre-existing epilepsy was excluded

Interventions

Phenytoin: child (5-15 years 5 mg/kg; adults 300 mg)

Placebo:

Therapeutic dose: during follow-up, adjusted to achieve plasma concentration 40-80 µmol/L

Dose administration: capsule of phenytoin 50 or 100 mg and matching placebo capsules

Timing of dose: single or divided daily dose; not precisely reported but participants received a full dose every 24 hours

First dose given before post-traumatic seizure; early seizure was an exclusion criteria

Outcomes

- Late seizures
- Time to first seizure
- Mortality
- Adverse events

Seizures diagnosed based on clinical findings

Notes

Potentially significant difference in participant characteristics at baseline

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Treatment was administered by the hospital pharmacist using a prepared list of random treatment allocation - but report did not indicate how the list was made.

McQueen 1983 (Continued)

Allocation concealment (selection bias)	Low risk	Treatment was administered by the hospital pharmacist using a prepared list of random treatment allocation - but report did indicate how the list was made.
Incomplete outcome data (attrition bias) All outcomes	Low risk	Loss to follow-up over 2 years was 1%. Authors explained causes of participants lost to follow-up. These participants were counted in the treatment group to which they were originally assigned
Selective reporting (reporting bias)	Low risk	There was no evidence of selective reporting. Prespecified outcomes reported
Other bias	High risk	<p>Potentially significant difference at baseline. In phenytoin group, more 5-15 year olds than in placebo group. In phenytoin group, more participants admitted in 8-10 days post injury. In placebo group, more participants admitted > 30 days post-injury</p> <p>Low compliance in treatment group. 80% were dispensed capsules for up to 6 months, 68% for up to 9 months, 49% for up to 12 months</p> <p>When tested, the level of phenytoin in the plasma of the phenytoin group often below the therapeutic level with only 48% of participants achieving plasma concentrations of > 40 µmol/L on at least 1 occasion, 36% had plasma concentrations of 20-39 µmol/L, 12% in range 10-19 µmol/L</p>
Blinding of participants and personnel (performance bias) All outcomes	Low risk	The trial was conducted 'double-blind' with prescribed treatment known only to the hospital pharmacy and the trial co-ordinators, who had no responsibility for participant care or follow-up
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Assessors involved in the prescribed treatment were not involved in follow-up

Pechadre 1991

Methods	<p>RCT</p> <p><i>Enrolment:</i> January 1982 to March 1985</p> <p><i>Duration of treatment:</i> short-term and mid-term; 3 months and 1 year</p> <p><i>Follow-up:</i> 2 years</p> <p><i>Setting:</i> France</p> <p><i>Type of agent:</i> traditional AED</p>
Participants	<p>86 participants aged 5-60 years, 80% males admitted due to severe TBI</p> <p>Phenytoin: 34 participants); mean age 26 years; 74% male</p> <p>Placebo: 52 participants; mean age 30.3 years; 85% male</p> <p>Pre-existing epilepsy was excluded</p> <p>Severity determined by EEG and repeat CT scans</p>
Interventions	Phenytoin: 10 mg/kg by slow intravenous pump 40 mg/minute

Pechadre 1991 (Continued)

Placebo:

Therapeutic dose: determined by serum results at 48 hours and 7 days - adjusted therapeutic doses using formula by [Young 1979](#).

Dose administration: capsule of phenytoin 50 or 100 mg and matching placebo capsules

Timing of doses: 4 divided doses on first day; on second day, oral phenytoin (gastric tube in some participants), mean dose 8 mg/kg in 2 divided doses. Treated within 24 hours of accident and upon arrival in ICU

Not reported if first dose was given before post-traumatic seizure

Outcomes	<ul style="list-style-type: none"> • Early seizures • Late seizures • Types of seizures that occurred <p>Seizures diagnosed based on clinical findings and EEG</p>
----------	---

Notes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Randomized by day of arrival even or odd day (predictable sequence)
Allocation concealment (selection bias)	Unclear risk	Did not describe allocation concealment. Predictable sequence of randomization
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	5 participants excluded from analysis due to death in first 5 days - group allocation not indicated. Loss to follow-up other than mortality was not discussed
Selective reporting (reporting bias)	High risk	Indicated that some participants received phenytoin for > 3 months but did not describe outcomes by length of treatment. Adverse events and mortality not reported for included participants
Other bias	Unclear risk	No clear description of the control group
Blinding of participants and personnel (performance bias) All outcomes	High risk	Did not mention blinding strategies - but given nature of randomization, it would be easy to determine which participants were in control/treatment groups
Blinding of outcome assessment (detection bias) All outcomes	High risk	Given the allocation by date of enrolment - it is unlikely that treatment was blinded as the assessors could easily determine which participants were in which group by date of admission

Szafarski 2010

Methods	RCT; double-blind, single-center, parallel group study <i>Enrolled:</i> not reported <i>Duration of treatment:</i> short-term; 7 days
---------	---

Szaflarski 2010 (Continued)

Duration of follow-up: outcomes assessed at 3 and 6 months

Setting: USA; neuroscience ICU

Type of agent: traditional AED and newly licensed AEDs

Participants	<p>52 participants with severe TBI or subarachnoid hemorrhage ages 17-80 years. Randomization up to 24 hours post admission, at a 2 : 1 ratio levetiracetam : phenytoin</p> <p>Levetiracetam: 34 participants; 30 with TBI; ages 17-75 years, median 44 years; 77% male</p> <p>Phenytoin: 18 participants; 16 with TBI; ages 18-80 years, median 25 years; 72% male</p> <p><i>Inclusion:</i> TBI or subarachnoid hemorrhage, GCS (3-8 inclusive) or GCS of ≤ 5 and abnormal CT scan showing intracranial pathology, hemodynamically stable, at least 1 reactive pupil, ages ≥ 17 years and informed consent</p> <p><i>Exclusion:</i> spinal cord injury, previous brain injury, known hypersensitivity to anticonvulsant, hemodynamically unstable, anoxic events</p> <p>Report did not indicate exclusion of pre-existing seizures prior to study inclusion but author confirmed exclusion by email</p>
--------------	--

