Background: ADP ribosylation factor 6 (ARF6) is a member of the Rat sarcoma virus (RAS) superfamily that is involved in the regulation of vesicular trafficking, membrane lipid remodeling, and signaling pathways. Our earlier work discovered that ARF6, as a downstream effector of the Kirsten rat sarcoma viral oncogene (Kras)/extracellular signal-regulated kinases (ERK) signaling pathway, may increase proliferation and induce the Warburg effect in gastric cancer (GC) cells. Additionally, ARF6 appears to be a potential biomarker for predicting the prognosis of GC. Ferroptosis has recently been described as a type of nonapoptotic iron-dependent cell death that is strongly associated with the Kras mutation. Therefore, it is critical to continue investigating the link between ARF6 and ferroptosis.

Methods: We first created ARF6 silenced cancer cell lines with lentivirus transfection. The knockdown efficiency was confirmed through quantitative polymerase chain reaction (qPCR) and western blotting. Subsequently, we used Cell Counting Kit-8 (CCK-8) and malondialdehyde (MDA) assay for lipid peroxidation measurement. Following this, qPCR and western blotting were conducted to clarify the mechanism involved. Finally, immunohistochemistry was used to stain human GC samples.

Results: Our findings established that, whereas ARF6 did not directly regulate lipid peroxidation, it did render GC cells susceptible to oxidative stress, particularly erastin-induced lipid peroxidation. Additionally, our research demonstrated that ARF6 may control capecitabine resistance via several routes.

Conclusions: ARF6 may play a critical role in the development of GC.

Introduction

Discovered in 2012, ferroptosis is an iron-dependent form of nonapoptotic-mediated cell death (1,2). Studies have shown that ferroptosis differs from other well-known forms of cell death, such as apoptosis, necrosis, and autophagy, in terms of morphology, biochemistry, and genetics (3-5). Unlike apoptosis, ferroptosis is induced by the deficiency of glutathione (GSH) or the inactivation of glutathione

peroxidase 4 (GPX4) function (6,7). In addition, during ferroptosis, unique changes in mitochondrial morphology occur, mainly the loss of structural integrity, which manifests, for instance, in smaller than normal mitochondria, condensation of mitochondrial membrane density, reduction or disappearance of mitochondrial cristae (8), and the rupture of the outer mitochondrial membrane (9). Ferroptosis is hypothesized to be caused by an excessive iron-dependent accumulation of lipid peroxidation products. Therefore,

small-molecule lipophilic antioxidants and iron chelators may be able to prevent ferroptotic cell death, a role that the other types of cell death inhibitors outlined above cannot perform. Erastin, a ferroptosis inducer, was found to improve the efficacy of a few chemotherapeutic drugs for breast cancer and brain cancer, such as temozolomide, cisplatin, cytarabine/ARA-C, and doxorubicin/adriamycin (10-12). These findings show that activating ferroptosis in cancer patients may be a unique approach in treatment. Additionally, a number of US Food and Drug Administration (FDA)-approved therapeutic drugs, including sorafenib and sulfapyridine, have been shown to elicit ferroptosis in a variety of cancer cells, demonstrating the feasibility of ferroptosis in preclinical and clinical settings.

Gastric cancer (GC) is one of the most common types of cancer in the world, ranking fifth in terms of incidence and fourth in terms of fatality in 2020. Furthermore, GC has the greatest incidence of gastrointestinal cancers, with high cancer-related mortality rates being reported in east Asia, including China (13-15). The prognosis for individuals with GC has improved significantly over the last few decades as a result of comprehensive treatment that includes curative surgery, chemoradiotherapy, targeted therapy, and immunotherapy. However, the majority of patients are detected at an advanced stage, with a 5-year overall survival rate of less than 40% (15-17). Regarding GC therapy, a previous study has established the critical role of ferroptosis in the treatment and prognosis of GC, which includes the facilitation of perilipin 2 in regulating the proliferation and apoptosis of gastric carcinoma cells through intervening in the ferroptosis pathway (18). Moreover, little literatures explored the relationship between ferroptosis and GC. Therefore, it is urgent to investigate the underlying effect of ferroptosis on GC and the promising value on cancer therapy.

