Abstract

Background: SARS-CoV-2 transmission has been reported to be associated with close contact with infected individuals. However, the mechanistic pathway for transmission in close contact settings is unclear. Our objective was to identify, appraise and summarise the evidence from studies assessing the role of close contact in SARS-CoV-2 transmission.

Methods: This review is part of an Open Evidence Review on Transmission Dynamics of SARS-CoV-2. We conduct ongoing searches using WHO Covid-19 Database, LitCovid, medRxiv, PubMed and Google Scholar; assess study quality based on the QUADAS-2 criteria and report important findings on an ongoing basis.

Results: We included 181 studies: 171 primary studies and 10 systematic reviews. The settings for primary studies were predominantly in home/quarantine facilities (31.6%) and acute care hospitals (15.2%). The overall reporting quality of the studies was low to moderate. There was significant heterogeneity in design and methodology. The frequency of attack rates (PCR testing) was 3.5-75%; attack rates were highest in prison and wedding venues, and in households. The frequency of secondary attack rates was 0.3-100% with rates highest in home/quarantine settings. Three studies showed no transmission if index cases had recurrent infection. Viral culture was performed in three studies of which two found viable virus; culture results were negative where index cases had recurrent infections. Ten studies performed genomic sequencing with phylogenetic analysis – the completeness of genomic similarity

Any reports and responses or comments on the article can be found at the end of the article.

ranged from 81-100%. Findings from systematic reviews showed that children were significantly less likely to transmit SARS-CoV-2 and household contact was associated with a significantly increased risk of infection.
Conclusions: The evidence from published studies demonstrates that SARS-CoV-2 can be transmitted via close contact settings. The risk of transmission is greater in household contacts. There was wide variation in methodology. Standardized guidelines for reporting transmission in close contact settings should be developed to improve the quality reporting.

Competing interests: CJH holds grant funding from the NIHR School of Primary Care Research, the NIHR BRC Oxford and the World Health Organization for a series of Living rapid review on the modes of transmission of SARs-CoV-2 reference WHO registration No2020/1077093. He has received expenses and fees for his media work. He receives expenses for teaching EBM and is also paid for his GP work in NHS out of hours (contract Oxford Health NHS Foundation Trust) and for appraising treatment recommendations in non-NHS settings. He is the Director of CEBM and is an NIHR Senior Investigator. TJ was in receipt of a Cochrane Methods Innovations Fund grant to develop guidance on the use of regulatory data in Cochrane reviews (2015-018). In 2014–2016, he was a member of three advisory boards for Boehringer Ingelheim. TJ was a member of an independent data monitoring committee for a Sanofi Pasteur clinical trial on an influenza vaccine. TJ is occasionally interviewed by market research companies about phase I or II pharmaceutical products for which he receives fees (current). TJ was a member of three advisory boards for Boehringer Ingelheim (2014-16). TJ was a member of an independent data monitoring committee for a Sanofi Pasteur clinical trial on an influenza vaccine (2015-2017). TJ is a relator in a False Claims Act lawsuit on behalf of the United States that involves sales of Tamiflu for pandemic stockpiling. If resolved in the United States' favor, he would be entitled to a percentage of the recovery. TJ is co-holder of a Laura and John Arnold Foundation grant for development of a RIAT support centre (2017-2020) and Jean Monnet Network Grant, 2017-2020 for The Jean Monnet Health Law and Policy Network. TJ is an unpaid collaborator to the project Beyond Transparency in Pharmaceutical Research and Regulation led by Dalhousie University and funded by the Canadian Institutes of Health Research (2018-2022). TJ consulted for Illumina LLC on next generation gene sequencing (2019-2020). TJ was the consultant scientific coordinator for the HTA Medical Technology programme of the Agenzia per i Serivizi Sanitari Nazionali (AGENAS) of the Italian MoH (2007-2019). TJ is Director Medical Affairs for BC Solutions, a market access company for medical devices in Europe. TJ is funded by NIHR UK and the World Health Organization (WHO) to update Cochrane review A122, "Physical Interventions to interrupt the spread of respiratory viruses". TJ is funded by Oxford University to carry out a living review on the transmission epidemiology of COVID-19. Since 2020, TJ receives fees for articles published by The Spectator and other media outlets. TJ is part of a review group carrying out "Living rapid literature review on the modes of transmission of SARS-CoV-2 (WHO Registration 2020/1077093-0)". He is a member of the WHO COVID-19 Infection Prevention and Control Research Working Group. DHE has been awarded U.S. patents as a co-inventor of related oncolytic virus technologies and is a co-owner of Prophysis Inc., which retains a partial interest in the licensing rights for these technologies. JMC holds grants from the Canadian Institutes for Health Research on acute and primary care preparedness for COVID-19 in Alberta, Canada and was the primary local Investigator for a Staphylococcus aureus vaccine study funded by Pfizer for which all funding was provided only to the University of Calgary. He also received support from the Centers for Disease Control and Prevention (CDC) to attend an Infection Control Think Tank Meeting. Annette Plüddemann is Senior Research Fellow at the Centre for Evidence-Based Medicine and reports grant funding from NIHR School of Primary Care Research (NIHR SPCR ESWG project 390 and project 461), during the conduct of the study, and occasionally receives expenses for teaching Evidence-Based Medicine. IJO, EAS and JB have no interests to disclose.

Grant information: The review was funded by the World Health Organization: Living rapid review on the modes of transmission of SARs-CoV-2 reference WHO registration No2020/1077093. CH and ES also receive funding support from the NIHR SPCR Evidence Synthesis Working Group project 390.
The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Introduction

The SARS-CoV-2 (COVID-19) pandemic is a major public health concern. Based on WHO data, there have been over 120 million confirmed cases and over two and a half million deaths globally as of 20th March 2021[1]. Many national governments have implemented prevention and control measures and vaccines are now being approved and administered; the overall global spread of the virus now appears to be slowing. Current evidence from epidemiologic and virologic studies suggest SARS-CoV-2 is primarily transmitted via respiratory droplets and direct and indirect contact[2,3]. However, controversy still exists about how the virus is transmitted and the relative frequency of the modes of transmission and if these modes may be altered in specific settings[4,5].

Although close contact is thought to be associated with transmission of SARS-CoV-2, there is uncertainty about the thresholds of proximity for "close contact" and the factors that may influence the transmission in a "close contact". Furthermore, there is lack of clarity about how research should be conducted in the setting of transmission with close contact which may include transmission via any one of or the combination of respiratory droplets, direct contact, or indirect contact.

Several studies investigating the role of close contact in SARS-CoV-2 transmission have been published but the pathways and thresholds for transmission are not well established. The objective of this review was to identify, appraise and summarize the evidence from primary studies and systematic reviews investigating the role of close contact in the transmission of SARS-CoV-2. Terminology for this article can be found in Box 1.

Box 1. Terminology

Close contact: Someone who was within 6 feet of an infected person for a cumulative total of 15 minutes or more over a 24-hour period starting from 2 days before illness onset (or, for asymptomatic patients, 2 days prior to test specimen collection) until the time the patient is isolated;[1] The World Health Organization (WHO) additionally includes direct physical contact with a probable or confirmed case, direct care for a patient with probable or confirmed COVID-19 disease without using proper PPE, and other situations as indicated by local risk assessments.

Attack rate: The proportion of those who become ill after a specified exposure[2].

Secondary attack rate: The probability that infection occurs among susceptible persons within a reasonable incubation period following known contact with an infectious person or an infectious source[3].

Cycle threshold: The number of cycles required for the fluorescent signal to cross the threshold. Ct levels are inversely proportional to the amount of target nucleic acid in the sample[4].

Methods

We are undertaking an open evidence review examining the factors and circumstances that impact on the transmission of SARS-CoV-2, based on our published protocol last updated on the 1 December 2020 (Version 3: 1 December 2020, *Extended data:* Appendix 1[6]). This review aims to identify, appraise, and summarize the evidence (from peer-reviewed studies or studies awaiting peer review) examining the role of close contact in the transmission of SARS-CoV-2 and the factors that influence transmissibility. We are conducting an ongoing search in WHO Covid-19 Database, LitCovid, medRxiv, and Google Scholar for SARS-CoV-2 for keywords and associated synonyms. For this review, we also conducted searches on PubMed. The searches for this update were conducted up to 20th December 2020 (*Extended data:* Appendix 2[6]). We did not impose any language restrictions.

We included studies of any design that investigated transmission associated with close contact but excluded predictive or modelling studies. We reviewed the results for relevance and for articles that appeared particularly relevant, we undertook forward citation matching to identify relevant results. We assessed the risk of bias of included primary studies using five domains from the QUADAS-2 criteria[7]; we adapted this tool because the included studies were not primarily designed as diagnostic accuracy studies. We did not perform formal assessments of the quality of included systematic reviews but summarized their findings, including quality of their included studies as reported by the authors. We extracted the following information from included studies: study design characteristics including the definition used of "close contact", population, main methods, and associated outcomes including the number of swab samples taken with frequency and timing of samples, and cycle thresholds and samples concentrations. We also extracted information on viral cultures including the methods used. One reviewer (IJO) assessed the risk of bias from primary studies, and these were independently verified by a second reviewer (EAS). One reviewer (IJO) extracted data from the included primary studies, and these were independently checked by a second reviewer (CJH). One reviewer (CJH) extracted data from the included systematic reviews, and these were independently checked by a second reviewer (IJO). Disagreements in the data extraction or bias assessments were resolved by consensus. We presented the results in tabular format, and bar charts used to present the frequency of positive tests. We reported results of specific subgroups of studies where relevant. Because of substantial heterogeneity across the included studies, we considered meta-analyses inappropriate.

Results

We identified 1202 non-duplicate citations of which 229 were considered eligible (Figure 1). We excluded 48 full-text studies for various reasons (see *Extended data:* Appendix 3[6] for the list of excluded studies and reasons for exclusion). Finally, we included 181 studies: 171 primary studies and 10 systematic reviews (see *Extended data:* Appendix 4 for references to included studies). The main characteristics of the included primary studies and systematic reviews are shown in Table 1 and Table 2, respectively.

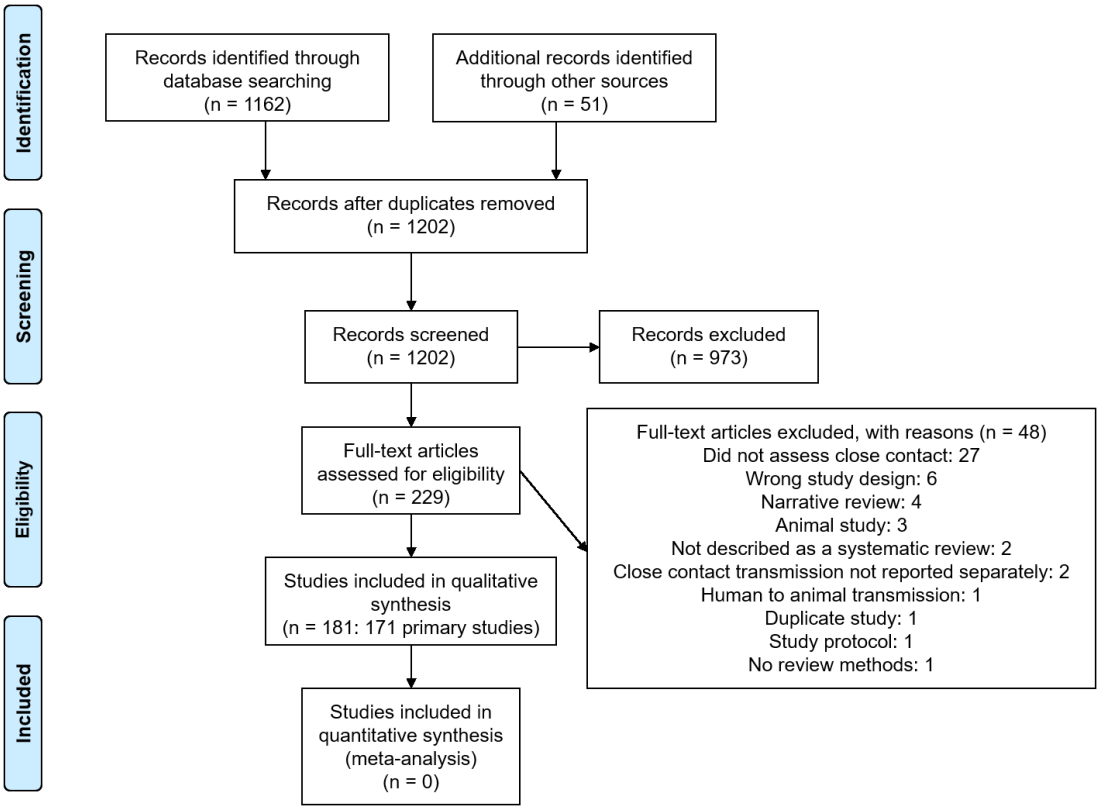

Figure 1. Flow diagram showing the process for inclusion of studies assessing close contact transmission in SARS-CoV-2.

Quality of included studies

None of the included primary studies reported a published protocol except one (Helsingen 2020). The risk of bias of the included primary studies is shown in Table 5. Only 61 studies (35.7%) adequately reported the methods used, and 97 (56.7%) adequately described the sources of sample collection. Only six studies (3.5%) adequately reported methods used to address biases. The overall quality of the studies was judged as low to moderate (see the risk of bias graph in Figure 2).

Reviews

We included 10 systematic reviews investigating the role of close contact in SARS-CoV-2 transmission (Table 2). The studies included in the reviews were primarily observational. In one review (Chen 2020), there was a higher risk of infection in close contacts and healthcare workers without PPE compared to the general population. A second review (Chu 2020) found a significant association between proximity of exposure (distance <1m), absence of barriers (not using face covering or eye protection) and the risk of infection. The authors of three reviews (Li 2020, Ludvigsson 2020, Zhu 2020) concluded that children were unlikely to be the main conduit for transmission of SARS-CoV-2, and results of one review (Koh 2020) showed that adults with close contact exposure were significantly more likely to be infected compared with children (14 studies, RR: 1.71 (95% CI: 1.35, 2.17)). In one review (Xu 2020), the attack rates were significantly less in students compared with staff ($p<0.01$). One review (Fung 2020) reported household SARs ranging from 3.9% to 36.4%, but also highlighted the lack of SARS-CoV-2 research in Africa, South Asia, and Latin America. One review (Madewell 2020) found that SARs were higher in households from symptomatic index cases than asymptomatic index cases, and one review (Yanes-Lane 2020) concluded that the proportion of asymptomatic infection was high (20–75%). In two reviews (Koh 2020, Yanes-Lane 2020), studies judged to be of low quality were excluded from their meta-analyses. In one review (Chen 2020), the overall quality was reported as low, while 80% of included studies were reported as moderate or high quality in another two (Fung 2020, Madewell 2020). Another review (Chu 2020) reported the overall risk of bias as low-to-moderate, and one (Xu 2020) rated the overall quality as low. Three reviews did not assess study quality (see Table 2).

Primary studies

We found 171 primary studies (Table 1). In general, the studies did not report any hypothesis but assessed epidemiological or mechanistic evidence for transmission associated with close contact settings. Ninety-three studies (54.4%) were conducted in Asia, 43 (25.1%) in Europe, 27 (15.8%) in North America, five (2.9%) in South America and three (1.8%) in Australasia. The

Table 1. Close contact study characteristics.

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Abdulrahman 2020	Bahrain	Observational comparative Country-wide 09/2020	Community	Before and after study of subjects attending 2 religious events	PCR	Not reported	No	>40 was considered negative	A 10-day period before the event was compared to a 10-day period beginning 10 days after the event. All symptomatic individuals and close contacts to a confirmed case were tested. Positive and negative controls were included for quality control purposes.
Adamik 2020	Poland	Observational Home	Household	9756 index cases; 3553 secondary cases	Not reported	Not reported	No	No	Only cases for which clear epidemiological links were registered as household transmission together with their source cases were included. Cases in social care units and households of minimum 15 inhabitants were removed from the analysis, as an initial analysis revealed that those were not representative for the overall population, due to over-represented comorbidities and severe cases.
Agergaard 2020	Denmark	Home quarantine with 1 asymptomatic index case 11/03/2020 to 01/04/2020	Household	Family cluster of 5: Index case arranged a self-imposed 2-week home quarantine along with family of four	PCR Serology	Not reported for PCR	No	Not specified for PCR	Index case recently returned from skiing trip in Austria iFlash SARS-CoV-2 N/S IgM/IgG cut-off: ≥12 AU/ml = positive. DiaSorin SARS-CoV-2 S1/S2 IgG cut-off: ≥15 AU/ml = positive
Angulo-Bazán 2020	Peru	Observational retrospective Household 23/04/2020 to 02/05/2020	Household	52 households in Metropolitan Lima with only one member with COVID-19 Contacts cohabited in same home with index case	RT-PCR (index) Serology	Not reported	No	Not specified	Evaluation was conducted 13.6 ± 3.7 days after the diagnostic test
Armann 2020	Germany	Observational - cross-sectional Schools, homes May to October 2020	Local Household	1538 students and 507 teachers were initially enrolled, and 1334 students and 445 teachers completed both study visits.	Serology	Week 0 and Week 16	No	N/A	an index (S/C) of < 1.4 was considered negative whereas one >/= 1.4 was considered positive) and an ELISA detecting IgG against the S1 domain of the SARS-CoV-2 spike protein (Euroimmun® Anti-SARS CoV-2 ELISA) (a ratio < 0.8 was considered negative, 0.8–1.1 equivocal, > 1.1 positive)
Arnedo-Pena 2020	Spain	Retrospective cohort Homes February-May 2020	Household	347 index cases: 745 household contacts	RT-PCR	Not reported	No	Not specified	COVID-19 cases of community outbreaks and from institutions as nursing homes were excluded. Secondary attack rate was defined as the proportion of secondary cases from the total of contacts that live in the household of index case.
Baker 2020	USA	Observational Acute-care hospital	Nosocomial	44 HCWs who provided care for a hospitalized patient with COVID-19 without PPE due to delayed diagnosis of COVID-19	RT-PCR	Not reported	No	Not specified	Contact and droplet precautions (including eye protection) were instituted
Baettig 2020	Switzerland	Retrospective case series Military canton March 2020	Local	1 index case; 55 contacts	RT-PCR Serology	PCR: Within 24 hrs of index case for symptomatic subjects Serology: 14 days post-exposure	No	Not reported	Positive cases were defined with two positive PCR testing for SARS-CoV-2 from nasopharyngeal swabs.
Bao 2020	China	Observational Entertainment venue January and February 2020	Community	Potentially exposed workers, customers and their family members potentially exposed to COVID-19 subject at a swimming pool	RT-PCR	Not reported	No	Not specified	Men and women exhibited different usage behaviour in that male bathers occupied the entire area, but mainly stayed at the lounge hall, while female bathers always went home after a bath. The temperature and humidity were significantly higher than what they would have been in an open air-conditioning environment.
Basso 2020	Norway	Observational study Hospital	Nosocomial	Quarantined HCWs exposed to COVID-19 patient	PCR Serology	Approximately 2 weeks after viral exposure; 3 weeks for serology	No	N/A S/CO ratio ≥1 is positive for antibody	The HCWs were quarantined for 2 weeks due to participation in aerosol-generating procedures (AGPs) with insufficient personal protective equipment (PPE), or close contact viral exposure (defined as ≤2 m for ≥15 min).
Bays 2020	USA	Observational study Community hospital and university medical centre February and March, 2020	Nosocomial	Two index patients and 421 exposed HCWs	RT-PCR	Not reported	No	Not specified	Exposed staff were identified by analyzing the EMR and conducting active case finding in combination with structured interviews.They wore neither surgical masks nor eye protection, and were risk stratified based on examination of the medical record and subsequent phone interviews as follows: high risk: nose or mouth exposed during intubation or bronchoscopy; moderate: nose or mouth exposed and for over 2 minutes; and low: nose or mouth exposed under 2 minutes. Ct was 25 for 1 index case - day 15
Bi 2020	China	Retrospective cohort Home or quarantine facility January-February 2020	Local Household Community	391 SARS-CoV-2 cases and 1286 close contacts	RT-PCR	RT-PCR	No	Not reporred	Close contacts were identified through contact tracing of a confirmed case and were defined as those who lived in the same apartment, shared a meal, travelled, or socially interacted with an index case 2 days before symptom onset. Casual contacts (eg, other clinic patients) and some close contacts (eg, nurses) who wore a mask during exposure were not included in this group.