Interventions	<p>Levetiracetam: loading dose 20 mg rounded to nearest 250 mg over 60 minutes. Maintenance dose of 1000 mg, IV every 12 hours over 15 minutes. Therapeutic dose: up to 1500 mg (3000 mg/day). Duration of treatment: 1-7 days</p> <p>Phenytoin: loading dose of 20 mg/kg IV, maximum 2000 mg over 60 minutes and then phenytoin maintenance of 5 mg/kg/day rounded to nearest 100 mg, dose every 12 hours. Therapeutic dose: 10-20 $\mu\text{g}/\text{dL}$. Duration of treatment range: 1-7 days</p> <p>Not reported if drug was given before first seizure</p>
---------------	--

Outcomes	<ul style="list-style-type: none"> • Early seizures • Late seizures • Mortality • Neurologic outcomes <p>Seizures identified based on clinical findings. Continuous EEG monitoring for first 72 hours</p>
----------	---

Notes	<p>Baseline characteristics appeared balanced between study groups</p> <p>People with TBI or subarachnoid hemorrhage recruited and it was not possible to obtain data exclusively for the people with TBI, which represented 89% of the participants</p>
-------	--

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No details on method of randomization. Randomized at a 2 : 1 ratio of levetiracetam : phenytoin
Allocation concealment (selection bias)	Low risk	Participants randomized and treatment group assigned by the pharmacy
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	Participants were analyzed as survivors and as per their treatment group assignment. No indication of any loss to follow-up other than death
Selective reporting (reporting bias)	Low risk	All expected and pre-specified outcomes were reported

Szafarski 2010 (Continued)

Other bias	Unclear risk	No report of drug levels to assess efficacy
Blinding of participants and personnel (performance bias) All outcomes	Unclear risk	Physicians "partially" blinded. Were not "told" group assignment, but PHT levels could be reviewed. Physicians were also unblinded if a seizure occurred to optimize treatment
Blinding of outcome assessment (detection bias) All outcomes	Low risk	EEG monitoring occurred for 72 hours. Electrophysiologist was blinded to the group assignment and diagnosis The clinical research co-ordinator remained blinded to participant medication and conducted all assessments

Temkin 1990

Methods	<p>RCT; double-blind, single center, parallel group study</p> <p><i>Enrolled:</i> November 1983 to December 1987</p> <p><i>Duration of treatment:</i> mid-term; 12 months</p> <p><i>Follow-up:</i> 2 years</p> <p><i>Setting:</i> USA, Level 1 trauma center</p> <p><i>Type of Agent:</i> traditional AED</p>
Participants	<p>404 participants with severe TBI, mean age 34 ± 18 years</p> <p>Phenytoin: 208 participants; mean age 34 ± 18 years; 78% male</p> <p>Placebo: 196 participants; mean age 34 ± 17 years; 75% male</p> <p>Eligibility - meet at least 1 of following criteria: cortical contusion visible on CT scan; a subdural, epidural or intracerebral hematoma; a depressed skull fracture; penetrating head wound; seizure within 24 hours of injury or a GCS ≤ 10 on admission. If any criteria met - estimated 20% chance of seizure</p> <p>Excluded participants with previous documented unprovoked seizures</p>
Interventions	<p>Phenytoin (Dilantin): initial dose 20 mg/kg IV within 24 hours of injury</p> <p>Therapeutic dose: total 40-80 µmol/L, 10-20 mg/L</p> <p>Dose administration: daily dose varied based on individual serum level; range 200-1200 mg to maintain serum levels</p> <p>Placebo: given daily</p> <p>First dose not given before an FPS</p>
Outcomes	<ul style="list-style-type: none"> • Early seizures • Late seizures • Mortality • Adverse events <p><i>Seizure identification</i> based on clinical findings. Clinicians who were blinded to treatment diagnosed seizures primarily on basis of clinical manifestations especially involuntary movements; alterations in consciousness; or abnormal motor, sensory or psychosensory phenomena. Participants and caregivers were trained to recognize subtle manifestations of seizures</p>

Temkin 1990 (Continued)

Notes Baseline characteristics were comparable between groups
 Additional data regarding the group without prior seizure history was received from Dr. Temkin

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomization process not reported
Allocation concealment (selection bias)	Unclear risk	Concealment of allocation process not reported
Incomplete outcome data (attrition bias) All outcomes	Low risk	Randomized participants were analyzed in the groups they were allocated to. Withdrawal from treatment well reported. 24% of participants lost to follow-up; 23% in phenytoin group and 26% in placebo group over 24 months
Selective reporting (reporting bias)	Low risk	Expected outcomes of interest appear to be reported
Other bias	Low risk	Study groups similar baseline characteristics with respect to demographic characteristics, cause of injury, and severity of injury. 70% of participants had therapeutic levels of phenytoin
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Dose modified by unblinded study staff. Similar "mock" adjustments made to placebo group. Treatment code was not broken unless phenytoin appeared to be responsible for reaction and the participant's condition warranted such action
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Clinicians who were blinded to treatment diagnosed seizures primarily on basis of clinical manifestations

Temkin 1999

Methods	RCT; double-blind, single-center, parallel-group study <i>Enrolled:</i> November February 1991 to December 1995 <i>Duration of treatment:</i> varied 2 groups short-term; 1 week and 1 month treatments; 1 group mid-term - 6 month treatment <i>Follow-up:</i> 2 years <i>Setting:</i> USA, level 1 trauma center <i>Type of agent:</i> traditional AED
Participants	379 participants with TBI randomized to: <ul style="list-style-type: none"> • Phenytoin for 1 week (132 participants), mean age 36 ± 16 years; 84% male; mean GCS 11.7 ± 3.8 • Valproate for 1 month (120 participants), mean age 40 ± 19 years; 84% male; mean GCS 11.6 ± 3.6 • Valproate for 6 months (127 participants), mean age 36 ± 16 years; 77% male; mean GCS 11.1 ± 3.8 Qualifying injury had 1 of the following characteristics: immediate posttraumatic seizures. Depressed skull fracture, penetrating brain injury, or CT evidence of cortical contusion or subdural, epidural, intracerebral hematoma

Temkin 1999 (Continued)