ADP ribosylation factor 6 (ARF6) belongs to the Rat sarcoma virus (RAS) superfamily and encodes small guanine nucleotide-binding proteins (GTP-binding protein). ARF6 is involved in a variety of cellular processes, including autophagy support, lipid-modifying enzyme activation, increase of actin polymerization, and innate immunity (13). Additionally, ARF6 has been shown to influence cancer cell invasion, metastasis, and proliferation (14). Notably, ARF6 has been found to direct downstream transport and recycling of cargo following clathrin-mediated and clathrin-independent endocytosis (15,16). These results suggest that ARF6 may play a variety of roles in cell physiology by

regulating the breakdown and recycling of a diversity of functional proteins. One study indicated that the Kirsten rat sarcoma viral oncogene (Kras)/extracellular signal-regulated kinases (ERK) pathway might stimulate ARF6, resulting in the formation of a positive feedback loop between ARF6 and c-myc, which in turn could promote GC proliferation and induce the Warburg effect (17). According to a recent study, c-myc may prevent ferroptosis via modulating the expression of lipid metabolic genes (18). If Kras and c-myc both regulate ferroptosis, it is critical to determine whether ARF6, the protein that connects Kras and c-myc, regulates ferroptosis and what effect this regulation has on the development of GC.

In this study, we investigated the potential impact of ARF6 on ferroptosis in GC cells. We found that ARF6 did not directly regulate the generation of lipid peroxidation, but did affect the sensitivity of erastin-induced ferroptosis. Further results revealed that ARF6 aggravated capecitabine by inhibiting ferroptosis and capecitabine-related metabolic proteins, DCK and hENT1. We present the following article in accordance with the MDAR reporting checklist (available at <https://jgo.amegroups.com/article/view/10.21037/jgo-22-341/rc>).

Methods

Ethical statement

The study was conducted in accordance with the Declaration of Helsinki (as revised in 2013). The study was approved by Ethics Committee of Shengjing Hospital of China Medical University (No. JC20200935) and informed consent was taken from all the patients.

Cell culture

Human gastric mucosal epithelial cell line GES-1 and human GC cell lines SGC-7901, BGC-823, AGS, MKN-45, SNU-1, and MGC80-3 were obtained from the American Type Culture Collection (ATCC) and cultured according to standard ATCC protocols. In brief, SGC-7901, BGC-823, and AGS cells were cultured in Dulbecco's Modified Eagle's Medium (DMEM) containing 10% fetal bovine serum (FBS); MKN-45 and SNU-1 cells were cultured in 1640 medium containing 10% FBS; GES-1 cells were cultured in Leibovitz (L-15) containing 10% FBS; and MGC80-3 cells were cultured in DMEM medium, with 10% FBS, 2.5% horse serum, and 1% sodium pyruvate.

RNA isolation and quantitative real-time polymerase chain reaction (qRT-PCR)

Total RNA was extracted using TRIzol reagent (Invitrogen, Waltham, MA, USA). qRT-PCR was conducted as described previously (19). All the reactions were completed in triplicate.

The following primers were used: human ARF6: 5'-ATTACTACACCGGGACCCAGGGTCT-3' (forward), 5'-AGGTCCTGCTTGTTGGCGAAGATG-3' (reverse); human ACSL4: 5'-CTGTTTCAGCGTTTTGCAAGGTA-3' (forward), 5'-TAGTGGCATCTCCCTGGTCC-3' (reverse); human hENT1: 5'-CCGGATGCTCACTCCAAAGT-3' (forward), 5'-AATAACAGCAGGGGCAGCAT3' (reverse); Human DCK: 5'-TCCATCGAAGGGAACATCGC-3' (forward), 5'-CAGTGTCCTATGCAGGAGCC-3' (reverse); and human β -actin: 5'-CTACGTCGCCCTGGACTTCGAGC-3' (forward), 5'-GATGGAGCCGCCGATCCACACGG-3' (reverse).

Western blotting analysis

Western blotting analysis was performed as previously described (19). Antibodies against ACSL4, GPX4, and SCD1 were acquired from Abcam (Cambridge, UK). Antibodies against-actin, hENT1, FSP1, DCK, and RRM1 were acquired from Proteintech (Rosemont, IL, USA).