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Blaisdell 2020	USA	Observational study 4 overnight camps June–August 2020	Community	Multilayered prevention and mitigation strategy 642 children and 380 staff members, aged 7–70 years	RT-PCR	4.1 to 9.1 days after camp arrival	No	Not specified	Hygiene measures: Precamp quarantine, pre- and postarrival testing and symptom screening, cohorting, and physical distancing between cohorts. In addition, camps required use of face coverings, enhanced hygiene measures, enhanced cleaning and disinfecting, maximal outdoor programming, and early and rapid identification of infection and isolation.
Böhmer 2020	Germany	Observational Workplace, home January-February 2020	Local Household	1 index case; 241 contacts	RT-PCR WGS	3–5 days post-exposure	No	Not reported	
Boscolo-Rizzo 2020	Italy	Cross-sectional Homes March to April 2020	Household	179 primary cases; 296 household contacts	RT-PCR	Unclear	No	Not reported	
Brown 2020	USA	Survey - cross-sectional Classroom February to March, 2020	Local	Students exposed to an index case (teacher)	Serology	2 weeks post-exposre to index case	No	Reciprocal titers of >400 considered positive Reciprocal titers of >100 but <400 considered indeterminate	
Burke 2020	USA	Observational prospective Homes February to March 2020	Household	10 primary cases; 445 close contacts	Not reported	Within 2 weeks of exposure to infected case	No	Not reported	19 (4%) of the 445 contacts were members of a patient's household, and five of these 19 contacts continued to have household exposure to the patient with confirmed COVID-19 during the patient's isolation period; 104 (23%) were community members who spent at least 10 minutes within 6 feet of a patient with confirmed disease; 100 (22%) were community members who were exposed** to a patient in a health care setting; and 222 (50%) were health care personnel
Canova 2020	Switzerland	Observational case series Primary care setting	Nosocomial	1 index case; 21 HCWs who interacted with index case without PPE	RT-PCR	7 days after the initial exposure	No	Not reporred	
Cariani 2020	Italy	Retrospective Hospital March to April 2020	Nosocomial	HCWs in close contact with SARS-CoV-2-positive cases (patients, co-workers, or relatives), or with symptoms of RTI	RT-PCR	Not reported	No	<40 considered positive	
Charlotte 2020	France	Retrospective Indoor choir rehearsal March 2020	Community	Nonventilated room; sitting less close to one another than usual, but at a distance of <1.82m	RT-PCR	Not reported	No	Not reported	
Chaw 2020	Brunei	Observational Various March 2020	Local Community	Primary cases: Presumably infected at religious event in Malaysia Secondary cases: Epidemiologic link to a primary case	RT-PCR	Not reported	No	Not reported	Household, workplace, social, and a local religious gathering. Initial cluster of SARS-CoV-2 cases arose from 19 persons who had attended the Tablighi Jama'at gathering in Malaysia, resulting in 52 locally transmitted cases.
Chen 2020	China	Aircraft 24 January 2020	Aircraft	Close contact to 2 passengers presenting with a fever and URTI symptoms	RT-PCR	Not reported	No	Not reported	The aircraft was equipped with air handling systems.
Chen 2020a	China	Retrospective observational Home or workplace January-March 2020	Local Household	69 recurrent-positive patients; 209 close contacts	RT-PCR	Every 3 days	No	Not specified	
Chen 2020b	China	Prospective cohort Hospital January-February 2020	Nosocomial	5 index patients; 105 HCWs	RT-PCR Serology	From 14 days post-exposure: 1st & 14th day of quarantine	No	<40 considered positive	
Chen 2020c	China	Observational Various January to March 2020	Local Household Community Nosocomial	157 locally reported confirmed cases, 30 asymptomatic infections; 2147 close contacts	Not reported	Unclear	No	Not reported	Family members, relatives, friends/pilgrims, colleagues/classmates, medical staff, and general personnel judged by the investigator.
Cheng 2020	Taiwan	Observational Homes, hospital January to March 2020	Household Nosocomial	100 confirmed cases of confirmed; 2761 close contacts	RT-PCR	Unclear	No	Not reported	
Chu 2020	USA	Observational Various January 2020	Community	Close contacts for an early confirmed case of COVID-19	RT-PCR Serology	Unclear	No	Antibody titers >400 considered seropositive.	Office, Community, Urgent care clinic identified via contact tracing
Chu 2020a	USA	Retrospective cohort study Household	Household	Household contacts of primary cases defined as children and adolescents with lab-confirmed COVID-19 (n=224)	Not reported	Not reported	No	Not reported	Did not distinguish between confirmed and probable cases among household contacts. A "primary case" is camp attendee with the earliest onset date in the household and a "secondary case" as a household contact with confirmed or probable COVID-19.

F1000Research 2021, 10:280 Last updated: 04 NOV 2022

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Contejean 2020	France	Observational Comparative Tertiary-care university hospital Feb-Mar 2020	Nosocomial	HCW exposed to COVID-19 patients	RT-PCR	Not reported	No	Not reported: result was +ve if 3/5 of gene targets amplified	Hygiene measures: All employees were encouraged to wear a face mask as often as possible in hospital (particularly in the presence of other persons), to wash/disinfect their hands regularly (and after every contact with other persons), to stay at least 2 meters away from others, to cover their mouth and nose with a tissue or sleeve when coughing or sneezing, to put used tissues in the bin immediately and wash hands afterwards, to avoid touching eyes, mouth. Educational messages were released on the internal website and on posters placed in all hospital premises.
COVID-19 National Emergency Response Center 2020	S. Korea	Observational Various January to March 2020	Local Household Nosocomial	30 cases; 2,370 contacts	RT-PCR	Not reported	No	Not reported	Homes, work, hospitals
Danis 2020	France	Observational case series Chalet, school January to February 2020	Local Household	I adult case with 15 contacts in chalet; 1 paediatric case with 172 school contacts	RT-PCR	Within 5 days of diagnosis of cases	No	Not reported	The index case stayed 4 days in the chalet with 10 English tourists and a family of 5 French residents. One pediatric case, with picornavirus and influenza A coinfection, visited 3 different schools while symptomatic.
Dattner 2020	Israel	Observational Home March to June 2020	Household	637 households, average household size of 5.3	RT-PCR Serology	Serology: 4 weeks post PCR testing	No	Not reported	
de Brito 2020	Brazil	Observational descriptive Household April-May 2020	Household	Socially distanced household contacts of index case	RT-PCR Serology	Serology: 4 weeks post-exposure PCR unclear	No	Not reported	Index case: First member of the cluster who had symptoms and who had a known risk of exposure outside the household during the family's stay in the same condominium; secondary case: Contacts with the index case. Asymptomatic patients: Those who had household contact and positive serology but no symptoms. Probable cases corresponded to confirmed case contacts who developed symptoms compatible with COVID despite negative serology and/or negative RT-PCR results.
Deng 2020	China	Observational Home January to February 2020	Household	27 cases; 347 close contacts	Not reported	Not reported	No	Not reported	
Desmet 2020	Belgium	Observational - cross-sectional School November 2019 to March 2020	Local	84 aged between 6 and 30 months attending daycare	RT-PCR	First weeks of the epidemic in Belgium	No	Not reported	
Dimcheff 2020	USA	Survey: cross-sectional Tertiary-care referral facility June 8 to July 8, 2020	Community Nosocomial Household	HCW exposed to COVID-19 patients either in or outside hospital	Serology	8 weeks post-exposure	No	Not reported	Hygiene measures: Daily COVID-19 symptom screening upon building entry, exclusion of visitors from the facility, and institution of telework in remote offices or at home, isolation of confirmed COVID-19 patients, conversion of COVID-19 wards to negative pressure environments, use of PAPRs) or N95 respirators along with PPE by staff.
Dong 2020	China	Observational Homes	Household	135 cases; 259 close contacts	Not reported	Not reported	No	Not reported	
Doung-ngern 2020	Thailand	Retrospective case-control Various March to April 2020	Local	3 large clusters in nightclubs, boxing stadiums, and a state enterprise office	RT-PCR	Not reported	No	Not reported	Hygiene measures: Consistent wearing of masks, handwashing, and social distancing in public.
Draper 2020	Australia	Observational Various March to April 2020	Local Household Nosocomial	28 cases; 445 close contacts	RT-PCR	Within 2 weeks of exposure to infected case	No	Not reported	Cruise ship, homes, aircraft, hospital
Dub 2020	Finland	Retrospective cohort (2) School and Household	Local Household	School and household contacts of 2 index cases who contracted COVID-19 at school	RT-PCR Serology	Serology: >4 weeks post-exposure	No	MNT titre of ≥ 6 considered positive FMIA titre 3·4 U/ml considered positive	
Expert Taskforce 2020	Japan	Observational prospective Cruise ship February 2020	Local	3,711 persons in cruise ship	RT-PCR	Not reported	No	Not reported	Passengers were allowed a 60-minute period on an exterior deck each day, during which they were instructed to wear masks, refrain from touching anything, and maintain a 1-meter distance from others. Monitors observed these periods. After each group came a 30-minute period in which the areas were disinfected. Room cleaning was suspended. Food and clean linens were delivered to cabin doors by crew, and dirty dishes and linens were picked up at cabin doors by crew. Only symptomatic close contacts were tested initially.
Fateh-Moghadam 2020	Italy	Observational Various March to April 2020	Community	2,812 cases; 6,690 community contacts	Not reported	Not reported	No	Not reported	Institutional settings including nursing homes, hospitals, day and residential centers for the disabled and similar structures, and convents

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Firestone 2020	USA	Observational retrospective Motorcycle rally August-September 2020	Local	51 primary event-associated cases, and 35 secondary or tertiary cases	RT-PCR WGS Phylogenetic analysis	Unclear	No	Not reported	**Secondary cases**: Laboratory-confirmed infections in persons who did not attend the rally but who received SARS-CoV-2–positive test results after having contact with a person who had a primary case during their infectious period. **Tertiary cases** were laboratory-confirmed cases in persons who had contact with a person who had a secondary case during their infectious period. SARS-CoV-2 RNA-positive clinical specimens were obtained from clinical laboratories, and
Fontanet 2020	France	Retrospective cohort study School March to April 2020	Local	661 participants: pupils, their parents and siblings, as well as teachers and non-teaching staff of a high-school	Serology	10 weeks	No	N/A	
Fontanet 2020a	France	Retrospective cohort study Schools April 2020	Local	510 participants: pupils, their parents and siblings, as well as teachers and non-teaching staff of a high-school	Serology	10 weeks	No	N/A	6 primary schools
Gan 2020	China	Observational retrospective survey Various January-February 2020	Local Household Community	1 052 cases in 366 epidemic clusters	Not reported	Not reported	No	Not reported	Family living together, gathering dinner, collective work, ride-thy-car, other aggregation exposure,
Ghinai 2020	USA	Observational 2 Social gatherings January-March 2020	Community	16 cases (7 confirmed and 9 probable) (1 index case)	RT-PCR	Not reported	No	Not reported	A birthday party, funeral, and church attendance.
Gong 2020	China	Observational Various January-February 2020	Household Community	3 clusters: 5 index cases; 9 close contacts	RT-PCR	Not reported	No	Not reported	Travelling and dining, or were living together
Gong 2020	China	Observational Karaoke room January 2020	Local	14 people exposed to 2 index cases in a karaoke room	RT-PCR Serology	PCR: Within 72 hrs post-exposure Serology: 6 weeks post-exposure	No	Not reported	
Hamner 2020	USA	Observational Choir practice March 2020	Local	1 index case; 60 close contacts	RT-PCR	Within 2 weeks of index case	No	Not reported	
Han 2020	S. Korea	Observational Spa facility Mar-April 2020	Community	Contacts for 10 index cases from Spa facility	RT-PCR	Not reported	No	Not reported	
Heavey 2020	Ireland	Observational School March 2020	Local	6 index cases; 1155 contacts	Not reported	Not reported	No	No	Three paediatric cases and three adult cases of COVID-19 with a history of school attendance were identified. Exposed at school in the classroom, during sports lessons, music lessons and during choir practice for a religious ceremony, which involved a number of schools mixing in a church environment.
Helsingen 2020	Norway	RCT Training facilities May-June 2020	Local	Members of the participating training facilities age 18 years or older who were not at increased risk for severe Covid-19	RT-PCR Serology	Serology: 4 weeks after start of study	No	Not reported	Hygiene measures: Avoidance of body contact; 1 metre distance between individuals at all times; 2 metre distance for high intensity activities; provision of disinfectants at all work stations; cleaning requirements of all equipment after use by participant; regular cleaning of facilities and access control by facility employees to ensure distance measures and avoid overcrowding. Changing rooms were open, but showers and saunas remained closed. All participants were mailed a home-test kit including two swabs and a tube with virus transport medium for SARS-CoV-2 RNA
Hendrix 2020	USA	Observational Hair salon May 2020	Local	Contacts for 2 stylists who tested positive for COVID-19	PCR	Not reported	No	Not reported	Hygiene measures: During all interactions with clients at salon A, stylist A wore a double-layered cotton face covering, and stylist B wore a double-layered cotton face covering or a surgical mask.
Hirschman 2020	USA	Observational study Home and social gatherings June 2020	Household Community	2 index cases; 58 primary and secondary contacts	RT-PCR	Unclear	No	Not reported	
Hobbs 2020	USA	Case-control study University Medical Centre September-November 2020	Local Household Community	397 children and adolescents: Cases 154; controls 243	RT-PCR	Not reported	No	Not reported	

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Hoehl 2020	Germany	Observational Daycare Centre 12 weeks (June-Sept 2020)	Local Community	Attendees and staff from 50 daycare centres	RT-PCR	Not reported	No	Not reported	Hygiene measures: Barring children and staff with symptoms of COVID-19, other than runny nose, from entering the facilities, as well as denying access to individuals with known exposure to SARS-CoV-2. Access to the facilities was also denied to children if a household member was symptomatic, or was in quarantine due to contact with SARS-CoV-2. Wearing of masks was not mandatory for children or nor staff. The access of caregivers to the facilities was limited.
Hong 2020	China	Observational prospective Home January-April 2020	Household	9 patients with recurrent infection; 13 close contacts	RT-PCR Serology NGS	After re-admission of index patients.	No	Not reported	
Hu 2020	China	Observational retrospective Various January to April 2020	Household Community	1178 cases; 15,648 contacts	Not reported	Not reported	No	Not reported	Homes, social events, travel, other settings
Hua 2020	China	Observational retrospective Home January to April 2020	Household	Children and adult contacts from the 314 families	RT-PCR	Not reported	No	Not reported	
Huang 2020	China	Prospective contact-tracing study Restaurant, home January 2020	Household Community	1 indes case; 22 close contacts	RT-PCR	Within 3 days of index cases	No	Not reported	Close contacts quarantined at home or hospital
Huang 2020a	Taiwan	Retrospective case series Various January-April 2020	Local Household Community Nosocomial	15 primary cases: 3795 close contacts	RT-PCR	Not reported	No	Not reported	Aircraft, home, classroom, workplace, hospital
Islam 2020	Bangladesh	Observational Various March to June 2020	Local Household Community Nosocomial	181 cases; 391 close contacts	Not reported	Not reported	No	Not reported	Household, health care facility, funeral ceremony, public transportation, family members, and others
Jia 2020	China	Observational Home January to February 2020	Household	11 clusters (n=583)	RT-PCR	Not reported	No	<37 considered positive	A **close contact** was defined as a person who did not take effective protection against a suspected or confirmed case 2 d before the onset of symptoms or an asymptomatic infected person 2 d before sampling. Ct-value of 40 or more was defined as negative.
Jiang 2020	China	Observational Home January to February 2020	Household Community	8 index cases, 300 contacts	rRT-PCR WGS Phylogenetic analysis	Every 24 hours for 2 weeks	No	<37 considered positive	Ct value ≥40 was considered negative. The maximum likelihood phylogenetic tree of the complete genomes was conducted by using RAxML software with 1000 bootstrap replicates, employing the general time-reversible nucleotide substitution mode
Jing 2020	China	Retrospective cohort study Homes January-February 2020	Household	195 unrelated close contact groups (215 primary cases, 134 secondary or tertiary cases, and 1964 uninfected close contacts)	RT-PCR	Days 1 and 14 of quarantine	No	Not reported	
Jing 2020a	China	Observational study Homes, public places February 2020	Household Community	68 clusters involving 217 cases	RT-PCR	Not reported	No	Not reported	
Jones 2020	UK France	Observational Super League Rugby August to October 2020	Local	136: 8 index cases: 28 identified close contacts and 100 other players	RT-PCR	Within 14 days of match day	No	Not specified: Ct for index cases 17.8 to 27	**Close contacts** were defined by analysis of video footage for player interactions and microtechnology (GPS) data for proximity analysis. All participants were within a ≤7-day RT-PCR screening cycle
Kang 2020	S. Korea	Observational Night clubs April-May 2020	Local	96 primary cases and 150 secondary cases; 5,517 visitors	Not reported	Not reported	No	Not reported	
Kant 2020	India	Retrospective (contact tracing) Regional Medical Research Centre May 2020	Local Community Nosocomial	1 index case diagnosed post-mortem; number of exposures unclear	RT-PCR	Unclear	No	Not reported	Contacts traced: People from the market where the index case had his shop, his treating physicians, people who attended his funeral, family members and friends
Kawasuji 2020	Japan	Case-control study University Hospital April-May 2020	Nosocomial	28 index cases: 105 close contacts	RT-PCR	Unclear	No	Not reported	Index patients and those with secondary transmission were estimated based on serial intervals in the family clusters.
Khanh 2020	Vietnam	Retrospective Aircraft March 2020	Community	1 index case: 217 close contacts	PCR	4 days after positive test result of index case	No	Not reported	Successfully traced passengers and crew members were interviewed by use of a standard questionnaire, tested for SARS-CoV-2
Kim 2020	S. Korea	Retrospective observational Home setting January-April 2020	Household	107 paediatric index cases: 248 household members of which 207 were exposed	RT-PCR	Within 2 days of COVID-19 diagnosis of the index case	No	Ct value of □35 is positive and >40 is negative	Guardian wore a KF94 (N95 equivalent) mask, gloves, full body suit (or waterproof long-sleeve gowns) and goggles.