Excluded people with previous documented unprovoked seizures

Interventions	<p>Phenytoin (1 week): loading dose IV 20 mg/kg - administered within 24 hours. Maintenance dose 5 mg/kg/day in two divided doses. Therapeutic dose: 40-80 µmol/L (10-20 µg/mL)</p> <p>Valproate (1 and 6 months): loading dose IV 20 mg/kg. Maintenance dose 15 mg/kg/day in 4 divided doses. Therapeutic dose - 277-693 µmol/L (40-100 µg/mL)</p> <p>First dose not given before an FPS</p>
Outcomes	<ul style="list-style-type: none"> • Early seizures • Late seizures • Mortality • Adverse events • Compliance <p><i>Seizure identification:</i> based on clinical findings. Early seizures were witnessed by medical personnel. Late seizures recognized by participants and caregivers who reported them to study neurologist. A blinded study neurologist reviewed all suspected seizures; if in doubt, the event was not counted as a seizure</p>
Notes	<p>For early seizures the valproate group was considered as 1 group regardless of length of time to be treated</p> <p>All participants were included in the analysis of late seizures regardless of whether they had experienced early seizures</p> <p>Baseline characteristics were comparable between groups</p>

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated blocked randomization list, generated by statistician and kept in locked part of pharmacy
Allocation concealment (selection bias)	Low risk	Allocation by pharmacist
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	<p>87% followed for full 2 years. But not all participants followed through with assigned treatment. Of randomized cases: 75% of 1 month and 70% of 6 month valproate group followed up for 2 years. 79% of phenytoin group followed for 2 years</p> <p>Because most participants were unconscious or had cognitive impairments during the first week, early seizures without a prominent motor component were likely to be overlooked</p> <p>113 participants initially randomized were subsequently found to be ineligible after randomization for issues such as prior history of epilepsy. These participants were only observed for 28 days for incidence of adverse effects and for mortality</p>
Selective reporting (reporting bias)	Unclear risk	Although most expected and pre-specified outcomes appeared to be reported, denominators of counts not reported clearly
Other bias	Low risk	Valproate concentrations were at or above the target valproate range in 97% of participants in first week; 90% in first month; 85% in fifth month

Temkin 1999 (Continued)

Phenytoin concentrations were at or above the target phenytoin range in 91% of participants in the first week

Compliance: 16% stopped taking blinded medication before 1 month because of participant preference or mild adverse effects. 21% stopped before 6 months compliance reported for each group

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Identical-appearing IV solutions and call-backs to check placebo "drug levels" to maintain blind conditions
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Neurologist blinded to the assignment made the final determination on seizure diagnosis for the study

Temkin 2007

Methods	<p>RCT; double-blind, single-center, parallel group study</p> <p><i>Enrolled:</i> August 1998 to October 2004</p> <p><i>Duration of treatment:</i> short-term; 5 days</p> <p><i>Follow-up:</i> 6 months</p> <p><i>Setting:</i> USA, level 1 trauma center</p> <p><i>Type of agent:</i> "other"</p>
Participants	<p>499 participants older than 14 years were admitted due to moderate or severe TBI</p> <p>Treatment 1 (high dose magnesium sulfate; MgSO₄):</p> <ul style="list-style-type: none"> Placebo: 59 participants; mean age 36.2 ± 18.3, 66% ≤ 40. Trauma severity: 51% moderate, 49% severe; mean GCS: 7.0 ± 3.0, 78% male Treatment: 59 participants; 34.7 ± 14.9, 63% ≤ 40. Trauma severity: 59% moderate, 41% severe; mean GCS: 7.3 ± 2.9, 76% male <p>Treatment 2 (low-dose magnesium sulfate; MgSO₄):</p> <ul style="list-style-type: none"> Placebo: 190 participants; 33.9 ± 17.6, 72% ≤ 40. Trauma severity: 59% moderate, 41% severe; mean GCS: 7.1 ± 2.8, 76% male Treatment: 191 participants; 34.1 ± 17.1, 69% ≤ 40. Trauma severity: 64% moderate, 36% severe; mean GCS: 7.1 ± 2.8, 76% male <p>Moderate to severe was defined as: the need for intracranial surgery within 8 hours of injury; a post-resuscitation GCS score of 3-12; or intubated, a GCS motor score of 1-5 without pharmacologic paralysis</p> <p>Pre-injury seizures were not excluded from the study, but participants with pre-injury seizures were excluded from seizure outcome analysis</p>
Interventions	<p>Treatment 1 (high dose): magnesium sulfate (MgSO₄) high dose 1.2-2.5 mmol/L. Initial IV load of 0.425 mmol/kg over 15 minutes followed by continuous infusion (0.10 mmol/kg/hour) to maintain target range for 5 days. Therapeutic dose 1.25-2.5 mmol/L</p> <p>Treatment 2 (low dose): magnesium sulfate (MgSO₄) low dose 1.0-1.85 mmol/L. Initial IV load of 0.30 mmol/kg over 15 minutes followed by continuous infusion (0.05 mmol/kg/hour) to maintain target range for 5 days. Therapeutic dose 1.0-1.85 mmol/L</p>

Temkin 2007 (Continued)

In both treatments, agent was administered within 8 hours of injury. Infusion rate adjusted daily by pharmacist

Placebo: saline, magnesium sulfate given below normal levels

Not reported if drug was given before first seizure

96% of participants received phenytoin for the first week as part of clinical care

Outcomes

- Early seizures
- Late seizures
- Mortality
- Adverse effects

Seizure identification not explicitly reported, but, at 1 and 3 months, health status measures were assessed by telephone and as a part of a formal in-person comprehensive examination at 6 months that included neuropsychologic testing (panel). A family member who knew the person prior to injury also participated in assessment at 6-month test

Notes

Participants who died before day 8 were excluded from the late seizure analysis

Author contacted: contacted for participant details within outcome categories to determine if history of seizure was excluded. Response summary: participants with history of seizure were deleted from early and late seizure outcome. Author provided counts for primary and secondary outcomes

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomization was stratified by sex and age. Randomization was blocked (2-4 people) to ensure balance. Computer-generated list kept in a restricted area of the pharmacy
Allocation concealment (selection bias)	Low risk	Pharmacist randomly assigned participant sequentially when order received
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	<p>Primary analysis excluded people with fixed dilated pupils and people who were randomized but died before receiving the drug (7 in magnesium sulfate group, 8 in placebo group). In secondary analysis, all participants were analyzed in the groups they were assigned (ITT analysis)</p> <p>93% were followed for 6 months. 72% had a full neurologic assessment at 6 months</p> <p>Loss to follow-up similar in both the Mg (18) and placebo (19) groups and for similar reasons</p>
Selective reporting (reporting bias)	Unclear risk	Did not report mortality and seizures in a conventional way for these common study outcomes
Other bias	Unclear risk	<p>Co-intervention: phenytoin administered to 96% of participants in the first week</p> <p>Most characteristics were "quite" well balanced at baseline, but the lower magnesium dose had more participants with hematomas and with worse abbreviated-injury-scale-head scores. Noted significant differences in P values between group in age, severity and gender</p> <p>Drug treatment as specified was given in 95% of cases</p> <p>25 participants stopped taking study drug before the 5 days</p>