Lentivirus production

The pLKO.1 TRC cloning vector (Addgene plasmid: 10887) was used to produce short hairpin RNA (shRNA) expression constructs against ARF6 in a manner described previously (17). 5'-GCTCACATGGTTAACCTCTAA-3' and 5'-CAACAATCCTGTACAAGTTGA-3' were used as targets (21 bp) against ARF6. To create lentiviral particles, pLKO.1-constructs, psPAX2 and pMD2.G, were cotransfected into HEK-293T cells.

Small compounds

Erastin (Ab15763), ROSI (Ab17386), OA (Ab1446), and capecitabine (Ab17026) were purchased from Abcam.

Cell viability

Cell Counting Kit-8 (CCK-8; Beyotime Beijing, China) was

used to detect cell viability according to the manufacturer's instructions.

Lipid peroxidation assay

BODIPYTM 581/591 C11 was used to detect lipid peroxidation (D3861; Thermo Fisher Scientific, Waltham, MA, USA). In brief, cells were trypsinized and then resuspended in 400 μ L of serum-free medium with BODIPYTM 581/591 C11 (2 μ M). Following this, cells were incubated at 37 $^{\circ}$ C for 30 minutes in a cell culture incubator. The samples were subsequently analyzed using a flow cytometer, with the data being gathered from the FL1 channel. A minimum of 10,000 cells were evaluated for each condition. Additionally, BODIPYTM 581/591 C11 (2 μ M) was incubated directly in adherent cultivated cells for 30 minutes at 37 $^{\circ}$ C, and the fluorescence was detected using confocal microscopy.

Malondialdehyde (MDA) assay

MDA was detected using the Lipid Peroxidation MDA Assay Kit (BC0025; Beijing Solarbio Science & Technology Co., Ltd, Beijing, China), according to the manufacturer's instructions.

Immunohistochemical (IHC) staining

Clinical tissue samples were gathered with from patients diagnosed with GC at Shengjing Hospital of China Medical University. Antibodies against ARF6 and ACSL4 were used to stain paraffin-embedded tissues using normal IHC methods. Anti-ACSL4 (ab155282; Abcam) and anti-ARF6 (ab77581; Abcam) antibodies were employed at a 1:100 dilution factor. Positive proportion and intensity were quantified semiquantitatively in a manner described previously (20).

Statistical analyses

All experiments were performed independently a minimum of 3 times. All statistical analyses were performed using SPSS v. 24.0 (IBM Corp, Armonk, NY, USA). Within-group comparisons were carried out using a paired *t*-test, while between group-comparisons were carried using an unpaired *t*-test; differences were considered significant at $P < 0.05$ and $P < 0.01$, respectively.

Results

Knockdown of ARF6 enhanced erastin-induced ferroptosis

To choose the appropriate cell lines for further investigation, we determined the quantity of ARF6 protein in a human gastric duct epithelial cell line (GES-1) and numerous GC cell lines. Our findings indicated that ARF6 was expressed at a reasonably high level in the BGC-823 and MGC80-3 cell lines (Figure 1A). As a result, we generated stable shRNA expression in each of the BGC-823 and MGC80-3 cell lines. qRT-PCR and western blotting were used to confirm the knockdown efficiency (Figure 1B,1C). To determine whether ARF6 can regulate ferroptosis in GC cells, we assessed their sensitivity to 2 well-characterized ferroptosis inducers, erastin. Indeed, silencing ARF6 sensitized the BGC-823 and MGC80-3 cell lines significantly to the ferroptosis produced by erastin, but not that produced by erastin (Figure 1D). These findings suggested that ARF6 could regulate the ferroptosis caused by erastin in GC cells.

ARF6 did not cause lipid peroxidation but enhanced erastin-induced lipid peroxidation

Because lipid peroxidation is a critical part of ferroptosis, we measured the quantity of MDA, which is a product of lipid peroxidation. Intriguingly, silencing ARF6 had no effect on the MDA level in either the BGC-823 or MGC80-3 cell

lines, but this did increase the level of erastin-induced MDA (Figure 2A,2B). Following this, we tested a fluorescent probe to identify the oxidized lipids directly. When this probe attaches to oxidized lipids, the fluorescence appears green. Confocal scanning imaging confirmed that erastin increased the amount of oxidized lipids in ARF6-knockdown cells (Figure 2C).