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Kim 2020a	S. Korea	Case series Various January-February 2020	Household Community	1 index case; 4 close contacts	RT-PCR	4 days post-exposure	No	N/A	2 household contacts, 1 church contact, 1 restaurant
Kim 2020b	S. Korea	Retrospective observational University hospital February 2020	Nosocomial	4 confirmed cases: 290 contacts	RT-PCR	Within 8 days of index case diagnosis	No	Ct <35 was considered positive	Medical staff in the triage room used level-D PPE and everyone in the hospital was encouraged to wear masks and follow hand hygiene practices. Contact with confirmed COVID-19 cases was frequent among inpatients and medical support personnel.
Kumar 2020	India	Observational Community March-May 2020	Community	144 source cases:	RT-PCR	Unclear	No	Not reported	Persons with symptoms of ILI and SARI as well as known high-risk contacts of a confirmed COVID-19 patient were included.
Kuwelker 2020	Norway	Prospective case-ascertained study Homes Feb-April 2020	Household	112 index cases; 179 household members	Serology	6–8 weeks after symptom onset in the index case.	No	N/A	Single-person households were excluded from the analysis. Serum samples from index cases and household members were collected 6–8 weeks after symptom onset in the index case.
Kwok 2020	Hong Kong	Retrospective observational Quarantine or isolation February 2020	Local Household	53 cases; 206 close contacts	Not reported	Not reported	No	Not reported	A **secondary case** referred to the first generation of infection induced by an index case following contact with this case
Ladhani 2020	UK	Prospective Care homes April 2020	Nosocomial	6 London care homes reporting a suspected outbreak (2 or more cases); 254 staff members	RT-PCR	Not reported	No	Not reported	254 of 474 (54%) staff members provided a nasal self-swab; 12 were symptomatic at the time of swabbing
Ladhani 2020a	UK	Prospective Care homes April 2020	Nosocomial	6 London care homes reporting a suspected outbreak (2 or more cases); 254 staff members; 264 residents	RT-PCR	Not reported	Yes	Unclear: Ct values <35 were cultured	254 of 474 (54%) staff members provided a nasal self-swab; 12 were symptomatic at the time of swabbing
Laws 2020	USA	Prospective cohort Home setting March-May 2020	Household	1 pediatric index case: 188 household contacts	RT-PCR	Study enrollment (day 0); study close-out (day 14)	No	Not reported	Index case: household member with earliest symptom onset (and positive SARS-CoV-2 RT-PCR test result). Community prevalence in the 2 metropolitan areas was low during this time, and both were under stay-at-home orders. All enrolled index case patients and household contacts were followed prospectively for 14 days. Five households were selected for intensive swabbing requiring collection of respiratory specimens from all household members during four interim visits regardless of symptom presence.
Laxminarayan 2020	India	Observational Various April to August 2020	Local Household Community	3,084,885 known exposed contacts	Not reported	Not reported	No	Not reported	Individual-level epidemiological data on cases and contacts, as well as laboratory test results, were available from 575,071 tested contacts of 84,965 confirmed cases.
Lee 2020	S. Korea	Observational Hospital February-June 2020	Household	12 paediatric cases; 12 guardians as close contact. All guardians used PPE	Not reported	Not reported	No	Not reported	
Lee 2020a	S. Korea	Observational Homes February to March 2020	Household	23 close contacts	PCR	Unclear	No	Not reported	
Lewis 2020	USA	Observational Homes March to April 2020	Household	58 households (Utah, n = 34; Wisconsin, n = 24), 58 primary patients and 188 household contacts	RT-PCR Serology	Not reported	No	Not reported	
Li 2020	China	Observational Home setting Feb 2020	Household	Family cluster of 1 index case: 5 household contacts	RT-PCR	One day after index case tested positive	No	Not reported	Unknown when index case started shedding virus
Li 2020a	China	Observational case series Home, hospital January-February 2020	Household Nosocomial	2-family cluster of 1 index case: 7 close contacts	Not reported	Not reported	No	Not reported	
Li 2020b	China	Retrospective observational Home January-February 2020	Household	3-family cluster of 3 index cases: 14 close contacts	RT-PCR	Every 2–3 days until hospital discharge.	No	<38 considered positive	
Li 2020c	China	Retrospective observational Home January-March 2020	Household	30 cases from 35 cluster-onset families (COFs) and 41 cases from 16 solitary-onset families (SOFs)	Not reported	Not reported	No	Not reported	
Li 2020d	China	Observational Household February to March 2020	Household	105 index patients; 392 household contacts	RT-PCR	Within 2 weeks of exposure to infected case	No	Not reported	

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Liu 2020	China	Retrospective observational Home setting Feb 2020	Household	Family cluster of 1 index case: 7 household contacts	RT-PCR	Immediately after index case tested positive	No	If both the nCovORF1ab and nCoV-NP showed positive results, COVID-19 infection was considered	Unclear whether the index case was actually first case
Liu 2020a	China	Retrospective case series Hospital January 2020	Nosocomial	30 HCWs with direct contact with patients	RT-PCR	Not reported	No	<40 considered positive	30 cases have a history of direct contact with patients with neo-coronary pneumonia (within 1 m), 1 to 28 contacts, an average of 12 (7,16) contact times, contact time of 0.5 to 3.5 h, the average cumulative contact time of 2 (1.5, 2.7)h.
Liu 2020b	China	Retrospective cohort study Various January-March 2020	Household Community Nosocomial	1158 index cases: 11,580 contacts	RT-PCR	Every several days	No	Not reported	Homes, social venues, various types of transportations
Liu 2020c	China	Prospective observational	Unclear	147 asymptomatic carriers: 1150 close contacts	RT-PCR	Not reported	No	Not reported	RT-PCR for asymptomatic carriers - testing method not described for close contacts
López 2020	USA	Retrospective contact tracing School setting April-July 2020	Local Household	12 index pediatric cases: 101 facility contacts; 184 overall contacts	RT-PCR	Not reported	No	Not reported	Index case: first confirmed case identified in a person at the child care facility Primary case: Earliest confirmed case linked to the outbreak. Overall attack rates include facility-associated cases, nonfacility contact cases iand all facility staff members and attendees and nonfacility contacts
Lopez Bernal 2020	UK	Observational Homes January to March 2020	Household Community	233 households with two or more people; 472 contacts.	PCR	Unclear	No	Not reported	Healthcare workers, returning travellers and airplane exposures were excluded.
Lucey 2020	Ireland	Observational Hospital March-May 2020	Nosocomial	5 HCWs in cluster 1; 2 HCWs in cluster 3; HCW in cluster 2 not specified; 52 patients infected with SARS-CoV-2;	RT-PCR WGS Phylogenetic analysis	Not reported	No	Not reported	SARS-CoV-2 RNA was extracted from nasopharyngeal swabs obtained from COVID-19 cases and their corresponding HCWs were sequenced to completion. HA COVID-19 was classified into two groups according to the length of admission: >7 days and >14 days. The majority of patients required assistance with mobility (65%) and selfcare (77%)
Luo 2020	China	Observational retrospective Public transport January 2020	Community	1 index case; 243 close contacts	RT-PCR	Within 2 weeks of exposure to index case	No	Not reported	The tour coach was with 49 seats was fully occupied with all windows closed and the ventilation system on during the 2.5-hour trip.
Luo 2020a	China	Prospective cohort study Various January to March 2020	Household Community Nosocomial	391 index cases; 3410 close contacts	RT-PCR Serology	Every 24 hours.	No	Not reported	Homes, public transport; healthcare settings, entertainment venues, workplace, multiple settings
Lyngse 2020	Denmark	Retrospective Homes February to July 2020	Household	990 primary cases; 2226 household contacts	Not reported	Within 14 days of exposure to primary case	No	Not reported	Secondary cases: those who had a positive test within 14 days of the primary case being tested positive. 3 phases of epidemic examined. Assumed that the secondary household members were infected by the household primary case, although some of these secondary cases could represent co-primary cases. A longer cutoff time period could result in misclassification of cases among household members with somewhere else being the source of secondary infections.
Ma 2020	China	Observational Medical isolation	Unclear	1665 close contacts	RT-PCR	Not reported	No	Not reported	
Macartney 2020	Australia	Prospective cohort study Educational settings April to May 2020	Local	27 primary cases; 633 contacts	RT-PCR, serology, or both	PCR: 5–10 days after last case contact if not previously collected Serology: day 21 following last case contact.	No	Not reported	**Index case:** The first identified laboratory-confirmed case who attended the facility while infectious. A school or ECEC setting primary case was defined as the initial infectious case or cases in that setting, and might or might not have been the index case. **Primary case:** Initial infectious case or cases in that setting, and might or might not have been the index case **Secondary case:** Close contact with SARS-CoV-2 infection (detected through nucleic acid testing or serological testing, or both), which was considered likely to have occurred via transmission in that educational setting.
Malheiro 2020	Portugal	Retrospective cohort study Homes March to April 2020	Household	Intervention group (n=98), Control (n=453)	Not reported	Not reported	No	Not reported	The intervention group comprised all COVID-19 confirmed cases that were either identified as close contacts of an index caseor returned from affected areas and placed under mandatory quarantine, with daily follow-up until laboratory confirmation of SARS-CoV-2 infection. The control group included all COVID-19 confirmed cases that were not subject to contact tracing nor to quarantine measures preceding the diagnosis.

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Maltezou 2020	Greece	Retrospective observational Home setting February to June 2020	Household	203 SARS-CoV-2-infected children; number of index cases and close contacts unclear	RT-PCR	Not reported	No	Ct >38 considered negative	A **family cluster** was defined as the detection of at least 2 cases of SARS-CoV-2 infection within a family. First case was defined as the first COVID-19 case in a family. High, moderate, or low viral load (Ct <25, 25–30 or >30, respectively)
Maltezou 2020a	Greece	Retrospective observational Home setting February to May 2020	Household	23 family clusters of COVID-19; 109 household members	RT-PCR	Not reported	No	<25, 25–30 or >30	A **family cluster** was defined as the detection of at least 2 cases of SARS-CoV-2 infection within a family. Index case was defined as the first laboratory-diagnosed case in the family.
Mao 2020	China	Cross-sectional study Home, family gatherings January-March 2020	Household Local	67 clusters with 226 cases confirmed cases	RT-PCR	Not reported	No	Not reported	
Martinez-Fierro 2020	Mexico	Cross-sectional June-July 2020	Unclear	19 asymptomatic index cases; 81 contacts	RT-PCR Serology	Not reported	No	Not reported	
Mponponsuo 2020	Canada	Observational Hospital March-April 2020	Nosocomial	5 HCWs were index cases; 39 HCWs (16 underwent testing) and 33 patients were exposed (22 underwent testing)	RT-PCR	Not reported	No	Not reported	All 5 HCWs had E gene cycle threshold (Ct) values between 10.9 and 30.2. Those exposed to the index HCWs were followed for 30 days
Ng 2020	Singapore	Retrospective cohort study Various January-April 2020	Household Local Community	1114 PCR-confirmed COVID-19 index cases in the community in Singapore. 13 026 close contacts (1863 household, 2319 work, and 3588 social)	RT-PCR Serology	If contacts reported symptoms	No	Not reported	**Lower risk contacts:** Other contacts who were with the index case for 10–30 min within 2 m Contacts who reported symptoms were admitted to the hospital for COVID-19 testing by PCR.
Ning 2020	China	Observational study Various January-February 2020	Household Local Community	Local cases: 3,435 close contacts Imported cases: 3,666 close contacts	Not reported	Not reported	No	Not reported	Imported cases, farmers' markets, malls and wildlife exposure
Njuguna 2020	USA	Observational Prison May 2020	Local	98 incarcerated and detained persons	RT-PCR	Not reported	No	Not reported	Unclear how many index or close contacts
Ogawa 2020	Japan	Observational Hospital	Nosocomial	1 index patient; 15 HCWs were contact	RT-PCR Serology	RT-PCR: 10th day after exposure Serology: Before isolation	No	Not specified	Viral culture performed for only the index patient
Paireau 2020	France	Retrospective observational Various January to March 2020	Household Local Nosocomial	735 index cases; 6,082 contacts	RT-PCR	Not reported	No	Not reported	Family, home, work, hospital. Index case: A case whose detection initiated an investigation of its contacts through contact tracing Only contacts who developed symptoms compatible with COVID-19 were tested for SARS-CoV-2
Park 2020	S. Korea	Retrospective observational Various February 2020	Local Household Community	2 index cases; 328 contacts	RT-PCR	24 hrs for 37 first contacts; others within 2 weeks	No	<40 considered positive	Aircraft, home, restaurant, clinic, pharmacy. Contact tracing of COVID-19 cases was conducted from 1 day before symptom onset or 1 day before the case was sampled.
Park 2020a	S. Korea	Observational study Homes January to March 2020	Household Non-household	5,706 COVID-19 index patients; 59,073 contacts	Not reported	Not reported	No	Not reported	
Park 2020b	S. Korea	Observational study Workplace, home March 2020	Local Household	216 employees, 225 household contacts	RT-PCR	Within 2 weeks of report of infected case	No	Not reported	Employees do not generally go between floors, and they do not have an in-house restaurant for meals. Sent a total of 16,628 text messages to persons who stayed >5 minutes near the building X; we tracked these persons by using cell phone location data.
Passarelli 2020	Brazil	Observational Hospital August 2020	Nosocomial	6 index cases; 6 close contacts	RT-PCR	Not reported	No	<40 considered positive	All index cases were asymptomatic hospital visitors
Patel 2020	UK	Retrospective observational Hospital, community March to April 2020	Household	107 cases; 195 household contacts	RT-PCR	Not tested	No	Not reported	
Pavli 2020	Greece	Observational contact tracing Aircraft February to March 2020	Aircraft	6 index cases; 891 contacts	RT-PCR	Not reported	No	Not reported	A COVID-19 case was defined at that time as a case with signs and symptoms compatible with COVID-19 in a patient with laboratory-confirmed SARS-CoV-2 infection, recent travel history to a country with evidence of local transmission of SARS-CoV-2 or close contact with a laboratory-confirmed case
Phiriyasart 2020	Thailand	Observational Homes April 2020	Household	471 household contacts	RT-PCR	Within 5 days of exposure	No	Not reported	
Poletti 2020	Italy	Observational February-April 2020	Unclear	5,484 close contacts from clusters	RT-PCR Serology	Not reported	No	Not reported	Only contacts belonging to clusters (i.e. groups of contacts identified by one positive index case) were included. 1,364 (25%) were tested with only RT-PCR, 3,493 (64%) with only serology at least a month after the reporting date of their index case and 627 (11%) were tested both by RT-PCR and serology.

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Pung 2020	Singapore	Observational Various February 2020	Local Community	425 close contacts from 3 clusters; index case unclear	PCR WGS Phylogenetic analysis	Not reported	No	Not reported	Company conference, church, tour group. Close contacts under quarantine for 14 days from last exposure to the individual with confirmed COVID-19, either at home or at designated government quarantine facilities.
Pung 2020a	Singapore	Observational Homes Up till March 2020	Household	277 were primary or co-primary cases: 875 household contacts	Not reported	Not reported	No	Not reported	Household contacts were tested if they showed symptoms of SARS-CoV-2 infection, or if aged 12 years or below
Qian 2020	Hong Kong	Observational retrospective Various January to February 2020	Local Household Community	Unclear	Not reported	Not reported	No	Not reported	Homes, transport, restaurants, shopping and entertainment venues. Four categories of infected individuals were considered based on their relationship: family members, family relatives, socially connected individuals, and socially non-connected individuals
Ravindran 2020	Indonesia	Retrospective cohort Wedding March 2020	Local	41 guests; no. of index cases unclear	RT-PCR	Not reported	No	Not reported	**Primary case:** Any person who attended the wedding events in Bali Indonesia during 15–21 March 2020 and who tested positive. **Secondary case:** any person who tested positive on SARS-CoV-2 after the 14 day period and who was a close contact of a COVID-19 case from the wedding events.
Razvi 2020	UK	Observational study Hospital May to June 2020	Nosocomial	2,521 HCWs	Serology	Voluntary first-come, first-served basis	No	N/A	
Rosenberg 2020	USA	Observational retrospective Homes March 2020	Household	229 cases; 498 household contacts	RT-PCR	Not reported	No	Not reported	
Roxby 2020	USA	Observational - cross-sectional Nursing home March 2020	Nosocomial	80 residents and 62 staff members; no index case	RT-PCR	Day 1 and 7 days late	No	No	Residents isolated in their rooms; no communal meals or activities, no visitors allowed in the facility, staff member screening and exclusion of symptomatic staff members implemented. Enhanced hygiene practices were put into effect, including cleaning and disinfection of frequently touched surfaces and additional hand hygiene stations in hallways for workers to use. All residents were tested again 7 days later.
Sang 2020	China	Case series Home February 2020	Household	1 index case; 6 family members	Not reported	Within 24 hrs of index case	No	Not reported	Central air conditioner was always running at home
Schumacher 2020	Qatar	Prospective cohort study Football team June to September 2020	Local	1337; no index cases	RT-PCR Serology	RT-PCR: Every 3–5 days Serology: Every 4 weeks	No	≤30 positive	Strict hygiene measures and regular testing. **Two phases**, the quarantine phase (entry until exit) and the training and match phase (after quarantine exit until the first test done during the week after the last match. Ct >30 but <40 reactive. 1337 subjects were tested at least once; however, some players and staff joined their team and were gradually included in (or left) the programme during the study period.
Schwierzeck 2020	Germany	Observational Hospital paediatric dialysis unit	Nosocomial	1 index case; 48 contacts	RT-PCR	24 hrs after index case	No	Not specified	**Outbreak** was defined as two or more COVID-19 infections resulting from a common exposure
Shah 2020	India	Observational Homes March to July 2020	Household	74 primary cases; 386 household contacts	RT-PCR	Not reported	No	Not reported	
Shen 2020	USA	Observational Social gathering January to February 2020	Household Community	1 index case: 539 social and family contacts	RT-PCR	If contact had symptoms	No	Not specified	
Sikkema 2020	Netherlands	Cross-sectional Hospital March 2020	Nosocomial	1796 HCWs; index case not specified	RT-PCR WGS Phylogenetic analysis	N/A	No	<32 considered positive	HCWs across 3 hospitals.
Son 2020	S. Korea	Observational study Homes January to March 2020	Household	108 primary cases; 3223 contacts	RT-PCR	Unclear	No	Not reported	
Song 2020	China	Observational case series Home January 2020	Household	4 family clusters. 4 index cases: 18 close contacts	RT-PCR	0 to 72 hrs after index case tested positive	No	Not reported	