Temkin 2007 (Continued)

Pre-injury seizures were not excluded, but participants with pre-injury seizures were excluded from seizure outcome analysis

Total mean magnesium concentrations were 2.15 mmol/L (SD 0.35) in high-dose group, 1.45 mmol/L (SD 0.2) in low-dose group and 0.9 mmol/L (SD 0.1) in placebo group

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Participants, doctors and nurses treating participants were all blinded to assignment. Clinicians were not allowed to order any tests of magnesium concentration during the infusion or for 2 days post drug treatment. Masking was broken in 8% of cases - usually when clinician ordered routine laboratory tests. Research nurse became aware of 4% of cases. Participants remained constantly unaware of assignment
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Research nurses and professionals involved in assessment of outcome were all masked to treatment assignment. There was no formal assessment of the success of the masking. Outcome examiners remained consistently unaware of assignment

Young 1983

Methods	RCT; double-blind, single-center; parallel-group study <i>Enrolled:</i> December 1976 to November 1979 <i>Duration of treatment:</i> short-term 7 days and long-term 18 months <i>Follow-up:</i> 1 week to 18 months <i>Setting:</i> USA, neurologic services <i>Type of agent:</i> traditional AED Results of trial reported in 3 reports. Report A: Young 1983. Journal of Neurosurgery 1983;58(2):231-5; all participants; early seizure only. 1-week follow-up. Report B: Journal of Neurosurgery 1983;58(2):236-41; all participants; late seizures only, 18-month follow-up. Report C: Child's Brain 1983;10(3):1985-92, subanalysis of Report B - all participants aged < 17 years
Participants	<p>Report A: 244 participants of all ages with severe TBI</p> <p>Phenytoin: 136 participants; mean age 24.4 ± 1.29 years; 6 (4.4%) ages 0-4 years ; 26 (19.1%) ages 5-15 years; 80.9% male</p> <p>GCS: 14 (10.3%) had GCS 3-4; 56 (41.2%) had GCS of 5-7; 56 (48.5%) had GCS ≥ 8. 7 had pre-randomized seizures (mean age 12 years)</p> <p>Placebo: 108 participants; mean age 25.8 ± 1.47 years; 5 (4.6%) ages 0-4 years; 17 (15.7%) ages 5-15 years; 84.3% male</p> <p>GCS: 17 (15.7%) had GCS 3-4; 46 (42.6%) had GCS 5-7; 45 (41.7%) had GCS ≥ 8. 3 had pre-randomized seizures (mean age 12 years)</p> <p>Report B: 214 participants of all ages, mean age of 25.2 years, with severe TBI. 4.7% aged < 5 years, 17.3% ages 5-16 years, 78.0% > 16 years</p> <p>Phenytoin: 119 participants; mean age 24.4 ± 1.29 years; 6 (4.4%) ages 0-4 years; 26 (19.1%) ages 5-15 years; 80.9% male</p> <p>GCS: 9 (8.6%) had GCS 3-4; 40 (38.1%) had GCS 5-7; 56 (53.3%) had GCS ≥ 8</p> <p>Phenobarbital: 20 participants; received phenytoin initially; mean age 21.6 ± 3.01, 75% male.</p>

Young 1983 (Continued)

GCS: 0 (0%) had GCS 3-4; 11 (55.5%) had GCS 5-7; 9 (45.0%) had GCS of ≥ 8

Placebo: 95 participants; mean age 26.3 ± 2.03 years; 82.4% male

GCS: 8 (10.8%) had GCS 3-4; 33 (44.6%) had GCS 5-7; 33 (44.6%) had GCS ≥ 8

Report C: 46 participants all age of 17 years with severe TBI. Randomized: 27 to treatment, 19 to placebo. 4 died and 1 early seizure excluded from analysis

Follow-up:

Phenytoin: 20 participants; mean age 9.3 ± 0.81 years; 72% male.

GCS: 1 (5.0%) had GCS 3-4; 5 (25.0%) had GCS 5-7; 14 (70.0%) had GCS ≥ 8 . (5 switched to phenobarbital)

Phenobarbital: 5 participants; received phenytoin initially. Mean age 9.0 ± 1.92 years, % male unknown

GCS: 0 (0%) had GCS 3-4; 4 (80.0%) had GCS 5-7; 1 (20.0%) had GCS ≥ 8

Placebo: 16 participants; mean age 9.2 ± 1.15 years; 93.8% male

GCS: 2 (12.5%) had GCS 3-4; 4 (25.0%) had GCS 5-7; 10 (62.5%) had GCS ≥ 8

Included people with penetrating head wound or blunt head injury providing > 10% chance of developing seizures. Participants had: intracranial hematomas; frontal, temporal, or parietal depressed skull fracture; and other blunt head injuries causing unconsciousness for at least 6 hours or major focal neurologic deficits. Some seizures occurred prior to first dose

Interventions

Phenytoin: initial dose 11 mg/kg at 25 mg/minute plus 13 mg/kg intramuscularly

If levels were adequate 8.8 mg/kg administered daily or adjusted as needed. Therapeutic dose: plasma concentrations 10-20 $\mu\text{g/ml}$. Timing of dose: administered with 24 hours of admission

Placebo: identical IV of phenytoin diluent (10% ethanol, propylene glycol 40% and water 50%) or placebo capsule

Outcomes

- Early seizures (within first week, time to first and mean number of seizures)
- Late seizures (after first week and median time to late seizure)
- Mortality
- Type of seizure

Notes

Method of identification of early seizure was not reported. Identification of late seizure by interview, exam, written and telephone follow-ups