ARF6 regulated the lipid peroxidation sensitivity to erastin via GPX4

Since erastin directly targets GPX4 and our findings suggest that ARF6 has an effect on the severity of lipid peroxidation produced by erastin, we then examined whether ARF6 is involved in the regulation of GPX4 expression. The results showed that the level of GPX4 protein was increased in ARF6-knockdown cells (Figure 3A). Moreover, after erastin stimulation, ARF6-knockdown cells exhibited a significant increase in GPX4 messenger RNA (mRNA) (Figure 3B). We then aimed to determine whether ARF6 has an effect on erastin sensitivity via the inhibition of ACSL4. The subsequent experiments demonstrated that the knockdown of ARF6 significantly reduced the downregulation of GSH after erastin stimulation (Figure 3C). Furthermore, cells in which ARF6 was knocked down showed lower elevation of reactive oxygen species (ROS) after erastin stimulation (Figure 3D). GSH, ROS, and lipid peroxidation are significant markers

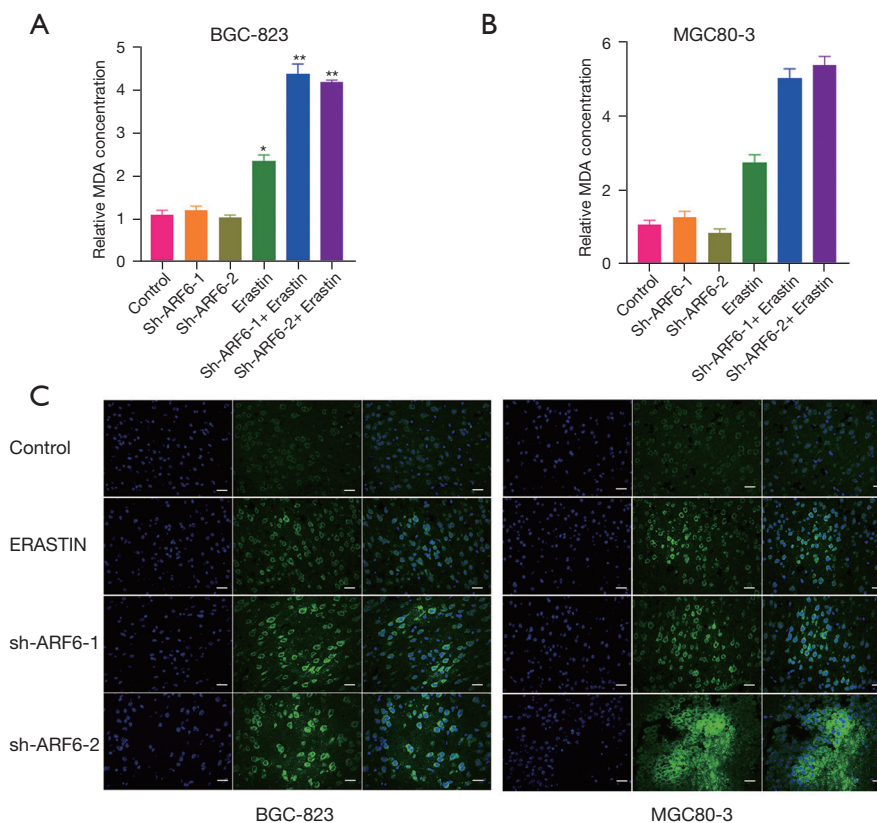

Figure 2 Knocked down ARF6 only initiated lipid peroxidation when erastin was present. (A) MDA levels were determined in AR6-silenced BGC-823 cells both treated and not treated with erastin (2 μ M). (B) MDA levels were determined in AR6-silenced MGC80-3 cells both treated and not treated with erastin. (C) Confocal imaging ($\times 40$) revealed nuclear (blue) and oxidized (green) lipids in the ARF6-silenced BGC-823 and MGC80-3 cells both treated and not treated with erastin (2 μ M) and stained with DAPI. *, $P < 0.05$; **, $P < 0.01$. of ferroptosis, and our experiments soundly confirmed that knockdown of ARF6 reduced the extent to which erastin induced ferroptosis in the GC cell lines.