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Speake 2020	Australia	Observational retrospective Aircraft March 2020	Aircraft	241 passengers some of whom had disembarked from 1 of 3 cruise ships that had recently docked in Sydney Harbour. 6 primary cases initially	RT-PCR WGS Phylogenetic analysis	Within 2 weeks of primary cases	Yes	Not specified	**Primary cases** as passengers with SARS-CoV-2 who had been on a cruise ship with a known outbreak in the 14 days before illness onset and whose specimen yielded a virus genomic sequence closely matching that of the ship's outbreak strain **Secondary cases: P**assengers with PCR-confirmed SARS-CoV-2 infection who had not been on a cruise ship with a known SARS-CoV-2 outbreak within 14 days of illness onset and in whom symptoms developed >48 hours after and within 14 days of the flight; or international passengers who had not been on a cruise ship in the 14 days before illness and whose specimens yielded a WGS lineage not known to be in circulation at their place of origin but that closely matched the lineage of a primary case on the flight.
Stein-Zamir 2020	Israel	Observational - cross-sectional Schools May 2020	Local	1,190 students aged 12–18 years (grades 7–12) and 162 staff members.	PCR	Unclear	No	Not reported	
Sugano 2020	Japan	Observational retrospective Music concerts February 2020	Local	1 index case; 72 exposures	RT-PCR	Not reported	No	Not specified	
Sun 2020	China	Observational Homes	Household	Family clusters	Not reported	Not reported	No	Not reported	
Taylor 2020	USA	Observational Skilled nursing facilities April-June 2020	Nosocomial	259 tested residents, and 341 tested HCP	RT-PCR WGS Phylogenetic analysis	Weekly serial testing (every 7–10 days)	No	Not specified	
Teherani 2020	USA	Observational Homes March to June 2020	Household	32 paediatric cases; 144 household contacts	PCR	Within 2 weeks of exposure to infected case	No	Not reported	Only children who presented with symptoms concerning for COVID-19 infection were included.
Thangaraj 2020	India	Observational Tourist group February 2020	Community	1 index case; 26 close contacts	RT-PCR	Within 24 hrs of index case	No	Not reported	
Torres 2020	Chile	Cross-sectional Community March-May 2020	Community	1009 students and 235 staff	Serology	8–10 weeks after school outbreak	No	N/A	The school was closed on March 13, and the entire community was placed in quarantine
Tshokey 2020	Bhutan	Observational Tourists May 2020	Local Community	27 index cases; 75 high-risk contacts, 1095 primary contacts; 448 secondary contacts	RT-PCR	High-risk contacts: minimum of three times with RT-PCR	No	≤ 40 considered positive	
van der Hoek 2020	Netherlands	Observational Household March to April 2020	Household	231 cases; 709 close contacts. 54 families have 239 participants, 185 of whom are family members.	RT-PCR Serology	Not reported	No	Not reported	
Wang 2020	China	Observational Home January-February 2020	Nosocomial Household	25 HCWs, 43 family members	RT-PCR WGS Phylogenetic analysis	Not reported	No	Not reported	
Wang 2020a	China	Retrospective observational Home February 2020	Household	85 primary cases: 155 household contacts in 78 households	RT-PCR	Not reported	No	<37 considered positive	
Wang 2020b	China	Retrospective cohort study Homes February to March 2020	Household	124 primary cases; 335 close contacts	RT-PCR	Within 2 weeks of symptom onset of the primary case	No	Not reported	
Wee 2020	Singapore	Observational Tertiary Hospital February to May 2020	Nosocomial	28 index cases; 253 staff close-contacts and 45 patient close-contacts	RT-PCR	If patient close-contacts or staff close-contacts developed symptoms	No	Not specified	Infection control bundle was implemented comprising infrastructural enhancements, improved PPE, and social distancing between patients. Patients were advised to wear surgical masks, to remain within their room or cohorted cubicle at all times, and to avoid mingling with each other.
Wendt 2020	Germany	Observational Hospital March 2020	Nosocomial	1 index case physician; 187 contacts with HCWs and 67 contacts with patients - 23 high-risk contacts in total	RT-PCR Serology	5-days post exposure (5 & 10 days post exposre for high-risk contacts	No	<36 or <39 considered positive	All high-risk contacts and the index physician were examined serologically on days 15 or 16 and days 22 or 23 after exposure.
Wolf 2020	Germany	Observational case series Hospital quarantine January-February 2020	Household	Family cluster: 1 index case, 4 close contacts	RT-PCR	5-days after index case tested positive	No	Not reported	The parents were asked to wear masks; wearing masks was not practical for the children.
Wong 2020	Hong Kong	Observational Hospital February 2020	Nosocomial	1 index case in AIIR: 71 staff and 49 patients	RT-PCR	End of 28-day surveillance	No	Not specified	

Study ID	Country	Study Design/Setting	Type of transmission	Population/environment	Test method	Timing of sample collection	Viral culture	Cycle threshold	Other information
Wood 2020	UK	Retrospective cohort HCW homes	Household	241,266 adults did not share a household with young children; 41,198, 23,783 and 3,850 shared a household with 1, 2 and 3 or more young children	PCR	Not reported	No	Not reported	Primary exposure was the number of children aged 0 to 11 years in each household.
Wu 2020	China	Retrospective cohort study Various January-February 2020	Household Local Community	144 cases, 2994 close contacts	Not reported	Not reported	No	Not reported	Shared transport, visit, medical care, household, brief contact.
Wu 2020a	China	Prospective observational Homes February to March 2020	Household	35 index cases; 148 household contacts	Not reported	Not reported	No	Not reported	All consecutive patients with probable or confirmed COVID-19 admitted to the Fifth Affiliated Hospital of Sun Yat-sen University from 17 January to 29 February 2020 were enrolled. All included patients and their household members were interviewed
Xie 2020	China	Cross-sectional Home January-February 2020	Household	2 family clusters with 61 residents (5 cases)	RT-PCR	7 days after primary or index cases diagnosed	No	Not reported	
Xin 2020	China	Prospective cohort study Homes January to March 2020	Household	31 primary cases; 106 household contacts	RT-PCR	Not reported	No	Not reported	
Yang 2020	China	Observational cohort study Home quarantine February-May 2020	Household Local	93 recurrent-positive patients; 96 close contacts and 1,200 candidate contacts	RT-PCR Serology	Within 14 days post-exposure	Yes	≤ 40 considered positive	
Yau 2020	Canada	Retrospective cohort study Hospital dialysis unit April 2020	Nosocomial	2 index cases; 330 contacts (237 patients and 93 staff)	RT-PCR	Not reported	No	Not reported	All symptomatic contacts were referred for testing but asymptomatic household contacts were not routinely tested as per public health protocols at the time.
Ye 2020	China	Observational Religious gathering January-February 2020	Local Community	66 confirmed cases and 15 asymptomatic infections: 1,293 close contacts	RT-PCR	Not reported	No	Not reported	All close contacts were quarantined
Yoon 2020	S. Korea	Observational Childcare Centre February-March 2020	Local	1 index case: 190 persons (154 children and 36 adults) were identified as contacts; 44 were defined as close contacts (37 children and 7 adults)	PCR	8–9 days after the last exposure	No	<37 considered positive	Wearing masks, more frequent hand hygiene, and disinfection of the environment were required before the child index case tested positive.
Yousaf 2020	USA	Survey: cross-sectional Tertiary-care referral facility June 8 to July 8, 2020	Household	198 household contacts; index cases not specified	RT-PCR	Day 1 of study	No	Not reported	
Yu 2020	China	Observational study Homes January to February 2020	Household	560 index cases; 1587 close contacts	Not reported	Within 2 weeks of exposure to primary case	No	Not reported	Exposure environments included workplace, medical centre, etc. Contact methods included eating or living together, sleeping together, living in same house, etc
Yung 2020	Singapore	Observational prospective Homes March to April 2020	Household	137 households, 213 paediatric contacts	Not reported	Unclear	No	Not reported	
Zhang 2020	China	Retrospective Observational Aircraft March-April 2020	Aircraft	4462 passengers screened for COVID-19 based on close contact	RT-PCR	Not reported	No	Not reported	All passengers were quarantined after arrival
Zhang 2020a	China	Retrospective observational Various January-March 2020	Household Local Community	359 cases: 369 close contacts	Not reported	Not reported	No	Not reported	Households, social contact, workplace
Zhang 2020b	China	Observational study Hospital April 2020	Household	3 index cases; 10 close contacts	RT-PCR Serology	Not reported	No	<37 considered positive	Ct value of 40 or more was defined as a negative test.
Zhang 2020c	China	Observational Quarantine January-February 2020	Local Household	Multi-family cluster of 22 cases: 93 close contacts	RT-PCR	Not specified	No	Not reported	All close contacts were quarantined in centralized facilities.
Zhang 2020d	China	Observational Supermarket January-February 2020	Local	1 index case: 8437 contacts	RT-PCR	Not reported	No	Not reported	
Zhuang 2020	China	Observational study Various January to February 2020	Household Community	Cluster outbreaks; 8363 close contacts	Not reported	Not reported	No	Not reported	Family and non-family cases

Table 2. Main characteristics of systematic reviews.

Study ID (n=9)	Fulfils systematic review methods	Research question (search date up to)	No. of included studies (No. of participants)	Main results	Key conclusions
Chen 2020	Yes	To estimate seroprevalence by different types of exposures, within each WHO region, we categorized all study participants into five groups: 1) close contacts, 2) high-risk healthcare workers, 3) low-risk healthcare workers, 4) general populations, and 5) poorly-defined populations **(Search from Dec 1, 2019 to Sep 25, 2020).**	230 studies involving 1,445,028 participants were included in our meta-analysis after full-text scrutiny: Close contacts 16 studies 2901 positives out of 9,349 participants	Estimated seroprevalence of all infections, 22.9% [95% CI, 11.1–34.7] compared to relatively low prevalence of SARS-CoV-2 specific antibodies among general populations, 6,5% (5.8–7.2%) see Appendix table 15 (page 152). The overall risk of bias was low.	There were a very limited number of high-quality studies of exposed populations, especially for healthcare workers and close contacts, and studies to address this knowledge gap are needed. Pooled estimates of SARS-CoV-2 seroprevalence based on currently available data demonstrate a higher infection risk among close contacts and healthcare workers lacking PPE,
Chu 2020	Yes	To investigate the effects of physical distance, face masks, and eye protection on virus transmission in health-care and non-health-care (eg, community) settings **(We searched up to March 26, 2020)**	Identified 172 studies; 44 studies included in the meta-analysis which 7 were Covid-19	A strong association was found of proximity of the exposed individual with the risk of infection (unadjusted n=10 736, RR 0·30, 95% CI 0·20 to 0·44; adjusted n=7782, aOR 0·18, 95% CI 0·09 to 0·38; absolute risk [AR] 12·8% with shorter distance vs 2·6% with further distance, risk difference. There were six studies on COVID-19, the association was seen irrespective of causative virus (p value for interaction=0·49). The risk of bias was generally low-to-moderate.	Physical distancing of at least 1 m is strongly associated with protection, but distances of up to 2 m might be more effective.
Fung 2020	Yes	To review and analyze available studies of the household SARs for SARS-CoV-2. Searched PubMed, bioRxiv, and medRxiv on **2 September 2020** for published and prepublished studies reporting empirical estimates of household SARs for SARS-CoV-2. Considered only English-language records posted on or after 1 January 2019. **Inclusion criteria:** Reported estimates of the household SAR or the data required to compute the household SAR; (2) comprised data from more than 1 household; and (3) they tested—at a minimum—all symptomatic household contacts by reverse transcription polymerase chain reaction (RT-PCR).	22 papers met the eligibility criteria: 6 papers reported results of prospective studies and 16 reported retrospective studies. The number of household contacts evaluated per study ranged from 11 to 10592.	The 22 studies considered 20 291 household contacts, 3151 (15.5%) of whom tested positive for SARS-CoV-2. Household secondary attack rate estimates ranged from 3.9% in the Northern Territory, Australia to 36.4% in Shandong, China. The overall pooled random-effects estimate of SAR was 17.1% (95% confidence interval [CI], 13.7–21.2%), with significant heterogeneity (p<0.0001). The household secondary attack rates was highest for index cases aged 10–19 years (18.6%; 95% CI, 14.0–24.0%) and lowest for those younger than 9 (5.3%; 95% CI, 1.3–13.7%). 4 of the studies were judges as high quality; 14 as moderate quality; and 4 as low quality. Between-study variation could not be explained by differences in study quality.	Secondary attack rates reported using a single follow-up test may be underestimated, and testing household contacts of COVID-19 cases on multiple occasions may increase the yield for identifying secondary cases. There is a critical need for studies in Africa, South Asia and Latin America to investigate whether there are setting-specific differences that influence the household SAR.
Koh 2020	Yes	The secondary attack rate (SAR) in household and healthcare settings. **Search between Jan 1 and July 25, 2020.**	118 studies, 57 were included in the meta-analyses.	Pooled household SAR 18.1% (95% CI: 15.7%, 20.6%) significant heterogeneity (p <0.001). No significant difference in secondary attack rates in terms of the definition of household close contacts, whether based on living in the same household (18.2%; 95% CI: 15.3%, 21.2%) or on relationships such as family and close relatives (17.8%; 95% CI: 13.8%, 21.8%) In three studies, the household secondary attack rates of symptomatic index cases (20.0%; 95% CI: 11.4%, 28.6%) was higher than asymptomatic ones (4.7%; 95% CI: 1.1%, 8.3%) SAR from 14 studies showed close contacts adults were more likely to be infected compared to children (<18), relative risk 1.71 (95% CI: 1.35, 2.17). 43 high-quality studies were included for meta-analysis.	There was variation in the definition of household contacts; most included only those who resided with the index case, some studies expanded this to include others who spent at least a night in the same residence or a specified duration of at least 24 hours of living together, while others included family members or close relatives.
Li_2020	No (quality assesment not performed)	~Carriage and transmission potential of SARS-CoV-2 in children in school and community settings **(Search performed on 21 June 2020 with entry date** **limits from late 2019)**	33 studies were included for this review. Four new studies on SARS-CoV-2 transmission in school settings were identified.	There is a lack of direct evidence on the dynamics of child transmission, however the evidence to date suggests that children are unlikely to be major transmitters of SARS-CoV-2.	The balance of evidence suggests that children play only a limited role in overall transmission, but it is noted that the relative contribution of children to SARS-CoV-2 transmission may change with reopening of society and schools
Ludvigsson 2020	No (quality assesment not performed)	Are children the main drivers of the COVID-19 pandemic **(Search to 11 May 2020)**	47 full texts studied in detail.	This review showed that children constituted a small fraction of individuals with COVID-19	Children are unlikely to be the main drivers of the pandemic. Data on viral loads were scarce, but indicated that children may have lower levels than adults,

F1000Research 2021, 10:280 Last updated: 04 NOV 2022

Study ID (n=9)	Fulfils systematic review methods	Research question (search date up to)	No. of included studies (No. of participants)	Main results	Key conclusions
Madewell 2020	Yes	What is the household secondary attack rate for severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)? (**Searched through Oct 19, 2020)** single database assessed	54 studies with 77,758 participants	Household secondary attack rates was 16.6%; restricted index cases to children (<18 years), lower SAR of 0.5% Secondary attack rates for household and family contacts 3 times higher than for close contacts (4.8%; 95% CI, 3.4%-6.5%; P < .001); Estimated mean household secondary attack rates from symptomatic index cases (18.0%; 95% CI, 14.2%-22.1%) higher than from asymptomatic or presymptomatic index cases (0.7%; 95% CI, 0%-4.9%; P < .001), there were few studies in the latter group. Infection risk was highest for spouses, followed by nonspouse family members and other relatives, all higher than other contacts. Estimated mean household secondary attack rates to spouses (37.8%; 95% CI, 25.8%-50.5%) higher than to other contacts (17.8%; 95% CI, 11.7%-24.8%). Significant heterogeneity was found among studies of spouses (I2 = 78.6%; P < .001) and other relationships (I2 = 83.5%; P < .001). Contact frequency with index case associated with higher odds of infection, At least 5 contacts during 2 days before the index case was confirmed; at least 4 contacts and 1 to 3 contacts, or frequent contact within 1 meter. Secondary attack rates for households with 1 contact (41.5%; 95% CI, 31.7%-51.7%) higher than households with at least 3 contacts (22.8%; 95% CI, 13.6%-33.5%; P < .001) but not different than households with 2 contacts (38.6%; 95% CI, 17.9%-61.6%). There was significant heterogeneity in secondary attack rates between studies with 1 contact (I2 = 52.9%; P = .049), 2 contacts (I2 = 93.6%; P < .001), or 3 or more contacts (I2 = 91.6%; P < .001). Information was not available on household crowding. A total of 16 of 54 studies (29.6%) were at high risk of bias, 27 (50.0%) were moderate, and 11 (20.4%) were low.	Secondary attack rates were higher in households from symptomatic index cases than asymptomatic index cases, to adult contacts than to child contacts, to spouses than to other family contacts, and in households with 1 contact than households with 3 or more contacts. Our study had several limitations. The most notable is the large amount of unexplained heterogeneity across studies. This is likely attributable to variability in study definitions of index cases and household contacts, frequency and type of testing, sociodemographic factors, household characteristics (eg, density, air ventilation), and local policies (eg, centralized isolation). The findings of this study suggest that households are and will continue to be important venues for transmission, even where community transmission is reduced.
Xu 2020	Yes	Evidence for transmission of COVID-19 by children in schools (**search in MEDLINE up to 14 September 2020.** Further hand-searched reference lists of the retrieved eligible publications to identify additional relevant studies). Included children (defined as ≤18 years old) who were attending school, and their close contacts (family and household members, teachers, school support staff) during the COVID-19 pandemic	11 studies were included: 5 cohort studies and 6 cross-sectional studies.	Overall infection attack rate (IAR) in cohort studies: 0.08%, 95% CI 0.00%-0.86%. IARs for students and school staff were 0.15% (95% CI 0.00%-0.93%) and 0.70% (95% CI = 0.00%-3.56%) respectively (p<0.01). Six cross-sectional studies reported 639 SARS-CoV-2 positive cases in 6682 study participants tested [overall SARS-CoV-2 positivity rate: 8.00% (95% CI = 2.17%-16.95%). SARS-CoV-2 positivity rate was estimated to be 8.74% (95% CI = 2.34%-18.53%) among students, compared to 13.68% (95% CI = 1.68%-33.89%) among school staff (p<0.01). Overall study quality was judged to be poor with risk of performance and attrition bias	There is limited high-quality evidence to quantify the extent of SARS-CoV-2 transmission in schools or to compare it to community transmission. Emerging evidence suggests lower IAR and SARS-CoV-2 positivity rate in students compared to school staff.
Yanes-Lane 2020	Yes	Proportion of asymptomatic infection among coronavirus disease 2019 (COVID-19) positive persons and their transmission potential. **(Search up to up to 22 June 2020)**	28 moderate/high quality studies included; 43 low quality studies excluded	Asymptomatic COVID-19 infection at time of testing ranged from 20% - 75%; among three studies in contacts it was 8.2% to 50%. Asymptomatic infection in obstetric patients pooled proprtion was 95% (95% CI, 45% to 100%) of which 59% (49% to 68%) remained asymptomatic through follow-up; Among nursing home residents, the proportion of asymtomoatic was 54% (42% to 65%) of which 28% (13% to 50%) remained asymptomatic through follow-up.	The proportion of asymptomatic infection among COVID-19 positive persons appears high and transmission potential seems substantial.
Zhu 2020	Meta-analysis: Quality assessment not performed	Role of children in SARS-CoV-2 in household transmission clusters (**Search between Dec, 2019 & Aug, 2020).**	57 articles with 213 clusters	8 (3.8%) transmission clusters were identified as having a paediatric index case. Asymptomatic index cases were associated with lower secondary attack rates in contacts than symptomatic index cases [RR] 0.17 (95% CI,0.09–0.29). SAR in paediatric household contacts was lower than in adult household contacts (RR, 0.62; 95% CI, 0.42–0.91).	The data suggest that should children become infected at school during this period, they are unlikely to spread SARS-CoV-2 to their co-habiting family members.