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not reported; "randomized" but did not say how
Allocation concealment (selection bias)	Unclear risk	Not reported
Incomplete outcome data (attrition bias) All outcomes	Unclear risk	A number of participants were lost to follow-up or excluded from the analysis. Report A: 1 participant who had a drug reaction was excluded from the results. Report B: 179/214 followed for 18 months. 4 participants had early seizures in placebo group and were eliminated as they were administered phenytoin (3 people) or phenobarbital (1 person). 11 participants lost to follow-up: 3 in drug group, 8 in placebo. 20 participants died in first week: 11 in drug group and 9

Young 1983 (Continued)

		in placebo group. Report C : participants were analyzed in the group they were assigned regardless of outcome
Selective reporting (reporting bias)	High risk	Results indicated that deaths occurred beyond those reported in first 7 days. Median time to death was reported with ranges from 8 to 450 days but number of deaths between week 2 and 18 months not reported. Types of adverse reactions not reported despite 20 participants switched to phenobarbital. Did not include lost to follow-up in time to event analysis
Other bias	Unclear risk	<ul style="list-style-type: none"> • Did not report how seizures were evaluated • Variable levels of blood concentrations and compliance among participants reported. Authors admitted challenges with maintaining compliance with drug protocol over long trial. In week 1, 78% of participants receiving phenytoin had plasma concentrations of at least 10 µg/mL at 1, 3 and 7 days. Week 2 to 18 months: compliance - 50% of participants with known blood concentrations of phenytoin were compliant but the blood levels were only known in 25% of the participants • Inconsistencies in obtaining full follow-up data. "In some cases telephone reports were necessary to obtain full 18 month follow-up"
Blinding of participants and personnel (performance bias) All outcomes	Low risk	State: "only the clinical pharmacist or the clinical nurse on the team was aware of which participant was receiving active drug or the placebo and made dosing adjustments"
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	State: "In all cases the physician evaluators were blinded as to the drug received"; however, unclear if blinding was broken when participants were switched from phenytoin to phenobarbital

Young 2004

Methods	RCT; double-blind, multicenter, parallel-group study <i>Enrolled:</i> December 1992 to November 1997 <i>Duration of treatment:</i> short-term; 5 days <i>Follow-up:</i> 30 days; median time 34.5 days (interquartile range 30-50 days) <i>Setting:</i> USA, urban pediatric trauma centers <i>Type of agent:</i> traditional AED
Participants	103 participants aged < 10 years, range of 3.3-9.4 years, median 6.1 years with moderate and severe TBI. 68% male Phenytoin: 47 participants*; age range 3.7-9.6 years, median 6.4 years; 67% male Placebo: 56 participants; age range 2.6-8.8 years, median 5.9 years; 68% male Severity of TBI determined by: acute blunt head injury, with marked alteration in level of consciousness as defined by GCS (≤ 10 in children aged ≥ 4 years; ≥ 9 in children aged < 4 years, and pulse rate > 60 beats/minute)
Interventions	Phenytoin: initial IV dose 18 mg/kg over 20 minutes, maintenance 2 mg/kg every 8 hours for 48 hours (5 doses). Drug administered within 60 minute of arrival in emergency room Placebo: diluent alone. First dose was administered prior to first traumatic seizure

Young 2004 (Continued)

- Outcomes
- Early seizures
 - Mortality
 - Neurologic outcomes

Seizures were identified with EEG and clinical finding

Notes

Excluded participants who had post-trauma seizures before randomization

* 1 participant in phenytoin group was removed from the study at the request of the family

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Enrolment was intended to be consecutive. Participants stratified into 6 groups according to age and initial GCS. Within each of the 6 stratified groups and study site, participants were randomly allocated to phenytoin or placebo by using randomized permuted blocks to ensure baseline similarity of treatment groups
Allocation concealment (selection bias)	Low risk	A code kept locked in an office off site was available only to the principal investigator linking each vial to the contents of the vial (phenytoin or placebo). Sealed envelopes with the identity of the study medication were kept with the vials and in the participant's medical record. The envelopes were to be opened at the end of the 48-hour observation period, if a participant experienced a seizure or if the attending neurosurgeon wished to withdraw the participant from the study
Incomplete outcome data (attrition bias) All outcomes	Low risk	68% completed entire observation period; 6 seizures, 9 deaths, 1 surgery, 12 discharged home, 5 protocol violations or neurosurgeons request Of 82/102 remaining participants, 62 (76%) returned for 30-day follow-up. Telephone follow-up obtained from 4 others. Total follow-up including deaths = 86/102 (84%). Randomized participants were analyzed in the groups they were allocated to. 10 lost to follow-up from phenytoin group and 6 lost to follow-up from placebo group
Selective reporting (reporting bias)	Low risk	Expected outcomes analyzed and reported
Other bias	Unclear risk	Median serum phenytoin levels: 16.2 mg/L (range 3.3-61) Serum levels in the participants who had post-traumatic seizures was 2.3, 34, 13 mg/L Ideal study therapeutic dose of phenytoin not stated Emergency room administration of benzodiazepines and barbiturates: differences approached significance between the groups (see report, Table 3) Administration of paralytic agents in the pediatric ICU and potential seizures were not monitored by EEG. Unlikely to introduce bias due to blinding, but number of seizures reported may underestimate the true early seizure rate 18% of participants had been receiving anticonvulsant medications at some point since hospital discharge and prior to 30 day follow-up
Blinding of participants and personnel (performance bias)	Low risk	Study medication and identical-appearing placebo were prepared by the pharmacy. A code kept locked in an office off site was available only to the principal

Young 2004 (Continued)

All outcomes		investigator linking each vial to the contents of the vial (phenytoin or placebo). Group assignment concealed until end of 48-hour observation
Blinding of outcome assessment (detection bias) All outcomes	Unclear risk	Group assignment concealed until end of 48-hour observation (low risk) Unclear for secondary outcomes as the groups would have been unblinded for 30-day assessment (unclear risk)

AED: antiepileptic drug; CT: computed tomography; EEG: electroencephalography; FPS: first post-traumatic seizure; GCS: Glasgow Coma Scale; ICU: intensive care unit; ITT: intention to treat; IV: intravenous; RCT: randomized controlled trial; SD: standard deviation; TBI: traumatic brain injury.