ARF6 regulated capecitabine resistance in GC cells

Research indicates that capecitabine may also promote oxidative stress and raise the quantity of ROS in GC cells (21). The purpose of this study was to confirm if capecitabine can promote lipid oxidation. Intriguingly, as the capecitabine concentration was increased, the degree of lipid oxidation increased slightly (Figure 4A). Given that ARF6 has been shown to regulate erastin-induced lipid peroxidation, we next investigated whether ARF6 can regulate capecitabine-induced lipid peroxidation. Surprisingly, silencing ARF6 improved capecitabine-induced MDA concentrations (Figure 4B). Additionally, we

examined the capecitabine sensitivity of the BGC-823 and MGC80-3 cell lines to capecitabine. The results indicated that silencing ARF6 significantly reduced capecitabine resistance (Figure 4C, 4D). This prompted us to consider the possibility of ARF6 regulating capecitabine resistance via other routes. We thus examined numerous metabolic proteins associated with capecitabine resistance, including dihydropyrimidine dehydrogenase (DPD) and thymidylate synthase (TS). Our results indicated that silencing ARF6 significantly lowered the levels of TS and DPD (Figure 4E, 4F). This may account for the repair of capecitabine sensitivity caused by ARF6 silencing.

ARF6 and GPX4 expression was negatively correlated in patients with GC

We randomly selected 42 patients diagnosed with GC in

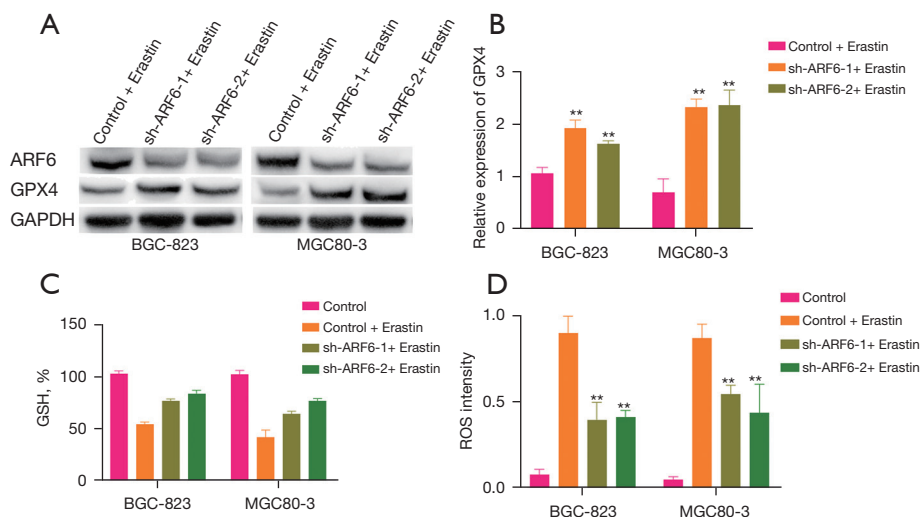

Figure 3 ARF6 regulated sensitivity to RSL3 via GPX4. (A) Western blotting was used to determine the expression of ARF6 and GPX4 in BGC-823 and MGC80-3 cells that were both silenced and not silenced by ARF6. (B) qRT-PCR was used to determine whether GPX4 was suppressed in the BGC-823 and MGC80-3 cells. (C,D) GSH and ROS levels in BGC-823 and MGC80-3 both silenced and not silenced for ARF6 were detected after an erastin cascade. **, $P < 0.01$. our center to determine the expression status of ARF6 and GPX4 in their tissues. We subsequently stained their paraffin-embedded tissues with antibodies against ARF6 and GPX4 using IHC. Additionally, we generated ARF6 and GPX4 IHC values by multiplying the proportion and intensity scores. *Figure 5A* presents 2 typical examples of ARF6 and GPX4 expressions that are diametrically opposed. We conducted a statistical study of the correlation between ARF6 and GPX4, and discovered a substantial negative correlation between ARF6 and GPX4 in patients with GC (*Figure 5B*).