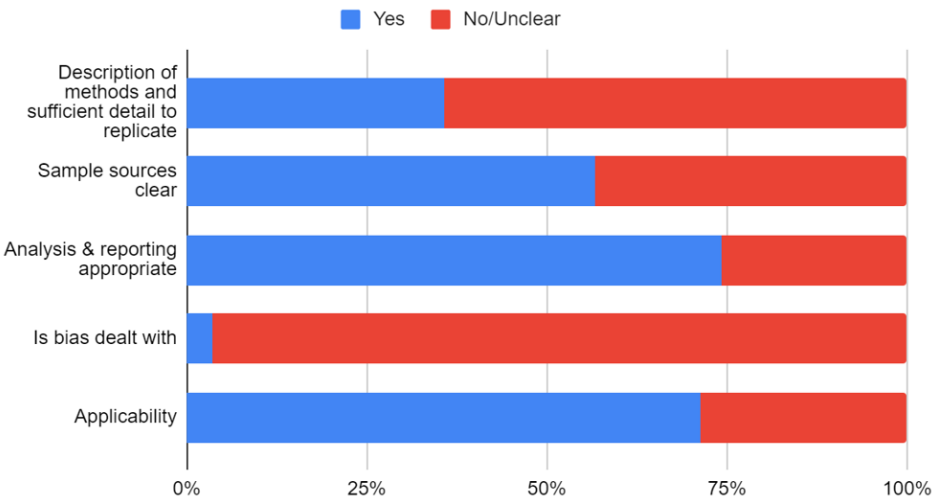

Figure 2. Risk of bias graph in primary studies of close contacts in SARS-CoV-2.

study settings included home/quarantine facilities (n=54), hospital (n=26), social/religious gatherings (n=13), public transport (n=7) care homes (n=4), and educational settings (n=8). Thirteen studies used two settings (home plus one other setting). In 25 studies (15.2%), the settings were multiple (3 or more different settings). Two studies were conducted in professional sports settings: one Super League Rugby (Jones 2020) and one football team (Schumacher 2020)

All the included studies were observational in design except one RCT (Helsingen 2020): 24 studies were described as cohort, nine were case series and 12 cross-sectional. One study used a before and after study design. The number of close contact participants included ranged from 4 to 8437. Three studies (Chen 2020a, Hong 2020, Yang 2020) examined transmission dynamics in close contacts of index or primary cases with recurrent SARS-CoV-2 infections.

Eighty-two studies (46.8%) reported definitions of close contacts (Table 3). There was a variation in the definitions across the studies. Seventeen studies (9.9%) defined close contact as exposure to the index or primary case within two metres for at least 15 minutes while four defined it as being within 2m for at least 10 minutes. In 24 studies, there was no specified distance reported - close contact definitions included unprotected exposure, living in the same household or bedroom, sharing a meal, or having repeated and prolonged contact. In five studies of airline passengers, close contact was defined as all passengers on the flight (Chen 2020), seated within two rows of the index case (Draper 2020, Pavli 2020, Speake 2020), or being within 2m for at least 15 minutes (Khanh 2020). Eighty-seven studies (50.9%) did not define close contact and the definition was unclear in four studies. Twenty-nine studies (17%) defined other types of contacts including primary contact, secondary contact, high-risk contact, household contact, social contact, and work contact (see Table 3).

Eighteen studies (10.5%) reported data on the contact duration between close contacts and the index or primary cases (Table 3). The average contact duration ranged from 30 minutes to 8 days across 16 studies that investigated transmission rates using RT-PCR. In two studies that examined transmission using serology (Agergaard 2020, Hong 2020), the durations of contact were two weeks and 258 person-days, respectively. The mean contact duration was either unclear or not reported in 148 studies (90.2%).

A total of 110 studies (64.3%) used RT-PCR as a test method for confirming SARS-CoV-2 positivity, while eight studies (4.8%) exclusively investigated transmission using serology. In 24 studies (14%), both PCR and serology were used to investigate close contact in SARS-CoV-2 transmission. Thirty-one studies (18.1%) did not report the test method used. For PCR, the timing of sample collection varied from within 24 hours to 14 days after exposure to the index or primary case; for serology, this ranged from 2–10 weeks post-exposure. In total, 71 studies (41.5%) reported the timing of sample collection. The timing of sample collection was either not reported or unclear in 100 studies (58.5%).

Twenty-two studies (12.9%) reported Ct values for determining PCR test positivity: ≤40 (eight studies), <37 (five studies), ≤35 (three studies), <38 (two studies), one each for <25, ≤30, <32 and <36 (or 39). Only eight studies reported the Ct values for close contacts in their results – these ranged from 16.03 to 38.

Thirty-two studies reported conducting serological tests to assess transmission of SARS-CoV-2 (Table 4). There was variation

Table 3. Definitions and descriptions of close contacts.

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Abdulrahman 2020	Not defined	Not reported	Not reported
Adamik 2020	Not defined	Other cases in each of the infected households were regarded as secondary cases	Not reported
Agergaard 2020	Not defined	Not reported	2 weeks
Angulo-Bazán 2020	Not defined	Not reported	Not reported
Armann 2020	Not defined	Not reported	Not reported
Arnedo-Pena 2020	**Close contacts** living in the same household of the index case and no other sources of transmission apart from the index case could be found.	Closed contacts from work, social events, relatives live in other household were excluded and index cases live alone.	Not reported
Baker 2020	Not defined	Not reported	Median cumulative time spent with the patient 45 mins (10–720 mins)
Baettig 2020	**Close contact:** Less than 2 m for more than 15 min in the last 48 hours before onset symptom of the COVID-19 positive index patient.	Not reported	<2m for >15 mins 48 hours before onset symptom of the COVID-19 positive index patient
Bao 2020	Not defined	Not reported	Average stay duration of 2.5 hr daily before the COVID-19 outbreak.
Basso 2020	**Close contact:** ≥15 min at ≤2 m, or during AGPs, between HCWs and the non-isolated COVID-19 patient	Not reported	≤2 m for ≥15 min or during AGP
Bays 2020	Not defined	Not reported	Not specified
Bi 2020	**Close contacts** were identified as those who lived in the same apartment, shared a meal, travelled, or socially interacted with an index case 2 days before symptom onset.	Casual contacts (eg, other clinic patients) and some close contacts (eg, nurses) who wore a mask during exposure were not included in this group.	Not specified
Blaisdell 2020	Not defined	Not reported	1 week
Böhmer 2020	High risk if they had cumulative face-to-face contact with a patient with laboratory-confirmed SARS-CoV-2 infection for at least 15 min, had direct contact with secretions or body fluids of a patient with confirmed COVID-19, or, in the case of health-care workers, had worked within 2 m of a patient with confirmed COVID-19 without PPE	All other contacts were classified as low-risk contacts.	Face-to-face for at least 15 minutes, direct contact without PPE
Boscolo-Rizzo 2020	Not defined	Not reported	Not reported
Brown 2020	Not defined	Not reported	Mean in-class time = 50 minutes
Burke 2020	Either at least 10 minutes spent within 6 feet of the patient with confirmed COVID-19 (e.g., in a waiting room) or having spent time in the same airspace (e.g., the same examination room) for 0–2 hours after the confirmed COVID-19 patient.	Not reported	Within 6 feet for at least 10 minutes
Canova 2020	Not defined	Not reported	5 HCWs: >30 minutes 5 HCWs: >15–30 mins 6 HCWs: 5–15 mins 5 HCWs: ≤5 mins
Cariani 2020	Not defined	Not reported	Not reported
Charlotte 2020	Not defined	Not reported	2-hours
Chaw 2020	**Close contact:** Any person living in the same household as a confirmed case-patient or someone who had been within 1 m of a confirmed case-patient in an enclosed space for >15 minutes	Not reported	Within 1m for >15 mins
Chen 2020	**Close contact:** All passengers were regarded as close contacts	Not reported	Flight duration 5 hours approx
Chen 2020a	**Close contacts** are persons who have had close contact with re-positive patients without effective protection with masks, such as living and working together	Not reported	Not specified
Chen 2020b	Not defined	Not reported	Not specified

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Chu 2020	**Community contact:** Any close contact (being within 6 feet of the case-patient) for a prolonged time (>10 minutes); being an office co-worker of the case-patient with close contact of any duration; contact with infectious secretions from the case-patient; or sharing a healthcare waiting room or area during the same time and up to 2 hours after the case-patient was present.	Healthcare contact: Face-to-face interaction between healthcare personnel (HCP) and the case-patient without wearing the full PPE that was recommended at the time of the investigation or potential contact with the case-patient's secretions by HCP without wearing full PPE.	>10 mins to 2 hours
Chen 2020c	Not defined	Not reported	Not reported
Cheng 2020	Close contact was a person who did not wear appropriate PPE while having face-to-face contact with a confirmed case for more than 15 minutes during the investigation period. A contact was listed as a household contact if he or she lived in the same household with the index case. Those listed as family contacts were family members not living in the same household. For health care settings, medical staff, hospital workers, and other patients in the same setting were included; close contact was defined by contacting an index case within 2 m without appropriate PPE and without a minimal requirement of exposure time	Those listed as family contacts were family members not living in the same household.	Within 2 m without PPE, face-to-face contact for >15 minutes
Chu 2020a	Not defined	Not reported	Stayed ≥1 night in the household during case's infectious period
Contejean 2020	**Close contact:** Distance <2 meters for >10 minutes was defined as close contact	Not reported	<2 metres for >10 minutes
COVID-19 National Emergency Response Center 2020	Close contact (or high risk exposure)" was being within 2 meters of a COVID-19 case	Daily contact (or low risk exposure) was defined as having proximity with a person who was a confirmed COVID-19 case, without having had close contact.	Not reported
Danis 2020	All children and teachers who were in the same class as the symptomatic pediatric case were considered as **high risk contacts** and were isolated at home. **Moderate/high risk:** Person who had prolonged (>15 min) direct face-to-face contact within 1 m with a confirmed case, shared the same hospital room, lived in the same household or shared any leisure or professional activity in close proximity with a confirmed case, or travelled together with a COVID-19 case in any kind of conveyance, without appropriate individual protection equipment.	**Low risk:** Person who had a close (within 1 m) but short (< 15 min) contact with a confirmed case, or a distant (> 1 m) but prolonged contact in public settings, or any contact in private settings that does not match with the moderate/high risk of exposure criteria. **Negligible risk:** Person who had short (< 15 min) contact with a confirmed case in public settings such as in public transportation, restaurants and shops; healthcare personnel who treated a confirmed case while wearing appropriate PPE without any breach identified.	4 days in chalet
Dattner 2020	Not defined	Not reported	Not reported
de Brito 2020	**Close contact:** Close and prolonged contact in the same room	Not reported	Not specified
Deng 2020	Not defined	Not reported	Not reported
Desmet 2020	Not defined	Not reported	Not reported
Dimcheff 2020	**Close contact:** Within 2 m or 6 feet) with an individual with confirmed COVID-19 for >15 minutes with the example being exposed to a family member at home who has had a positive COVID-19 nasal swab	Not reported	Within 2m for >15 mins
Dong 2020	Not defined	Not reported	Not reported
Doung-ngern 2020	**High-risk** if they were family members or lived in the same household as a COVID-19 patient, if they were within a 1-meter distance of a COVID-19 patient longer than 15 minutes; if they were exposed to coughs, sneezes, or secretions of a COVID-19 patient and were not wearing protective gear, such as a mask; or if they were in the same closed environment within a 1-meter distance of a COVID-19 patient longer than 15 minutes and were not wearing protective gear	Not reported	<15 min vs >15 min, <1m vs >1m
Draper 2020	Close contact was defined as anyone who had face-to-face contact with a confirmed COVID-19 case for more than 15 minutes cumulatively or continuously (e.g. household setting or healthcare setting without appropriate use of personal protective equipment) or who was in the same room with an infectious case for more than 2 hours (e.g. school room, workplace) while a case was symptomatic or during the 24 hours preceding symptom onset. Aircraft close contacts included passengers seated in the same row as, or in the two rows in front of or behind, an infectious case. If the case was a crew member, the passengers in the area in which the crew member worked were classified as close contacts. Passengers disembarking from cruise ships with high incidence of COVID-19 were also classified as close contacts for surveillance purposes.	Not reported	Not reported

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Dub 2020	**Close household contact**, i.e. an individual sharing the main residence of the secondary case	A regular household contact, i.e. an individual who would regularly host or stay in the same residence of a secondary case (step-sibling, divorced parent and new partner). Extended contact, i.e. an individual who would have frequent contact with the secondary case around and after the exposure, for example, grandparents who were involved in caring of the secondary case, according to parents' reports.	<2 meters for >10 minutes
Expert Taskforce 2020	**Close contact:** Cabinmates of confirmed case-patients	Not reported	Not specified
Fateh-Moghadam 2020	Contact of a COVID-19 case has been considered any person who has had contact with a COVID-19 case within a time frame ranging from 48 hours before the onset of symptoms of the case to 14 days after the onset of symptoms	Not reported	Not reported
Firestone 2020	**Close contact:** Being within 6 feet of a patient with laboratory-confirmed COVID-19 infection for ≥15 minutes	Not reported	Within 2m for >15 mins
Fontanet 2020	Not defined	Not reported	Not reported
Fontanet 2020a	Not defined	Not reported	Not reported
Gan 2020	Not defined	Not reported	Not reported
Ghinai 2020	Not defined	Not reported	Not reported
Gong 2020	**Close contact:** Anyone who was closely in contact with a suspected, confirmed and asymptomatic case without effective personal protection (classified protection according to the contact situation, including gloves, medical protective masks, protective face screens, isolation clothing, etc.) since onset of symptoms in the suspected case and confirmed case or the day asymptomatic case's specimens were collected. The close contact included: (i) living, working, or studying in one house or classroom, (ii) diagnosing, treating, or visiting cases in hospital ward, (iii) being within short distance in the same vehicle, (iv) other situations assessed by the field investigators.	Not reported	Not reported
Gu 2020	Not defined	Not reported	5 hrs, no natural ventilation or face masks; distance between each other <0.5 m
Hamner 2020	**Close contact:** Within 6 feet of infected case	Not reported	2.5 hrs within 2 m
Han 2020	**Close contact:** Travel was defined as someone who was in close contact with a confirmed case for over three hours as they traveled to another region aside from Region A. Close contact: meal was defined as someone who was in close contact with a confirmed case for over 30 minutes after having a meal together.	A casual contact was defined as someone who spent several minutes with a confirmed case within the same space without any mask on (or a person was established as a contact by an Epidemic intelligence Officer).	30 mins to 3 hours
Heavey 2020	**Close contact:** Any individual who has had greaterthan 15 minutes face-to-face (<2 meters distance*) contact with a case, in any setting.	Casual contact: Any individual who has shared a closed space with a case for less than two hours.	Up to 2 hours in duration
Helsingen 2020	Not defined	Not reported	Not reported
Hendrix 2020	Not defined	Not reported	Not reported
Hirschman 2020	**Close contact:** Within 6 feet of an infected person for at least 15 minutes starting from 2 days before illness onset.	Not reported	"Hours"
Hobbs 2020	**Close contact:** Within 6 feet for ≥15 minutes) with a person with known COVID-19, school or child care attendance, and family or community exposures ≤14 days before the SARS-CoV-2 test	Not reported	Within 2 m for ≥15 minutes
Hoehl 2020	Not defined	Not reported	Not reported
Hong 2020	Anyone who ever came within 2 m of a diagnosed patient without the use of effective personal protective equipment	Not reported	258 person-days

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Hu 2020	**Close contacts** were defined as individuals who had close-proximity interactions (within 1 meter) with clinically suspected and laboratory-confirmed SARS-CoV-2 cases, for the period from 2 days before, to 14 days after, the potential infector's symptom onset. For those exposed to asymptomatic subjects, the contact period was from 2 days before, to 14 days after, a respiratory sample was taken for real-time RT-PCR testing. Close contacts included, but were not limited to, household contacts (i.e., household members regularly living with the case), relatives (i.e., family members who had close contacts with the case but did not live with the case), social contacts (i.e., a work colleague or classmate), and other close contacts (i.e., caregivers and patients in the same ward, persons sharing a vehicle, and those providing a service in public places, such as restaurants or movie theatres)	Not reported	Not reported
Hua 2020	Not defined	Not reported	
Huang 2020	**Close contacts** quarantined at home or hospital	Not reported	Not reported
Huang 2020a	Not defined	Not reported	Not reported
Islam 2020	Close contact was defined as individuals who were closely linked by contact tracing and were considered a close contact group provided that no PPE was worn having direct face to face contacts.	Household contacts were defined as individuals who lived and were sharing the same room and same apartment in the same household. Family contacts were those who are the members of the same family but not living in the same household.	Face-to-face
Jia 2020	A **close contact** was defined as a person who did not take effective protection against a suspected or confirmed case 2 d before the onset of symptoms or an asymptomatic infected person 2 d before sampling.	Not reported	Not reported
Jiang 2020	**Close contacts:** Lived with the patients and individuals who had contact with the patients within 1 meter without wearing proper personal protection. Ct value ≥40 was considered negative. The maximum likelihood phylogenetic tree of the complete genomes was conducted by using RAxML software with 1000 bootstrap replicates, employing the general time-reversible nucleotide substitution mode	Not reported	1 m
Jing 2020	A **close contact** was defined as an individual who had unprotected close contact (within 1 m) with a confirmed case within 2 days before their symptom onset or sample collection. Individuals who were linked by contact tracing were considered a close contact group	Not reported	Not reported
Jing 2020a	Not defined	Not reported	Not reported
Jones 2020	**Close contacts** were defined by analysis of video footage for player interactions and microtechnology (GPS) data for proximity analysis.	Not reported	Within 1 m, face-to-face for ≥3 secs
Kang 2020	Not defined	Not reported	Not reported
Kant 2020	Not defined	Not reported	Not reported
Kawasuji 2020	Not defined	Not reported	Not reported
Khanh 2020	**Close contact:** <2 m distance for >15 minutes. Successfully traced passengers and crew members were interviewed by use of a standard questionnaire, tested for SARS-CoV-2	Not reported	<2 m distance for >15 minutes.
Kim 2020	Not defined	Household contact: Occurring at least 1 day after but within 14 days from the last point of exposure.	2 days during the presymptomatic period and 1 day during the symptomatic period of the index case.
Kim 2020a	Not defined	Not reported	2 hrs to 4 days
Kim 2020b	**Contact** was defined as presence in the same room with COVID-19 confirmed patients, or in the same outpatient clinic or examination room, 30 minutes before and after COVID-19 confirmed patients. Within 2 m of confirmed patients (via CCTV)	Not reported	Within 2 m of confirmed patients for 30 mins
Kumar 2020	Not defined	Not reported	Not reported
Kuwelker 2020	Not defined	Household members were defined as individuals who resided in the same household as the index case.	Not reported