Characteristics of excluded studies [ordered by study ID]

Study	Reason for exclusion
Anderson 2000	Not RCT or quasi-randomized trial

Characteristics of ongoing studies *[ordered by study ID]*

NCT01048138

Trial name or title	Use of Biperiden for the Prevention of Post-Traumatic Epilepsy
Methods	Placebo-controlled, randomized, double-blind study
Participants	132
Interventions	Biperiden lactate and placebo
Outcomes	Onset of post-traumatic epilepsy, quality of life; cognitive level
Starting date	2013
Contact information	Luiz Eugenio Mello, Federal University of São Paulo, lemello@unifesp.br
Notes	ClinicalTrials.gov/show/NCT01048138

NCT01673828

Trial name or title	Allopregnanolone for the Treatment of Traumatic Brain Injury
Methods	Double-blind, placebo-controlled, randomized, dose-finding, 2-stage adaptive, clinical trial comparing allopregnanolone to placebo when administered intravenously for 5 days beginning within 8 hours after injury
Participants	136
Interventions	Allopregnanolone and placebo
Outcomes	Extended Glasgow Outcome Scale (GOS-E) Score; mortality; depression; late post-traumatic epilepsy; Neurobehavioral Rating Scale Revised (NRS-R); Test of Adult Reading; Tests of Executive Function; Tests of Learning, Delayed Recall, and Recognition; Test of Working Memory; Tests of Psychomotor and Processing Speed; depression; quality of life; anxiety
Starting date	2013
Contact information	University of California, Davis Medical Center. Nancy Rudisill nancy.rudisill@ucdmc.ucdavis.edu / Steffany Lim steffany.lim@ucdmc.ucdavis.edu
Notes	ClinicalTrials.gov/show/NCT01673828

NCT02027987

Trial name or title	Traumatic neuroprotection and epilepsy prevention of Valproate acid
Methods	160 participants who were in a vegetative or minimally conscious state 4 to 16 weeks after TBI and who were receiving inpatient rehabilitation. Participants were randomly assigned to receive VPA or placebo for 4 weeks and were followed for 2 weeks after the treatment was discontinued. The rate of functional recovery on the Disability Rating Scale (DRS; range, 0 to 29, with higher scores indicating greater disability) was compared over the 4 weeks of treatment (primary outcome) and during the 2-week washout period with the use of mixed-effects regression models.
Participants	160
Interventions	Valproate acid and placebo
Outcomes	DRS scores; time of break out and state of epilepsy; brain magnetic resonance imaging scan; the blood concentration of valproate acid
Starting date	2013
Contact information	Hu S Jie, Xijing Hospital hushijie@fmmu.edu.cn hushijie1979@126.com
Notes	ClinicalTrials.gov/show/NCT02027987

DATA AND ANALYSES

Comparison 1. Antiepileptic drug (AED) versus placebo or standard care

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Early seizure	5	987	Risk Ratio (IV, Random, 95% CI)	0.42 [0.23, 0.73]
2 Late seizure	6	1029	Risk Ratio (IV, Random, 95% CI)	0.91 [0.57, 1.46]
3 All-cause mortality	5	1065	Risk Ratio (IV, Random, 95% CI)	1.08 [0.79, 1.46]
4 Any serious event	2	568	Risk Ratio (IV, Random, 95% CI)	1.63 [0.73, 3.66]
5 Skin rash	2	568	Risk Ratio (IV, Random, 99% CI)	1.65 [0.54, 5.04]
6 Sensitivity analysis - early seizure: age of population	4	885	Risk Ratio (IV, Random, 95% CI)	0.36 [0.21, 0.60]
7 Sensitivity analysis - early seizure: study quality	2	506	Risk Ratio (IV, Random, 95% CI)	0.48 [0.11, 2.18]
8 Subgroup: late seizure: type of AED	6	1029	Risk Ratio (IV, Random, 95% CI)	0.91 [0.57, 1.46]
8.1 Late seizure - phenytoin	4	752	Risk Ratio (IV, Random, 95% CI)	0.83 [0.40, 1.70]
8.2 Late seizure - other AED	2	277	Risk Ratio (IV, Random, 95% CI)	0.96 [0.46, 1.99]
9 Subgroup - late seizure: treatment duration	6	1029	Risk Ratio (IV, Random, 95% CI)	0.91 [0.57, 1.46]
9.1 Long treatment duration	5	943	Risk Ratio (IV, Random, 95% CI)	1.08 [0.81, 1.46]
9.2 Short treatment duration	1	86	Risk Ratio (IV, Random, 95% CI)	0.14 [0.03, 0.55]
10 Sensitivity analysis - late seizure: age of population	5	706	Risk Ratio (IV, Random, 95% CI)	0.81 [0.44, 1.48]
11 Sensitivity analysis - late seizure: comparison group	5	903	Risk Ratio (IV, Random, 95% CI)	0.83 [0.48, 1.41]
12 Sensitivity analysis - late seizure: study quality	1	323	Risk Ratio (IV, Fixed, 95% CI)	1.25 [0.79, 1.96]
13 Subgroup Analysis - all-cause mortality: age of population	5		Risk Ratio (IV, Random, 95% CI)	Subtotals only
13.1 All-cause mortality - children only	2	143	Risk Ratio (IV, Random, 95% CI)	0.54 [0.25, 1.19]

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
13.2 All-cause mortality - adults and children	2	315	Risk Ratio (IV, Random, 95% CI)	1.43 [0.90, 2.27]
13.3 All-cause mortality - adults only	1	404	Risk Ratio (IV, Random, 95% CI)	1.13 [0.78, 1.62]
14 Subgroup analysis - all-cause mortality: treatment duration	5		Risk Ratio (IV, Random, 95% CI)	Subtotals only
14.1 All-cause mortality - short-term treatment duration	2	346	Risk Ratio (IV, Random, 95% CI)	0.69 [0.39, 1.24]
14.2 All-cause mortality - long-term treatment duration	3	719	Risk Ratio (IV, Random, 95% CI)	1.24 [0.93, 1.65]
15 Sensitivity analysis - all-cause mortality: type of AED	4	914	Risk Ratio (IV, Random, 95% CI)	0.97 [0.65, 1.43]
16 Sensitivity analysis - all-cause mortality: study quality	2	506	Risk Ratio (IV, Fixed, 95% CI)	1.00 [0.72, 1.41]

Analysis 1.1. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 1 Early seizure.

Analysis 1.2. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 2 Late seizure.

Analysis 1.3. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 3 All-cause mortality.

Analysis 1.4. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 4 Any serious event.