Discussion

Ras superfamily members are required for normal cellular function, and their mutations or aberrant activation promotes cancer formation (22,23). On the basis of sequence identity and function, the Ras superfamily can be separated into 5 distinct families: Ras, Rho, Rab, Arf, and Ran (24). RAS (KRAS, HRAS, NRAS) is the most frequently mutated oncogene in human cancer, occurring most frequently in gastric, colon, and lung malignancies. Furthermore, RAS mutations are associated with a poor prognosis and resistance to therapy, while there are currently no effective medicines for tumors that express mutant versions of the RAS oncoprotein (25). As a result, it is critical to identify chemicals

that are specifically deleterious to RAS-mutant tumor cells. To this end, researchers examined tens of thousands of chemicals in order to identify those that were capable of killing RAS mutant cancer cells. Those that were eventually discovered as suitable (including erastin) were dubbed RAS-selective lethal (RSL) compounds, and their underlying mechanisms were described in further detail. Additionally, the researchers discovered that these chemicals destroyed cells in a novel, iron-dependent manner that was distinct from apoptosis (3,4). This type of cell death was further described in 2012, characterized by iron dependency and lipid peroxidation, and consequently named *ferroptosis* (26). Erastin is one of the classic inducers of ferroptosis, as it inhibits the Na^+ -independent cystine/glutamate antiporter (system xc^-) and specifically targets GPX4 (27).

ARF6, one of several members of the integrin superfamily, has a significant and intricate effect on cells. However, the link between ARF6 and ferroptosis is not well understood. We discovered that ARF6 suppressed sensitized erastin-induced ferroptosis; although the process through which this occurs remains unclear. It is possible that in GC, an active trans-sulfuration mechanism is present that can counteract the erastin-induced cystine shortage (28). However, additional research is required to verify this. We then demonstrated that silencing ARF6 had no effect on the degree of lipid peroxidation, which is the primary hallmark