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Kwok 2020	**Close contacts** referred to anyone who: (i) provided care to the case (including a family member or healthcare worker) or had other close physical contact; or (ii) stayed at the same place (including household members or visitors) while the case was ill.	Not reported	Not reported
Ladhani 2020	Not defined	Not reported	Not reported
Ladhani 2020a	Not defined	Not reported	Not reported
Laws 2020	Not defined	Not reported	Unclear
Laxminarayan 2020	High-risk contacts had close social contact or direct physical contact with index cases without protective measures High-risk travel exposures—defined as close proximity to an infected individual in a shared conveyance for ≥6 hours	Low-risk contacts were in the proximity of index cases but did not meet criteria for high-risk exposure	Not reported
Lee 2020	Not defined: Frequent close contact	Not reported	>1 m
Lee 2020a	Close contact (household contact)	Not reported	Mean contact period was calculated to be 7.7 days.
Lewis 2020	Not defined	Household contacts were defined as all persons living in the same household as the primary patient.	Not reported
Li 2020	Not defined	Not reported	Unclear
Li 2020a	Not defined	Not reported	Not reported
Li 2020b	**Close contact** was defined as an act of sharing a meal, party, vehicle or living room with a confirmed or latently infected patient within 14 days.	Not reported	Not reported
Li 2020c	**Close contacts** were mainly those who have not take effective protection from close contact with the suspected and confirmed cases 2 days before symptoms appeared, or the asymptomatic infected persons 2 days before the specimen collection.	Not reported	Not reported
Li 2020d	Not defined	Not reported	Not reported
Liu 2020	Not defined	Not reported	Unclear
Liu 2020a	Direct contact with patients with neo-coronary pneumonia (within 1 m)	Not reported	Within 1m for 2.5 hrs
Liu 2020b	**Close contacts** were defined by the China Prevention and Control Scheme of COVID-19.	Not reported	7.8 (95%CI: 7.0–8.7) close contacts per index case.
Liu 2020c	Not defined	Not reported	Not reported
López 2020	**Close contact:** Anyone who was within 6 feet of a person with COVID-19 for at least 15 minutes ≤2 days before the patient's symptom onset.	Not reported	≤1.83m of a person with COVID-19 for at least 15 minutes ≤2 days before the patient's symptom onset
Lopez Bernal 2020	Household contacts were defined as those living or spending significant time in the same household. Household contacts, others with direct face to face contact and healthcare workers who had not worn recommended PPE	Not reported	Not reported
Lucey 2020	**Close contact:** HCW or patient who spent more than 15 minutes face-to-face within 2 metres of a confirmed case or patients who shared a multi-bedded room with a confirmed case for more than 2 hours.	Not reported	Not reported
Luo 2020	Unclear: The tour coach was with 49 seats was fully occupied with all windows closed and the ventilation system on during the 2.5-hour trip.	Not reported	1 to 4.5m; up to 2.5 hours on a bus
Luo 2020a	**Close contacts:** Anyone who has had contact, without effective protection regardless of duration of exposure, with 1 or more persons with suspected or confirmed COVID-19 any time starting 2 days before onset of symptoms in persons with a suspected or confirmed case, or 2 days before sampling for laboratory testing of asymptomatic infected persons.	Not reported	Not reported
Lyngse 2020	Not defined	Not reported	Not reported
Ma 2020	Not defined	Not reported	Longest contact time: 8 days Shortest contact time: 0 days
Macartney 2020	**Close contacts:** Children or staff with face-to-face contact for at least 15 min, or who shared a closed indoor space for at least 40 min with a case during their infectious period.	Not reported	Face-to-face contact for at least 15 min, or who shared a closed indoor space for at least 40 min

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Malheiro 2020	**Close contacts** (high risk)were defined as individuals who have spent 15 min or more in closeproximity (2 m or less) to, or in a closed space with, a case.	Not reported	Not reported
Maltezou 2020	**Close contact** was defined as a contact of >15 minutes within a distance of <2 m with a COVID-19 case.	Household members were defined as persons living in the same residence.	>15 minutes within <2 m
Maltezou 2020a	**Close contact** was defined as a contact of >15 minutes within a distance of <2 meters with a COVID-19 case	Household contacts were defined as persons either living in the same residence or having close contacts with a family member for >4 hours daily in the family residence.	Household: >4 hours daily Close contact: >15 minutes within <2 m
Mao 2020	Not defined	Not reported	Not reported
Martinez-Fierro 2020	Individual who has had closer than <6 feet for ≥15 min with people with a positive diagnosis for COVID-19, whether they were symptomatic or asymptomatic according to the CDC definition	Not reported	≥15 min at a distance of <1.83m
Mponponsuo 2020	An interaction of >15 minutes at a distance of <1 m	Not reported	>15 minutes at a distance of <1 m
Ng 2020	**Close contacts** were individuals who had contact for at least 30 min within a 2 m distance from the index case.	**Work contacts** were defined as individuals who came into close contact with the index case at work, from 2 days before the onset of symptoms to isolation of the case, to account for pre-symptomatic transmission. **Social contacts** were defined as individuals who came into close contact with the index case, from 2 days before onset of symptoms to isolation of the case, through social activities. Transport contacts were excluded **Lower risk contacts:** Other contacts who were with the index case for 10–30 min within 2 m	At least 30 min within a 2 m
Ning 2020	Not defined	Not reported	Unclear
Njuguna 2020	Not defined	Not reported	Unclear
Ogawa 2020	Not defined	Not reported	Not reported
Paireau 2020	Not defined	Not reported	Not reported
Park 2020	Not defined	Not reported	Not reported
Park 2020a	High-risk contact (household contacts of COVID-19 patients, healthcare personnel)	Household contact was a person who lived in the household of a COVID-19 patient and a nonhousehold contact was a person who did not reside in the same household as a confirmed COVID-19 patient.	Not reported
Park 2020b	Not defined	Not reported	Not reported
Passarelli 2020	Not defined	Not reported	Not reported
Patel 2020	Not defined	Not reported	Not reported
Pavli 2020	**Close contacts** were defined as persons sitting within a distance of <2 m for >15 min, including passengers seated two seats around the index case and all crew members and persons who had close contact with the index case.	Not reported	<2 m for >15 min
Phiriyasart 2020	Close contact was defined as a person who had at least one of these following criteria : (i) a person who came into close (within 1 meter) contact with, or had a conversation with any patient for >5 minutes, or was coughed or sneezed on by any patient when he/she did not wear appropriate personal protective equipment (PPE), e.g. a face mask, (ii) a person who was in an enclosed space without proper ventilation, e.g. in the same air-conditioned bus/air-conditioned room as any patient , and was within one meter of any patient for >15 minutes without wearing appropriate PPE. High-risk close contact was defined as a close contact who was likely to contract the virus from any patient through exposure to respiratory secretions of any patient while not wearing PPE according to standard precautions.	A low-risk close contact was defined as a close contact who was less likely to contract the virus from any patient. This includes close contacts who have not met the definition for high-risk close contacts.	Not reported
Poletti 2020	Not defined	Not reported	Not reported
Pung 2020	**Close contacts:** People who spend a prolonged time within 2 m of a confirmed case	**Other contacts:** People who had some interactions with the case.	Unclear

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Pung 2020a	Unclear: Close household contacts	Not reported	Unclear
Qian 2020	Four categories of infected individuals were considered based on their relationship: family members, family relatives, socially connected individuals, and socially non-connected individuals	Not reported	Not reported
Ravindran 2020	**Close contact:** Face-to-face contact for greater than 15 minutes cumulative in the period extending from 48 hours before onset of symptoms in a confirmed case; or sharing of closed space with a confirmed case for a prolonged period of time in the period extending from 48 hours before onset of symptoms in a confirmed case.	Not reported	Face-to-face contact for at least 15 min, or who shared a closed indoor space for prolonged period 48 hrs before onset of symptoms
Razvi 2020	Not defined	Not reported	Not reported
Rosenberg 2020	Not defined	Not reported	
Roxby 2020	Not defined	Not reported	Not reported
Sang 2020	Not defined	Not reported	Not reported
Schumacher 2020	Close contact: Approximately 30–90 seconds in close proximity (<1.5 m) of other players	Close social contacts (including sharing a car)	30–90 seconds in close proximity (<1.5 m)
Schwierzeck 2020	Not defined	Not reported	Not reported
Shah 2020	Household contact was defined as contact sharing same residential address.	Not reported	Not reported
Shen 2020	**Close contacts** defined as individuals who had close, prolonged, and repeated interactions with the 2 source cases (Cases 2 and 3).	All other contacts are defined as casual contacts.	Not reported
Sikkema 2020	Not defined	Not reported	Not reported
Son 2020	Not defined	A contact was defined as anyone who was in contact with a confirmed case from a day before the symptoms occurred, in a manner that offered the potential for transmission through respiratory droplets	Not reported
Song 2020	Unclear: shared the same bedroom, had dinner together	Not reported	Not reported
Speake 2020	2 rows in front and behind infectious passenger on an airplane	Not reported	Unclear
Stein-Zamir 2020	Not defined	Not reported	Not reported
Sugano 2020	Not defined	Not reported	Unclear
Sun 2020	Not defined	Not reported	Not reported
Taylor 2020	Not defined	Not reported	Unclear
Teherani 2020	Household contacts (HCs) were defined as an adult (18 years) or a child (<18 years) who resided in the home with the SIC at the time of diagnosis.	Not reported	Not reported
Thangaraj 2020	Not defined	Not reported	Unclear
Torres 2020	Not defined	Not reported	Unclear
Tshokey 2020	Unclear: Close friends, roommates, flight seat partner, spouse or partner, cousin, physician, tour driver	**Primary contacts:** Individuals coming in some form of contact with the confirmed cases such as conveyance in the same cars/flights, encounter in clinics, serving meals, or providing housekeeping services in hotels. **Secondary contacts:** Individuals coming in contact with the primary contacts	Unclear
van der Hoek 2020	Not defined	Not reported	
Wang 2020	Not defined	Not reported	Unclear
Wang 2020a	Not defined	Not reported	Unclear
Wang 2020b	Close contact was defined as being within 1 m or 3 feet of the primary case, such as eating around a table or sitting together watching TV.	Not reported	Unclear
Wee 2020	Not defined	Not reported	Within 2 m of the index case for a cumulative time of ≥15 minutes, or who had performed AGPs without appropriate PPE.

F1000Research 2021, 10:280 Last updated: 04 NOV 2022

Study ID	Definitions of close contacts	Definition of other contacts	Contact duration & proximity
Wendt 2020	**High-risk contacts:** >15 min face-to-face contact, sitting in a row behind physician for 45 mins, transfer in an ambulance (45-min drive).	Not reported	>15 min face-to-face contact
Wolf 2020	Not defined	Not reported	Not specified
Wong 2020	**Contact case** was defined as a patient or staff who stayed or worked in the same ward as the index patient. Patients who shared the same cubicle with the index case were considered as 'patient close contact'. **Staff close contact:** Staff who had contact within 2 m of the index case for a cumulative time of >15 min, or had performed AGPs, without 'appropriate' PPE.	Casual contacts: All staff and patients who did not fulfill the pre-defined criteria for close contacts. Casual/low-rosk contact: HCW wearing a facemask or respirator only and have prolonged close contact with a patient who was wearing a facemask, or HCW using all recommended PPE or HCW (not using all recommended PPE) who have brief interactions with a patient regardless of whether patient was wearing a facemask. Patient close contacts were quarantined into an AIIR (or quarantine camp if the patient was deemed clinically stable to be discharged from hospital) for 14 days.	Within 2 m of the index case for a cumulative time of >15 min
Wood 2020	Not defined	Not reported	Not reported
Wu 2020	**Close contact:** Been within 1 metre of a confirmed case, without effective PPE, within the period since 5 days before the symptom onset in the index case or since 5 days before sampling if the index case was asymptomatic.	Not reported	Within 1 metre of a confirmed case, without effective PPE
Wu 2020a	Household contacts were defined as person who spent at least 1 night in the house after the symptom onset of the index patient. A household was defined as ≥2 people living together in the same indoor living space. A household index was the first person to introduce SARS-CoV-2 into the household.	Not reported	At least 1 night
Xie 2020	**Close contact:** An individual who has not taken effective protection when in proximity of suspected or confirmed cases 2 days before the onset of symptoms or 2 days before the collection of asymptomatic specimens.	Not reported	Unclear
Xin 2020	Close contacts were defined as persons who had a short-range contact history for 2 days before the onset of symptoms in COVID-19-suspected and -confirmed cases, or 2 days before the collection of samples from asymptomatic cases without taking effective protective measures, such as family members in the same house, direct caregivers, and medical staff who provided direct medical care, colleagues in the same office or workshop, etc.	The effective contact duration for the close contacts was defined as the contact days with index patients with confirmed COVID-19, which was calculated as the last contact date minus the start contact date, and all dates were corresponding to the definition of close contacts	The median effective contact duration with patients with COVID-19 was 4 (IQR: 1–6) days, with 57 (53.8%) experiencing effective contact between 3 and 11 days, and 9 (8.5%) with effective contact duration > 11 days
Yang 2020	**Close contacts:** Uunprotected exposure.	Candidate contacts: Teachers and classmates	Not reported
Yau 2020	Close unprotected contact with someone who has tested positive for COVID-19 in the last 14 days	Not reported	Unclear
Ye 2020	Not defined	Not reported	Not reported
Yoon 2020	**Close contact** was defined as a person who had face-to-face contact for >15 minutes or who had direct physical contact with the index case-patient. Persons who used the same shuttle bus were also considered to be close contacts.	Not reported	Face-to-face contact for >15 minutes or direct physical contact
Yousaf 2020	Not defined	Not reported	Not reported
Yu 2020	**Close contacts** were defined as those who lived in the same household, shared meals, traveled or had social interactions with a confirmed case two days before the onset of COVID-19 symptoms	Not reported	Not reported
Yung 2020	Not defined	Not reported	Not reported
Zhang 2020	Not defined	Not reported	Not reported
Zhang 2020a	**Close contact:** Refers to a person who had contact with index case without using proper protection during 2 days before the index case was tested.	Not reported	Not reported
Zhang 2020b	Not defined	Not reported	Not reported
Zhang 2020c	**Close contacts** were individuals who lived with a PCR-confirmed case or interacted with a case within 1 metre from the case without any personal protections.	Not reported	Within 1m of case
Zhang 2020d	Not defined	Not reported	Not reported
Zhuang 2020	Not defined	Not reported	Not reported

Table 4. Description of serological tests in close contact studies of SARS-CoV-2.

Study ID	Serological test	Description of test	Thresholds for serological positivity
Agergaard 2020	IgG and IgM	iFlash and DiaSorin	iFlash SARS-CoV-2 N/S IgM/IgG cut-off: ≥12 AU/ml = positive. DiaSorin SARS-CoV-2 S1/S2 IgG cut-off: ≥15 AU/ml = positive, 12 < x < 15 AU/ml = equivocal, and ≤12 AU/ml = negative.
Angulo-Bazán 2020	IgG and IgM	Coretests ® COVID-19 IgM / IgG Ab Test (Core Technology Co. Ltd), a lateral flow immunochromatographic test that qualitatively detects the presence of antibodies against SARS-CoV-2, with a sensitivity and specificity reported by the manufacturer for IgM / IgG of 97.6% and 100%, respectively	Not reported
Armann 2020	IgG	Diasorin LIAISON® SARS-CoV-2 S1/S2 IgG Assay). All samples with a positive or equivocal LIAISON® test result, as well as all samples from participants with a reported personal or household history of a SARS-CoV-2 infection, were re-tested with two additional serological tests: These were a chemiluminescent microparticle immunoassay (CMIA) intended for the qualitative detection of IgG antibodies to the nucleocapsid protein of SARS-CoV-2 (Abbott Diagnostics® ARCHITECT SARS-CoV-2 IgG) (an index (S/C) of < 1.4 was considered negative whereas one >/= 1.4 was considered positive) and an ELISA detecting IgG against the S1 domain of the SARS-CoV-2 spike protein (Euroimmun® Anti-SARS-CoV-2 ELISA) (a ratio < 0.8 was considered negative, 0.8–1.1 equivocal, > 1.1 positive) Participants whose positive or equivocal LIAISON® test result could be confirmed by a positive test result in at least one additional serological test were considered having antibodies against SARS-CoV_x0002_2.	Antibody levels > 15.0 AU/ml were considered positive and levels between 12.0 and 15.0 AU/ml were considered equivocal.
Baettig 2020	IgG and IgM	Used commercially available immunochromatography rapid test with SARS-CoV-2 protein-specific IgM and IgG. This test was performed according to the manufacturers' instructions with a reported sensitivity and specificity of 93% and 95%, respectively.	Not reported
Basso 2020	IgG and IgM	Sera were collected approximately 3 weeks following exposure for the detection of antibodies against SARS-CoV-2. EDI Novel Coronavirus COVID-19 IgG and IgM ELISA (Epitope Diagnostics, Inc., San Diego, CA, USA) were used for initial testing, and supplemented with tests from DiaSorin (LIAISON SARS-CoV-2 S1/S2 IgG test), Abbott (Alinity i SARS-CoV-2 IgG), Roche (Elecsys Anti-SARS-CoV-2) and Wantai (WANTAI SARS-CoV-2 Ab ELISA).	Not reported
Brown 2020	IgG and IgM	ELISA (authors referenced another study)	Reciprocal titers of >400 to be positive and reciprocal titers of >100 but <400 to be indeterminate.
Chen 2020b	IgG and IgM	In-house enzyme immunoassay (EIA). 96-well plates were coated with 500 ng/mL of recombinant RBD or NP protein overnight, incubating with diluted serum samples at 1:20. Plates were incubated with either anti-human IgM or IgG conjugated with HRP. Optical density (OD) value (450nm-620nm) was measured.	Preliminary cut-off values were calculated as the mean of the negative serum OD values plus 3 standard deviation (SD) from 90 archived healthy individuals in 2019. A close contact was considered seropositive if OD of 1:20 diluted serum was above the cut-off values for either IgM or IgG against both RBD and NP protein
Chu 2020	IgG and IgM	Serum samples were tested at CDC using a SARS-CoV-2 ELISA with a recombinant SARS-CoV-2 spike protein (courtesy of Dr. Barney Graham, National Institutes of Health, Bethesda, MD, USA) as an antigen. Protein ELISA 96-well plates were coated with 0.15 µg/mL of recombinant SARS-CoV-2 spike protein and ELISA was carried out as previously described. An optimal cutoff optical density value of 0.4 was determined for >99% specificity and 96% sensitivity. Serum samples from the case-patient were used as a positive control and commercially available serum collected before January 2020 from an uninfected person as a negative control.	Total SARS-CoV-2 antibody titers >400 were considered seropositive.
Dattner 2020	IgG	Abbott SARS-CoV-2 IgG, whose specificity was estimated as ~100% and whose sensitivity at ≥ 21 days was estimated as ~85%	Not reported
de Brito 2020	IgG and IgM	Chemiluminescence 4 weeks after contact with the index case	Not reported
Dimcheff 2020	IgG	Serum IgG to thD4:D12e nucleoprotein of SARS-CoV-2 was measured using a Federal Food and Drug Administration (FDA) emergency-use–authorized chemiluminescent microparticle immunoassay performed on an automated high throughput chemistry immunoanalyzer (Architect i2000SR, Abbott Laboratories, Abbott Park, IL). The sensitivity of this assay is reported to be 100% with a specificity of 99% at >14 days after symptom onset in those infected with SARS-CoV-2.1 At 5% prevalence, the positive predictive value is 93.4% and the negative predictive value is 100%	Results are reported in a relative light units (RLU) index; a value ≥1.4 RLU is considered a positive antibody response.
Dub 2020	IgG	IgG antibodies to SARS-CoV-2 nucleoprotein (The Native Antigen Company, United Kingdom) were measured with a fluorescent bead-based immunoassay (manuscript in preparation). Antigen was conjugated on MagPlex Microspheres and bound IgG antibodies were identified by a fluorescently labeled conjugated antibody (R_x0002_Phycoerythrin-conjugated Goat Anti-Human IgG, Jackson Immuno Research, USA). The plate was read on Luminex® MAGPIX® system. xPONENT software version 4.2 (Luminex®Corporation, Austin, TX) was used to acquire and analyze data. Median fluorescent intensity was converted to U/ml by interpolation from a 5-parameter logistic standard curve. The specificity and sensitivity of the assay was assessed using receiver operator curve (ROC) with 100% specificity and 97.9% sensitivity	MNT titre of ≥ 6 considered positive FMIA titre 3·4 U/ml considered positive