Analysis 1.5. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 5 Skin rash.

Analysis 1.6. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 6 Sensitivity analysis - early seizure: age of population.

Analysis 1.7. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 7 Sensitivity analysis - early seizure: study quality.

Analysis 1.8. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 8 Subgroup: late seizure: type of AED.

Analysis 1.9. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 9 Subgroup - late seizure: treatment duration.

Analysis 1.10. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 10 Sensitivity analysis - late seizure: age of population.

Analysis 1.11. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 11 Sensitivity analysis - late seizure: comparison group.

Analysis 1.12. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 12 Sensitivity analysis - late seizure: study quality.

Analysis 1.13. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 13 Subgroup Analysis - all-cause mortality: age of population.

Analysis 1.14. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 14 Subgroup analysis - all-cause mortality: treatment duration.

Analysis 1.15. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 15 Sensitivity analysis - all-cause mortality: type of AED.

Analysis 1.16. Comparison 1 Antiepileptic drug (AED) versus placebo or standard care, Outcome 16 Sensitivity analysis - all-cause mortality: study quality.

Comparison 2. Neuroprotective agent versus placebo

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Early seizure	1		Risk Ratio (IV, Random, 95% CI)	Totals not selected
2 Late seizure	1	498	Risk Ratio (IV, Random, 95% CI)	1.07 [0.53, 2.17]
3 All-cause mortality	1	466	Risk Ratio (IV, Random, 95% CI)	1.2 [0.80, 1.81]

Analysis 2.1. Comparison 2 Neuroprotective agent versus placebo, Outcome 1 Early seizure.

Analysis 2.2. Comparison 2 Neuroprotective agent versus placebo, Outcome 2 Late seizure.

Analysis 2.3. Comparison 2 Neuroprotective agent versus placebo, Outcome 3 All-cause mortality.

Comparison 3. Antiepileptic drug (AED) versus other AED

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1 Early seizure	2	431	Risk Ratio (IV, Random, 95% CI)	0.66 [0.20, 2.12]
2 Late seizure	2	378	Risk Ratio (IV, Random, 95% CI)	0.77 [0.46, 1.30]
3 All-cause mortality	2	431	Risk Ratio (IV, Random, 95% CI)	0.53 [0.30, 0.94]

Analysis 3.1. Comparison 3 Antiepileptic drug (AED) versus other AED, Outcome 1 Early seizure.

Analysis 3.2. Comparison 3 Antiepileptic drug (AED) versus other AED, Outcome 2 Late seizure.

Analysis 3.3. Comparison 3 Antiepileptic drug (AED) versus other AED, Outcome 3 All-cause mortality.

Other _____

Check off inclusion criteria:

Study is an RCT or a quasi-randomized trial.

Patients were diagnosed with TBI.

Study involves administration of pharmacologic agents for the prevention of post-traumatic epilepsy.

Study excluded patients that had a previous documented unprovoked seizure.

Study reports outcomes of interest.

Additional notes:

Part I: Data extraction form

2. General study design questions

Was this a multicenter study?	Not reported
	Yes
	No
Duration of enrolment:	
Duration of follow-up:	
Study excluded patients six years and under?	Not reported
	Yes
	No (indicate details in part 3: Participants)

3. Participants

	Overall	Control	Treatment 1	Treatment 2
N number randomized				
N number followed up				
Age classification:	All patients are < 17 yrs	All patients are < 17 yrs	All patients are < 17 yrs	All patients are < 17 yrs
	All patients are >= 17	All patients are >= 17	All patients are >= 17	All patients are >= 17
	Neither of the above.	Neither of the above.	Neither of the above.	Neither of the above.
Indicate age:

4. Treatment/Control/Comparison

	Control	Treatment 1	Treatment 2
Type of agent	Placebo Usual care	Traditional AED Newly licensed AED Other agent	Traditional AED Newly licensed AED Other agent
Examples for types of agent:	Traditional antiepileptic: antiepileptic Drug that has been on the market for many years (E.g. Carbamazepine, phenytoin, valproate) Newly licensed AED: antiepileptic Drug that has been licensed more recently (E.g. Levetiracetam, topiramate, lamotrigine, oxcarbazepine) Other agent: Any agent or drug that is not marketed as an AED (E.g. Magnesium sulphate)		
Name of agent			
Dose amount & administration method			
Therapeutic dose			
Timing of doses			

(Continued)

Duration of treatment	Short-term	Short-term	Short-term
	Mid-term	Mid-term	Mid-term
	Long-term	Long-term	Long-term
	Additional comment:	Additional comment:	Additional comment:

Definitions for duration of treatment:	Short-term: Treatment less than or equal to 3 months post injury
	Mid-term: Treatment less than or equal to 12 months post injury
	Long-term: Treatment more than 12 months post injury

First dose given before a first posttraumatic seizure?	Not reported	Not reported	Not reported
Yes	Yes	Yes	Yes
No	No	No	No

5. Primary outcomes

For the purpose of this review, seizure outcomes are classified according to the following definitions:

Early seizures are those that occur within one week of trauma.

Late seizures are those that occur later than one week post-trauma.

Note that some studies only report seizure incidence in general and do not indicate when they occurred. Report this in the row labelled "Patients experiencing seizures (general)".

	Control (n/N)	Treatment 1 (n/N)	Treatment 2 (n/N)
Patients experiencing early seizures *			
Patients experiencing late seizures			
Patients experiencing seizures (general)			

* If the study reports actuarial percentages, please note that here.

6. Secondary outcomes

	Control	Treatment 1	Treatment 2

(Continued)

Mortality from any cause during follow-up period

Mean number of early seizures (per patient)

Mean number of late seizures (per patient)

Mean number of seizures (general) (per patient)

Time to first seizure

(may report hazard ratio, CI)

Time to second seizure

(hazard ratio, CI)

Other adverse effects (Eg. Skin rashes)

(Define adverse effect and indicate incidence) (n/N)

**Number of patients for which treatment was discontinued
(include reasons) (n/N)**

Other outcomes reported by study (e.g. Neurological findings, Status Epilepticus)

Part II: Questions for assessing Risk of Bias (ROB)

A summary of the ROB domains, as described by the Cochrane Collaboration in chapter 8 of the handbook, are included here for reference.

Domain	Support for judgement
--------	-----------------------

(Continued)

Selection bias.