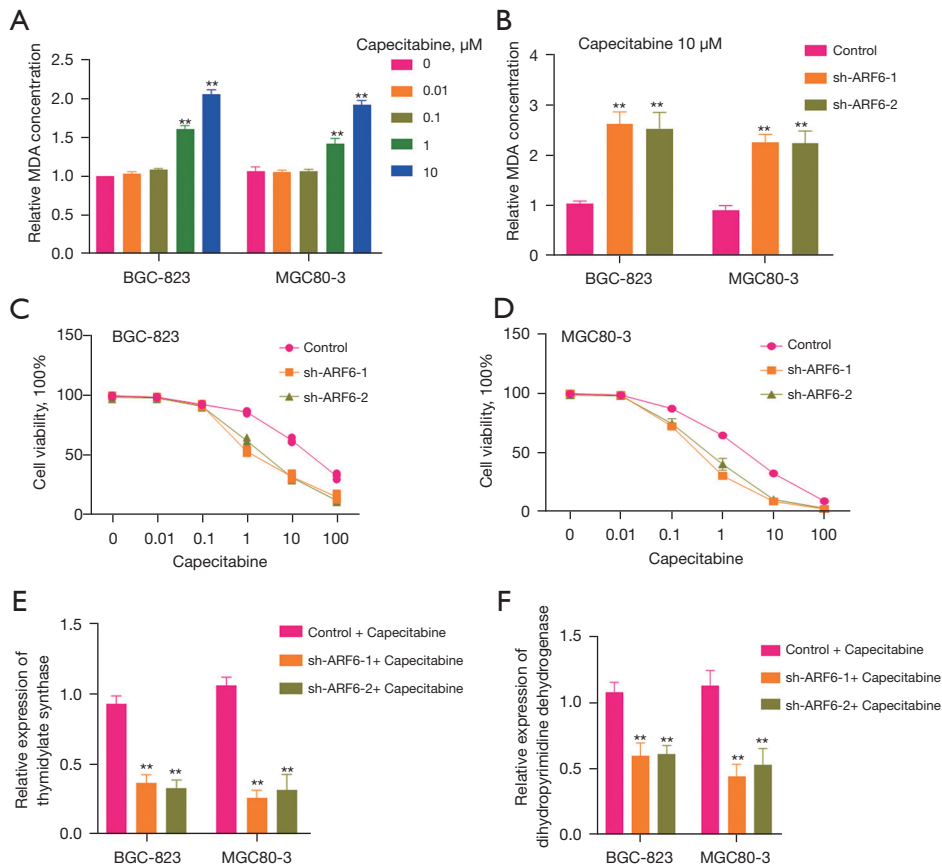

Figure 4 In gastric cancer cells, ARF6 modulated capecitabine resistance. (A) After 2 days of pretreatment with capecitabine at a variety of doses in the BGC-823 and MGC80-3 cells, the MDA level was measured. (B) Capecitabine (10 μM) was pretreated or not pretreated in ARF6-silenced BGC-823 and MGC80-3 cells, and the MDA level was measured. (C,D) The dose-dependent toxicity of capecitabine was determined in ARF6-deficient BGC-823 and MGC80-3 cells. (E,F) qRT-PCR was used to determine the influence of ARF6 on the level of TS and DPD mRNA. **, $P < 0.01$. ARF6, ADP ribosylation factor 6; MDA, malondialdehyde; qRT-PCR, quantitative real-time polymerase chain reaction; TS, thymidylate synthase; DPD, dihydropyrimidine dehydrogenase.

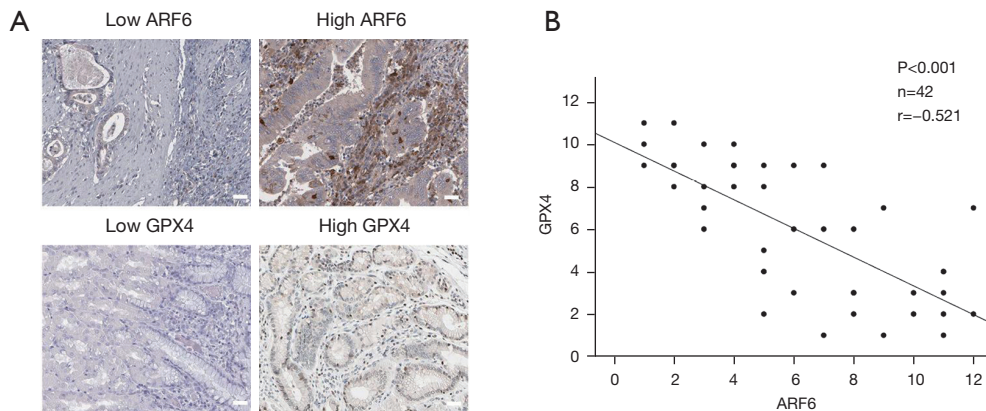

Figure 5 In gastric cancer patients, ARF6 expression was adversely linked with GPX4 expression. (A,B) Representative micrographs (immunohistochemistry for ARF6 protein, $\times 40$) demonstrating the proportional and intensity scores for ARF6 and GPX4, respectively. of ferroptosis. Surprisingly, ARF6 suppressed erastin-induced peroxidation. Further investigation indicated that silencing ARF6 increased the level of GPX4 protein and mRNA. These results suggest that ARF6 may be able to regulate GPX4 at the posttranslational stage. ACSL4 has been shown to control the sensitivity of erastin- or GPX4-depleted ferroptosis by modifying the cellular lipid composition to one that can be easily oxidized.

Ferroptosis offers a wide range of clinical applications. For example, it has been demonstrated that drug-resistant cancer cells are susceptible to ferroptosis (29). One study has been conducted in this area with the goal of employing nanomaterials as drug carriers to deliver ferroptosis inducers to cancer cells *in vivo* (30). Additionally, blocking or activating ferroptosis has been found capable of altering cisplatin sensitivity (31). We thus searched for a link between ARF6-regulated ferroptosis and capecitabine. We discovered that silencing ARF6 increased capecitabine sensitivity in GC, although this impact was not entirely due to ferroptosis activation. The capecitabine-related metabolic proteins, TS and DPD, may also be involved in this process, as ARF6 silencing was also found to increase the TS and DPD mRNA levels.

Some limitations to this study should be noted. First, our study did not specifically examine how ARF6 regulates GPX4. One previous report indicates that ARF6 is localized to the plasma membrane and vesicle membrane in the cytoplasm, where it functions in the internalization of ligands and recycling endosomes, the regulation of endocytic membrane trafficking and actin remodeling, the promotion of autophagy, and other processes (32). Since GPX4 was enriched in plasma membrane, we guessed that ARF6 silenced might inhibit the degradation by decreasing the transport to lysosome, for ARF6 has been reported to determine the destination of the cargo in endosome: to be recycled or to be degraded by lysosome (13).

Conclusions

In conclusion, this study establishes a role for ARF6 in erastin-induced ferroptosis and capecitabine-resistant GC cells and provides a preliminary understanding of the underlying mechanism.