Study ID	Serological test	Description of test	Thresholds for serological positivity
Fontanet 2020	IgG	Antibody responses to SARS-CoV-2 using several assays developed by Institut Pasteur : an ELISA N assay, detecting antibodies binding to the N protein; a S-Flow assay, which is a flow-cytometry based assay detecting anti-S IgG; and a LIPS assay, which is an immunoprecipitation-based assay detecting anti-N and anti-S1 IgG.	Participants were considered seropositive for SARS-CoV-2 if any test was positive, since all tests had a specificity higher than 99% with the cut-offs chosen for positivity
Fontanet 2020a	Not specified	Serological testing was conducted using the S-Flow assay, a flow_x0002_cytometry-based serological test developed by the Institut Pasteur. The assay is based on the recognition of the SARS-CoV-2 Spike protein expressed at the surface of 293T cells. In previous studies, the sensitivity of the assay was estimated at 99.4% (95% CI = 96.6% - 100%) on a panel of 160 RT-PCR confirmed mild forms of COVID-1928, while its specificity was found to be 100% (one-sided 97.5% CI = 97.4% - 100%) on a panel of 140 pre-epidemic sera	Not reported
Gu 2020	IgG	Not described	Not reported
Helsingen 2020	IgG	Measurement of IgG antibodies was performed with a multiplex flow cytometric assay known as microsphere affinity proteomics (MAP)	Not specified. Referenced
Hong 2020	IgG and IgM	Qualitative colloidal gold assay (Innovita (Tangshan) Biological Technology, Co., Ltd, Tangshan, China), following manufacturers' instructions. The sensitivity of the assay was 87.3% (95%CI 80.4–92.0%), and the specificity was 100% (95%CI 94.20–100%) according to the instructions of the assay.	Not reported
Kuwelker 2020	IgG	A two-step ELISA was used for detecting SARS-CoV-2-specific antibodies, initially by screening with receptor-binding domain (RBD) and then confirming seropositivity by spike IgG. Endpoint titres were calculated as the reciprocal of the serum dilution giving an optical density (OD) value=3 standard deviations above the mean of historical pre-pandemic serum samples. Individuals with no antibodies were assigned a titre of 50 for calculation purposes. **Neutralisation assays were used to quantify SARS-CoV-2-specific functional antibodies.** VN titres were determined as the reciprocal of the highest serum dilution giving no CPE. Negative titres (<20) were assigned a value of 10 for calculation purpose.	Not specified.
Lewis 2020	Not specified	ELISA (authors referenced another study)	Not specified
Luo 2020a	IgG and IgM	Not described	Asymptomatic: Specific IgM detected in serum. Symptomatic: Detectable SARS-CoV-2–specific IgM and IgG in serum, or at least a 4-fold increase in IgG between paired acute and convalescent sera.
Macartney 2020	IgA, IgG, IgM	SARS-CoV-2-specific IgG, IgA, and IgM detection was done using an indirect immunofluorescence assay (IFA) that has a sensitivity compared with nucleic acid testing of detecting any of SARS-CoV-2-specific IgG, IgA, or IgM when samples were collected at least 14 days after illness onset of 91·3% (95% CI 84·9–95·6) and specificity of 98·9% (95% CI 98·4–99·3%; MVNO, personal communication).	Not specified
Martinez-Fierro 2020	IgG and IgM	IgM and IgG against SARS-CoV-2 were determined using a total blood sample through a 2019 nCov IgG/IgM rapid test (Genrui Biotech, Shenzen, China)	Not specified
Ng 2020	Not specified	human ACE-2 (hACE2) protein (Genscript Biotech, New Jersey, United States) was coated at 100 ng/well in 100 mM carbonate-bicarbonate coating buffer (pH 9.6). 3ng of horseradish peroxidase (HRP)-conjugated recombinant receptor binding domain (RBD) from the spike protein of SARS-CoV-2 (GenScript Biotech) was pre-incubated with test serum at the final dilution of 1:20 for 1 hour at 37°C, followed by hACE2 incubation for 1 h at room temperature.Serum samples were tested with a surrogate **viral neutralising assay** for detection of neutralising antibodies to SARS-CoV-2.	A positive serological test result was concluded if the surrogate viral neutralising assay for a particular sample resulted in inhibition of 30% or greater (98·9% sensitivity and 100·0% specificity)
Ogawa 2020	IgG	Abbott® (Abbott ARCHITECT SARS-CoV-2 IgG test, Illinois, USA)	Not specified
Poletti 2020	IgG	Not described	Not specified
Razvi 2020	IgG and IgM	Blood samples were analysed on the day of collection using the Roche Elecsys Anti-Sars-CoV-2 serology assay. This electrochemiluminescent immunoassay is designed to detect both IgM and IgG antibodies to SARS-CoV-2 in human serum and plasma and has been shown to have a high sensitivity and specificity	Not specified
Schumacher 2020	IgG and IgM	SARS-CoV-2-specific antibodies were measured in serum samples using an electrochemiluminescence immunoassay (Elecsys® Anti-SARS-CoV-2, Roche Diagnostics, Rotkreuz, Switzerland).	Cut-off indices ≤1 reported as negative and indices >1 as positive.
Torres 2020	IgG and IgM	Novel Coronavirus (2019-nCoV) IgG/IgM Test Kit (Colloidal gold) from Genrui Biotech Inc. The study nurse and/or technician viewed the photo provided by the participant along with the participant's self-report as to the visibility of the three bands, and determined whether the tests were IgG+, IgM+, IgG & IgM+, Negative, Invalid, or Indeterminate. Participants were asked to attach a photo of the test after 15 minutes had elapsed and self-report the appearance of the three lines, G (IgG), M (IgM), and C (test control)	Colour-coded - self-administered test: self-reporting the appearance of the three lines, G (IgG), M (IgM), and C (test control)

Study ID	Serological test	Description of test	Thresholds for serological positivity
van der Hoek 2020	IgG	Fluorescent bead-based multiplex-immunoassay. Referenced	A cut-off concentration for seropositivity (2.37 AU/mL; with specificity of 99% and sensitivity of 84.4%) was determined by ROC-analysis of 400 pre-pandemic control samples
Wendt 2020	IgA and IgG	ELISA (Euroimmun, Lübeck, Germany), following the manufacturer's instructions.	Inconclusive (≥0.8 and <1.1) or Positive (≥1.1
Yang 2020	IgA, IgG, IgM	Serum immunoglobulin (Ig) antibody against the SARS-CoV-2 surface spike protein receptor-binding domain (RBD) was measured using a chemiluminescence kit (IgM, IgG, and total antibody, Beijing Wantai Biotech, measured by cut-off index [COI]) or ELISA kit (IgA, Beijing Hotgen Biotech, measured by optical density at 450/630 nm [OD450/630]). The cut-off for seropositivity was set according to the manufacturer's instruction, verified using positive (169 serum specimens from confirmed COVID-19 patients) and negative (128 serum specimens from healthy persons) controls, and both of sensitivity and specificity were 100%. **Virus neutralization assays** were performed using SARS-CoV-2 virus strain 20SF014/vero-E6/3 (GISAID accession number EPI_ISL_403934) in biosafety level 3 (BSL-3) laboratories. Neutralizing antibody (NAb) titer was the highest dilution with 50% inhibition of cytopathic effect, and a NAb titer of ≥1:4 was considered positive.	Specimens with COI>1 (IgM, IgG, or total antibody), OD450/630 > 0.3 (IgA) were considered positive.
Zhang 2020b	IgG and IgM	SARS-CoV-2-specific IgM and IgG were tested by paramagnetic particle chemiluminescent immunoassay using iFlash-SARS-CoV-2 IgM/IgG assay kit (Shenzhen YHLO Biotech Co., Ltd) and iFlash Immunoassay Analyzer (Shenzhen YHLO Biotech Co., Ltd). The specificity and sensitivity of SARS-CoV-2 IgM and IgG detection were also evaluated	Not specified

in the description of the tests. Fifteen studies determined the antibody responses to SARS-CoV-2 spike proteins using Immunoglobulin G (IgG) and IgM while 11 used only IgG. In 17 studies, the threshold for serological positivity was not reported. Three studies (Kuwelker 2020, Ng 2020, Yang 2020) performed neutralisation assays to confirm positive serologic samples. In one study (Torres 2020), study participants self-administered the serological tests.

Three studies (Ladhani 2020a, Speake 2020, Yang 2020) performed viral culture, while 10 studies (Böhmer 2020, Firestone 2020, Jiang 2020, Ladhani 2020a, Lucey 2020, Pung 2020, Sikkema 2020, Speake 2020, Taylor 2020, Wang 2020) performed genome sequencing (GS) plus phylogenetic analysis.

Frequency of SARS-CoV-2 attack rates (ARs)

Twenty-three studies reported data on attack rates using RT-PCR (Table 6). The settings included healthcare (n=3), household (n=8), public transport (n=2), educational settings (n=3). In one study of 84 children in daycare centres during the first few weeks of the pandemic (Desmet 2020), the AR was 0%; similar results were reported in another study of hospital healthcare workers

Table 6. Main results of included studies.

Study ID	Type of transmission	Total number of contacts	Cycle threshold	Attack rates and/or secondary attack rates (SAR)	Notes
Abdulrahman 2020	Community	***Eid Alfitr*** Pre-: 71,553; Post-: 76,384 ***Ashura*** Pre-: 97,560; Post-: 118,548	Not reported	**Eid Alfitr** Pre-: 2990 (4.2%); Post-: 4987 (6.7%); p <0.001 **Ashura** Pre-: 3571 (3.7%); Post-: 7803 (6.6%); p <0.001	The rates of positive tests was significantly greater after religious events
Adamik 2020	Household	Unclear	Not reported	Unclear: 3553 (AR 26.7%)	
Agergaard 2020	Household	PCR: 5 Serology: 5	Not reported	Index case plus 1 family member tested positive-PCR All 5 displayed a serological SARS-CoV-2 N/S IgG response	
Angulo-Bazán 2020	Household	52 households (n=236 people) 4.5±2.5 members per household	Not reported	Serology: Amongst cohabitants, SAR was 53.0% (125 cases): 77.6% of cases were symptomatic	Convenience sampling, no component of temporality, selection bias
Armann 2020	Local Household	2045 in Phase 1 1779 in Phase 2	N/A	Serology: 12/2045 (0.6%) Serology: 12/1779 (0.7%)	
Arnedo-Pena 2020	Household	745	Not reported	11.1% (95% CI 9.0–13.6)	
Baker 2020	Nosocomial	44	Not reported	3/44 (6.8%): 1 of these was also exposed to a household member with COVID-19.	Recall error and bias, report is limited to a single exposure, change in mask policy partway through the exposure period
Baettig 2020	Local	55	Not reported	Serologic attack rates: 2/55 (3.6%)	Serological testing was positive for the 2 contacts 14 days after index case
Bao 2020	Community	57 index cases 1895 exposed	Not reported	SAR was 3.3% at the bathing pool, 20.5% in the colleagues' cluster and 11.8% in the family cluster.	Delayed detection of the activity trajectory of the primary case, reporting bias, overlap of close contacts
Basso 2020	Nosocomial	60 HCWs - ≥106 unique high-risk contacts	Not reported	Attack rate: 0/60 (0%) Serology: 0/60 (0%)	Delay in diagnosing index case, recall bias
Bays 2020	Nosocomial	421 HCWs	Not reported	8/421 (1.9%)	In all 8 cases, the staff had close contact with the index patients without sufficient PPE. Hospital staff developing ILI symptoms were tested for SARS-CoV-2, regardless of whether they had contact with an index patient
Bi 2020	Local Household Community	1,296	Not reported	98/1286 (7.6%)	
Blaisdell 2020	Community	1,022	Not reported	1.8% of camp attendees (10 staff members and 8 campers)	Travel was assumed to be from home state but intermediate travel might have occurred
Böhmer 2020	Local Household	241	Not reported	75·0% (95% CI 19·0–99·0; three of four people) among members of a household cluster in common isolation, 10·0% (1·2–32·0; two of 20) among household contacts only together until isolation of the patient, and 5·1% (2·6–8·9; 11 of 217) among non-household, high-risk contacts.	
Boscolo-Rizzo 2020	Household	296	Not reported	74/296 (25.0%, 95% CI 20.2–30.3%)	The prevalence of altered sense of smell or taste was by far lower in subjects negative to SARS-CoV-2 compared to both positives (p < 0.001) and non-tested cases (p < 0.001).

Study ID	Type of transmission	Total number of contacts	Cycle threshold	Attack rates and/or secondary attack rates (SAR)	Notes
Brown 2020	Local	21	Not reported	Serologic attack rate: 2/21 (1%)	Social desirability bias likely
Burke 2020	Household	445	Not reported	0.45% (95% CI = 0.12%–1.6%) among all close contacts, and a symptomatic secondary attack rate of 10.5% (95% CI = 2.9%–31.4%) among household members.	2 persons who were household members of patients with confirmed COVID-19 tested positive for SARS-CoV-2.
Canova 2020	Nosocomial	21	Not reported	0/21 (0%)	
Cariani 2020	Nosocomial	Unclear	33.6 to 38.03	182 out of 1683 (10.8%) tested positive; 27 of whom had close contact with COVID-positive patients	Unclear how many HCWs had close contact; likelihood of recall bias
Charlotte 2020	Community	27	Not reported	19 of 27 (70%) tested positive	High risk of selection bias: The index case-patients were not identified. A majority of patients were not tested for SARS-CoV-2
Chaw 2020	Local Community	1755	Not reported	Close contact: 52/1755 (29.6%) Nonprimary attack rate: 2.9% (95% CI 2.2%–3.8%)	Potential environmental factors were not accounted for: relative household size, time spent at home with others, air ventilation, and transmission from fomites.
Chen 2020	Aircraft	335	Not reported	16/335 (4.8%)	Recall bias. Did not perform virus isolation and genome sequencing of the virus, which could have provided evidence of whether viral transmission occurred during the flight.
Chen 2020a	Local Household	209	Not reported	0/209 (0%)	
Chen 2020b	Nosocomial	105	Not reported	Serology: 18/105 (17.1%)	
Chen 2020c	Local Community Household Nosocomial	2147	Not reported	110/2147 (5.12%)	
Cheng 2020	Household Nosocomial	2761	Not reported	0.70%	
Chu 2020	Community	50 exposed	Not reported	None for antigen or antibody: 0/50 (0%)	Testing was biased toward contacts who knew the case-patient personally (office co-workers) or provided direct care for the case-patient (HCP).
Chu 2020a	Household	526 exposed	Not reported	48 (9%) (CI 7-12%)	Very high risk of selection bias
Contejean 2020	Nosocomial	1344 exposed	Not reported	373 (28%)	
COVID-19 National Emergency Response Center 2020	Local Household Nosocomial	2370	Not reported	13/2370 (0.6%)	There were 13 individuals who contracted COVID-19 resulting in a secondary attack rate of 0.55% (95% CI 0.31–0.96). There were 119 household contacts, of which 9 individuals developed COVID-19 resulting in a secondary attack rate of 7.56% (95% CI 3.7–14.26).
Danis 2020	Local Household	Chalet: 16 School: 172	Not reported	Attack rate: 75% in chalet Attack rate: 0% in school	Only 73 of 172 school contacts were tested - all tested negative
Dattner 2020	Household	3353	Not reported	Attack rates: 25% in children and 44% adults (45% overall) Serology: 9/714 (1.3%)	

Study ID	Type of transmission	Total number of contacts	Cycle threshold	Attack rates and/or secondary attack rates (SAR)	Notes
de Brito 2020	Household	24 exposed	Not reported	RT-PCR: 6/7 (86%); Seropositivity: 18/24 (75%)	
Deng 2020		347	Not reported	25/347 (7.2%)	
Desmet 2020	Local	84	38.8	Attack rate: 0/84 (0%)	Ct reported for only one test result
Dimcheff 2020	Community Nosocomial Household	1476	Not reported	Seroprevalence 72/1476: 4.9% (95% CI, 3.8%–6.1%)	
Dong 2020	Household	259	Not reported	53/259 (20.5%)	
Doung-ngern 2020	Local	211 cases plus 839 non-matched controls	Not reported		
Draper 2020	Local Household Nosocomial	445	Not reported	4/445 (0.9%)	None of the 326 aircraft passengers or 4 healthcare workers who were being monitored close contacts became cases.
Dub 2020	Local Household	121	Not reported	Child index case: No positive cases Adult index case: 8/51 (16%) Serology: 6/101 (5.9%)	
Expert Taskforce 2020	Local	Unclear	Not reported	Attack rate 20.4%	Attack rates were highest in 4-person cabins (30.0%; n = 18), followed by 3-person cabins (22.0%; n = 27), 2-person cabins (20.6%; n = 491), and 1-person cabins (8%; n = 6).
Fateh-Moghadam 2020	Community	6690	Not reported	890/6690 (13.3%)	
Firestone 2020	Local	Unclear	Not reported	41 (80%) interviewed patients with primary event-associated COVID-19 reported having close contact with others during their infectious period, with an average of 2.5 close contacts per patient. 36 (75%) of 48 interviewed patients with primary event-associated cases reported having close contact with persons in their household while infectious, and 17 (35%) reported having other (social/workplace) close contacts while infectious.	
Fontanet 2020	Local	661	N/A	Serology: 171/661 (25.9%, 95%CI 22.6-29.4)	
Fontanet 2020a	Local	510	N/A	Serology: 45/510 (8.8%)	
Gan 2020	Local Household Community	Unclear	Not reported	Not reported	Family clusters accounted for 86.9% (914/1 050) of cases, followed by party dinners (1.1%)
Ghinai 2020	Community	Unclear	Not reported	Unclear	
Gong 2020	Household Community	Unclear	Not reported	Unclear	
Gu 2020	Local	14	Not reported	RT-PCR - 3/14 (21.4%) Serology - 2/14 (14.3%)	
Hamner 2020	Local	60	Not reported	Confirmed: 32/60 (53.3%) Probable: 20/60 (33.3%)	