Random sequence generation.	Describe the method used to generate the allocation sequence in sufficient detail to allow an assessment of whether it should produce comparable groups.
------------------------------------	--

Allocation concealment.	Describe the method used to conceal the allocation sequence in sufficient detail to determine whether intervention allocations could have been foreseen in advance of, or during, enrolment.
--------------------------------	--

Performance bias.

Blinding of participants and personnel <i>Assessments should be made for each main outcome (or class of outcomes).</i>	Describe all measures used, if any, to blind study participants and personnel from knowledge of which intervention a participant received. Provide any information relating to whether the intended blinding was effective.
---	---

Detection bias.

Blinding of outcome assessment <i>Assessments should be made for each main outcome (or class of outcomes).</i>	Describe all measures used, if any, to blind outcome assessors from knowledge of which intervention a participant received. Provide any information relating to whether the intended blinding was effective.
---	--

Attrition bias.

Incomplete outcome data <i>Assessments should be made for each main outcome (or class of outcomes).</i>	Describe the completeness of outcome data for each main outcome, including attrition and exclusions from the analysis. State whether attrition and exclusions were reported, the numbers in each intervention group (compared with total randomized participants), reasons for attrition/exclusions where reported, and any re-inclusions in analyses performed by the review authors.
--	--

Reporting bias.

Selective reporting.	State how the possibility of selective outcome reporting was examined by the review authors, and what was found.
-----------------------------	--

Other bias.

Other sources of bias.	State any important concerns about bias not addressed in the other domains in the tool. If particular questions/entries were pre-specified in the review's protocol, responses should be provided for each question/entry.
-------------------------------	---

Domain	Assessment	Support for judgement
Selection bias.		
Random sequence generation.	Low Unclear High	

(Continued)

Allocation concealment.	Low
	Unclear
	High

For performance bias, detection bias and attrition bias, assessments should be made for each main outcome (or class of outcomes). Print off more copies of the following page, if more space is required.

Define outcome: _____

Domain	Assessment	Support for judgement
Performance bias.		
Blinding of participants and personnel	Low	
	Unclear	
	High	
Detection bias.		
Blinding of outcome assessment	Low	
	Unclear	
	High	
Attrition bias.		
Incomplete outcome data	Low	
	Unclear	
	High	

(Continued)

Domain	Assessment	Support for judgement
Reporting bias.		
Selective reporting.	Low Unclear High	
Other bias.		
Other sources of bias.	Low Unclear High	

Part III. Additional details

Fill in any study shortcomings and other relevant details.

Appendix 8. Severity of trauma

Mild	Moderate	Severe	Very severe
PTA < 1 hour	PTA 1-24 hours	PTA 1-7 days	PTA > 7 days

(Continued)

GCS 13-15	GCS 9-12	GCS 3-8	LOC > 48 hours
LOC < 15 minutes	LOC < 6 hours	LOC 6-48 hours	

GCS: Glasgow Coma Score; LOC: loss of consciousness; PTA: post-traumatic amnesia.

CONTRIBUTIONS OF AUTHORS

KT initiated the topic.

KT, BP and LA all contributed to drafting of the protocol.

Tracey Daley along with the Cochrane Epilepsy Group Trials Search Co-ordinator devised the search strategy and carried out the literature searches.

KT, BP and LA reviewed and approved protocol.

KT, HA and BP all contributed to the data extraction, and drafted, reviewed and approved the text.

DECLARATIONS OF INTEREST

Leslie Anne Campbell and Bernhard Pohlmann-Eden were supported by a Nova Scotia Health Research Foundation Knowledge Programs Grant.

Bernhard Pohlmann-Eden is a member of the Advisory Board of UCB Pharma. He has also acted as a consultant for UCB Pharma Canada. Berhard has received speaker's honoraria from UCB Pharma and Desitin Pharam Germany on several occasions.

Kara Thompson is a Biostatistician for the Department of Medicine, therefore, additional funding received from Nova Scotia Health Research Foundation was to provide a research assistant to help with work on project.

Hannah Abel provided research assistance in the review.

SOURCES OF SUPPORT

Internal sources

- Research Office, Department of Medicine, Dalhousie University, Canada.
- Research Methods Unit, CDHA, Canada.

External sources

- Nova Scotia Health Research Foundation's (NSHRF) Systematic Review grant, Canada.

Funding was provided for research assistant.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We found too few studies; therefore, we produced no funnel plots or orbit tables. Other sources of bias were also considered in addition to the bias domains listed in protocol. We performed no subgroup analysis by trauma severity as only one study reported including participants of moderate to severe trauma, all the other studies included severe only. The subgroup analyses for age were broken down by proportion of participants aged over 17 years and under 17 years, such that studies that exclusively included adults or exclusively children were separated out. Data were not provided in a manner that we were able to separate by mean age under six years, age between six and 17 years and age over 17 years as planned in protocol. We performed no subgroup analysis for the early seizure outcome due to insufficient data. However, we added a sensitivity analysis for age of population for early seizure. Subgroup analysis was only performed by type of AED and treatment duration for the late seizure outcome due to insufficient data for other analyses. We added a sensitivity analysis for age of population, and type of control group (placebo versus usual care) comparison for late seizure. Insufficient data were available to perform a subgroup analysis by type of AED for all-cause mortality; however, we performed a sensitivity analysis. Time-to-event data were not provided in the papers; therefore, we did not use hazard ratios to summarize time-to-event outcomes. Time from first seizure to second seizure was not recorded or analyzed as these data were not provided in the papers. No trial reported comparing a pharmacologic agent other than an AED with a placebo on adverse events; therefore, we completed no analysis. We performed no imputation for missing data, as this was not relevant based on data collected. We performed no sensitivity analysis for analysis based on imputation.

INDEX TERMS**Medical Subject Headings (MeSH)**

Anticonvulsants [*therapeutic use]; Carbamazepine [therapeutic use]; Cause of Death; Craniocerebral Trauma [*complications] [mortality]; Epilepsy [etiology] [mortality] [*prevention & control]; Levetiracetam; Magnesium Sulfate [therapeutic use]; Neuroprotective Agents [*therapeutic use]; Phenytoin [therapeutic use]; Piracetam [analogs & derivatives] [therapeutic use]; Randomized Controlled Trials as Topic; Valproic Acid [therapeutic use]