Study ID	Type of transmission	Total number of contacts	Cycle threshold	Attack rates and/or secondary attack rates (SAR)	Notes
Han 2020	Community	192	Not reported	7/192 (3.7%)	
Heavey 2020	Local	1155	Not reported	0/1155 (0%)	
Helsingen 2020	Local	Training arm: 1,896 Nontraining arm: 1,868	Not reported	11/1896 (0.8%) vs 27/1868 (2.4%); P=0.001	
Hendrix 2020	Local	139 exposed	Not reported	0%	Six close contacts of stylists A and B outside of salon A were identified: four of stylist A and two of stylist B. All four of stylist A's contacts later developed symptoms and had positive PCR test results for SARS-CoV-2. These contacts were stylist A's cohabitating husband and her daughter, son-in-law, and their roommate, all of whom lived together in another household. None of stylist B's contacts became symptomatic.
Hirschman 2020	Household Community	58	Not reported	27/58 (47%)	
Hobbs 2020	Local Household Community	397	Not reported	Not reported	
Hoehl 2020	Local Community	825 children and 372 staff: 7,366 buccal mucosa swabs and 5,907 anal swabs	Not reported	0% viral shedding in children; 2/372 (0.5%) shedding for staff. No inapparent transmissions were observed	Study was conducted in the summer of 2020, when activity of other respiratory pathogens was also low
Hong 2020	Household	431 tests	Not reported	0/13 (0%)	Index cases had lived with their family members without personal protections for a total of 258 person-days.
Hu 2020	Household Community	15648	Not reported	471/15648 (3%)	
Hua 2020	Household	835	Not reported	151/835 (18.1%)	
Huang 2020	Household Community	22	Not reported	7/22 (31.8%)	
Huang 2020a	Local Household Community Nosocomial	3795	Not reported	32/3795 (0.84%)	
Islam 2020	Household Local Community Nosocomial	391	Not reported	The overall secondary clinical attack rate was 4.08 (95% CI 1.95–6.20)	
Jia 2020	Household	Unclear	Not reported	Attack rate 44/583 (7.6%)	
Jiang 2020	Household Community	300	Not reported	6/300 (2%)	
Jing 2020	Household	Unclear	Not reported	Household contacts 13·2% Non-household contacts 2·4%	The risk of household infection was significantly higher in the older age group (≥60 years)

Study ID	Type of transmission	Total number of contacts	Cycle threshold	Attack rates and/or secondary attack rates (SAR)	Notes
Jing 2020a	Household Community	Unclear	Not reported	Close contacts 17.1% to 19% Family members 46.1% to 49.6%	
Jones 2020	Local	128	Not reported	6/128 (4.7%)	
Kang 2020	Local	5517	Not reported	96/5517 (1.7%)	
Kant 2020	Local Community Nosocomial	Not reported	Not reported	Not reported	No details on number of contacts for index case
Kawasuji 2020	Nosocomial	105	Not reported	14/105 (1.33%)	
Khanh 2020	Community	217	Not reported	16/217 (7.4%)	
Kim 2020	Household	207	17.7 to 30	1/207 (0.5%)	
Kim 2020a	Household Community	4	18.7 to 32.1	N/A	
Kim 2020b	Nosocomial	3,091 respiratory samples from 2,924 individuals	Not reported	3/290 (1%)	
Kumar 2020	Community	822	Not reported	144/822 17.5%)	Spread of infection within the state was significantly higher from symptomatic cases, p=0.02
Kuwelker 2020	Household	179	N/A	45%	The elderly (>60 years old) had a significantly higher attack rate (72%) than adults< 60years old (46%, p=0·045)
Kwok 2020	Local Household	206	Not reported	24/206 (11.7%)	
Ladhani 2020	Nosocomial	254	Not reported	Unclear: 53/254 (21%) tested positive.	Staff working across different care homes (14/27, 52%) had a 3.0-fold (95% CI, 1.9–4.8; P<0.001) higher risk of SARS-CoV-2 positivity than staff working in single care homes (39/227, 17%).
Ladhani 2020a	Nosocomial	Residents: 264 Staff members: 254	Not specified	Unclear: 105/264 (53%) residents tested positive	Infectious virus recovery in asymptomatic staff and residents emphasises their likely importance as silent reservoirs and transmitters of infection and explains the failure of infection control measures which have been largely based on identification of symptomatic individuals.
Laws 2020	Household	188	Not reported	55/188 (29.3%)	
Laxminarayan 2020	Local Household Community	575,071	Not reported	10.7% (10.5 to 10.9%) for high-risk contacts 4.7% (4.6 to 4.8%) for low-risk contacts 79.3% (52.9 to 97.0%) for high-risk travel exposure	
Lee 2020	Household	12	Not reported	0/12 (0%)	
Lee 2020a	Household	23	Not reported	1/23 (4.4%)

Zhang 2020d	Local	8437	Not reported	25/8437 (0.3%)	
Zhuang 2020	Household Community	8363	Not reported	239/8363 (2.9%)	

(Basso 2020). The frequency of ARs in the remaining 21 studies ranged from 3.5 to 75% (Figure 3a). The ARs were highest in weddings (69%), prison (69.5%) and households (75%). Attack rates appeared lower in healthcare settings; two healthcare settings with higher ARs (Ladhani 2020, Ladhani 2020a) included nursing home residents – the definition of SARS-CoV-2 infection in both studies did not include the full constellation of respiratory and non-respiratory symptoms. In sports settings, the AR during matches was between 4.2% and 4.7%.

Twenty-nine studies reported data on ARs using serology (Table 6). The settings included educational (n=4), households (n=4) and healthcare (n=3). In eight studies, the frequency of attack was 0%. The frequency of attacks in the remaining 21 studies ranged from 0.7% to 75% (Figure 3b). The frequency of attacks was highest in households but lower in educational settings - especially daycare centres.

Frequency of SARS-CoV-2 secondary ARs

Overall, 126 studies (73.7%) reported data on secondary ARs (Table 6). The studies reported the rates based on RT-PCR tests, except for one study (Angulo-Bazán 2020) that used serology. In 16 of these studies, the SAR was 0%. The secondary ARs in the remaining 110 studies ranged from 0.3 to 100% (see Figure 4). The highest frequencies of secondary ARs (75–100%) occurred in household or quarantine settings; similar findings were observed when studies with higher reporting quality were examined (57–75%). In the three studies of index or primary cases with recurrent infections, there was no positive case amongst the 1518 close contacts across the studies.

Risk of infection

Forty-six studies (26.9%) reported results on the risk of infection (Table 7). One study of airline passengers (Khanh 2020) showed that seating proximity was significantly associated with the risk of contracting SARS-CoV-2 (RR 7.3, 95% CI 1.2–46.2); a second study (Speake 2020) reported that not sitting by the window was associated with a significantly increased risk of infection (RR 5.2; 95% CI 1.6–16.4; p<0.007)). The results of five studies (Chen 2020b, Doung-ngern 2020, Hobbs 2020, Wang 2020b, Wu 2020) showed that use of face covering during close contact with infected cases was associated with significantly lower risks of infection compared with no face covering; findings from one of these studies (Doung-ngern 2020) showed that wearing masks all the time during contact was not significantly different from wearing masks sometimes. The result of one study (Rosenberg 2020) showed that the incidence of infection significantly increased with age (p<0.0001), while those from another study (Poletti 2020) showed that being 70 years or older was associated with a significantly increased risk of SARS-CoV-2-related death (p<0.001), while another study (Zhang 2020a) reported that elderly close contacts (≥60 years) had a higher SAR compared with younger age groups. Findings from five studies (Bi 2020, Hu 2020a, Islam 2020, Luo 2020a, Wu 2020, Zhang 2020a) showed that household contact settings had significantly higher risks of infection compared with other types of contact settings, e.g., social, healthcare, workplace and public transport. One study (Lewis 2020) showed that the risk of infection was significantly increased amongst household contacts who were immunocompromised (OR 15.9, 95% CI 2.4–106.9). Finally, three studies

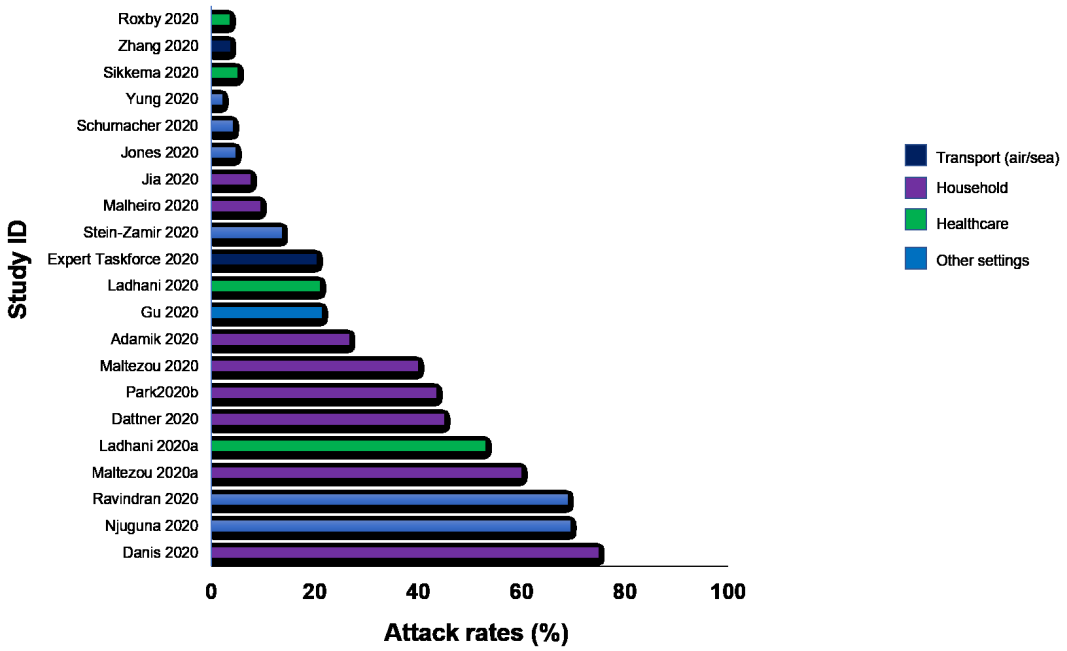

Figure 3a. Primary attack rates of SARS-CoV-2 in close contacts (PCR).

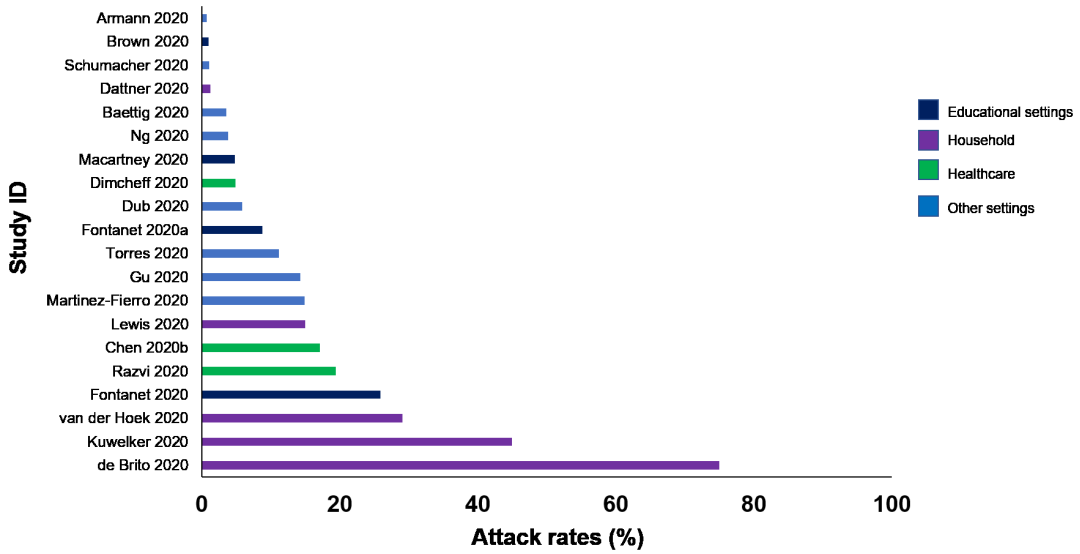

Figure 3b. **Primary attack rates of SARS-CoV-2 in close contacts (serology).**

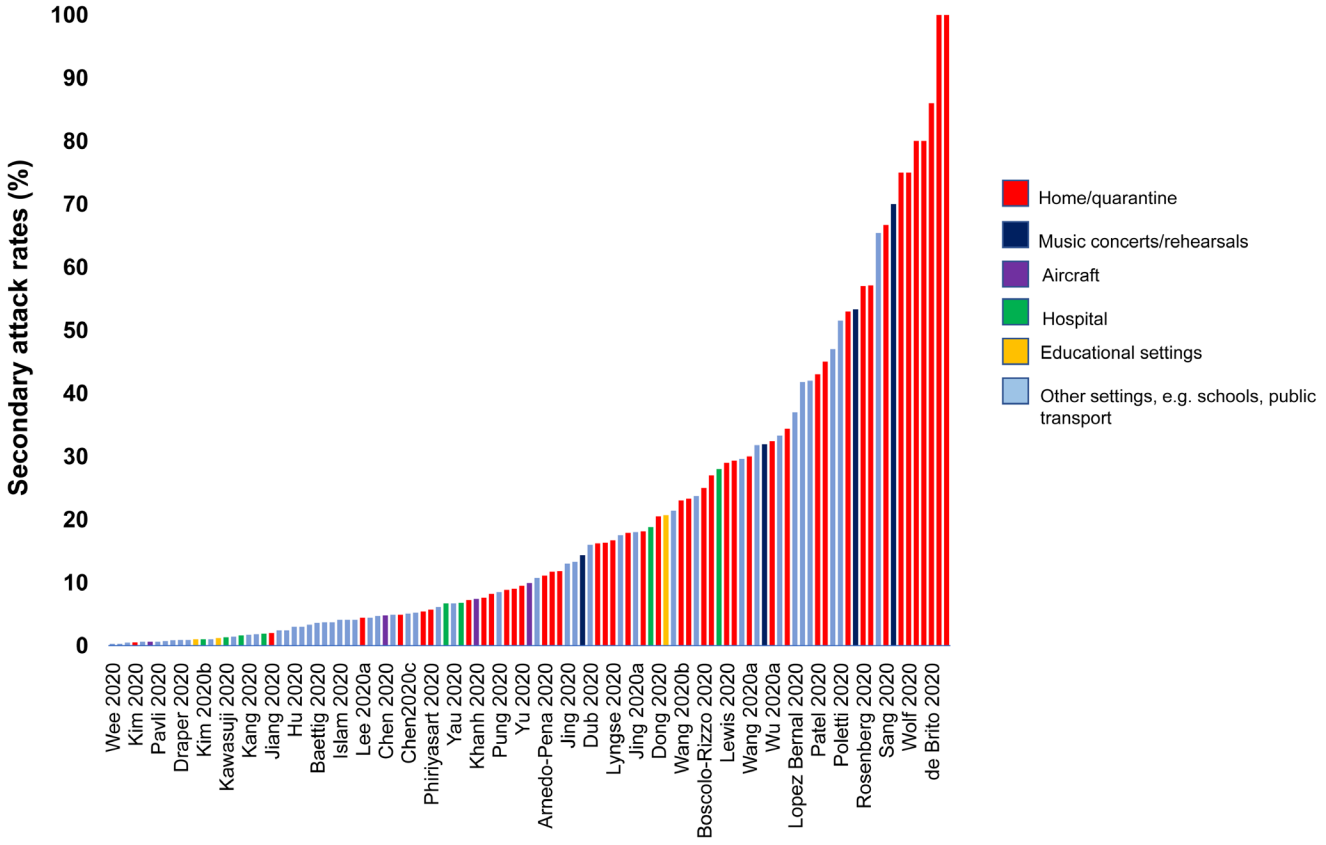

Figure 4. **Frequency of secondary attack rates of SARS-CoV-2 with Close Contacts.**

Table 7. Risk of infection in close contacts.

Study ID	Type of transmission	Risk of infection
Abdulrahman 2020	Community	**Eid Alfitr:** Pre-: 2990 (4.2%); Post-: 4987 (6.7%); p <0.001; **Ashura:** Pre-: 3571 (3.7%); Post-: 7803 (6.6%); p <0.001
Arnedo-Pena 2020	Household	The health profession of index case was a significant protective factor (p<0.007). Older age of secondary cases, two household members, and higher age of index case were significantly associated with elevated risk of infection: p<0.001 in each case
Bi 2020	Local Household Community	Household contact (OR 6·3; 95% CI 1·5–26·3) and travelling together (OR 7·1; 1·4–34·9) were significantly associated with infection. Reporting contact that occurred often was also associated with increased risk of infection compared with moderate-frequency contact (OR 8·8; 95% CI 2·6–30·1)
Chen 2020b	Nosocomial	In multivariate analysis, there existed higher risk of seroconversion for close contacts with patient 2 (OR, 6.605, 95% CI, 1.123, 38.830) and doctors exposed to their patient (OR, 346.837, 95% CI 8.924, 13479.434), while the lower risk of seroconversion was closely related to direct contact with COVID-19 patients wearing face mask (OR, 0.127, 95% CI 0.017, 0.968).
Chen 2020c	Local Community Household Nosocomial	Infection rate is highest when living with the case (13.26%), followed by taking the same means of transportation (11.91%). After removing the influence factors of the "super spreader" incident, the infection rate of vehicle contact dropped to 1.80%. The infection rate (7.18%) of entertainment activities such as gatherings, meeting guests, and playing cards was also relatively high, as was short-term face-to-face unprotected conversations or doing errands (6.02%). There was a statistically significant difference in the infection rate among the four categories of life contact, transportation contact, medical contact, and other contact (p<0.005). participation in Buddhist gatherings caused transmission. A total of 28 people were diagnosed as confirmed cases of new coronavirus pneumonia, 4 were asymptomatic infections, and the infection rate of close contacts reached 32.99% (32/97), which was much higher than the average infection rate (6.15). %), the difference is statistically significant (p<0.005).
Cheng 2020	Household Nosocomial	The overall secondary clinical attack rate was 0.7% (95% CI, 0.4%-1.0%). The attack rate was higher among the 1818 contacts whose exposure to index cases started within 5 days of symptom onset (1.0% [95% CI, 0.6%-1.6%]) compared with those who were exposed later (0 cases from 852 contacts; 95% CI, 0%-0.4%). The 299 contacts with exclusive presymptomatic exposures were also at risk (attack rate, 0.7% [95% CI, 0.2%-2.4%]). The attack rate was higher among household (4.6% [95% CI, 2.3%-9.3%]) and nonhousehold (5.3% [95% CI, 2.1%-12.8%]) family contacts than that in health care or other settings. The attack rates were higher among those aged 40 to 59 years (1.1% [95% CI, 0.6%-2.1%]) and those aged 60 years and older (0.9% [95% CI, 0.3%-2.6%]).
Chu 2020a	Household	Five (10%) of 48 secondary cases compared with 130 (33%) of 398 non-case household contacts reported potential community exposures: unadjusted OR 0.24 (95%CI 0.09 to 0.62), p=0.003
Dattner 2020	Household	PCR: 44% of adults were infected compared to 25% of the children (n=3353: 1809 children and 1544 adults) Serology: 34% of these children and 48% of the adults tested serologically positive (n=705: 417 children and 288 adults
Dimcheff 2020	Community Nosocomial Household	HCWs exposed to a known COVID-19 case outside work had a significantly higher seroprevalence at 14.8% (23 of 155) compared to those who did not 3.7% (48 of 1,296; OR, 4.53; 95% CI, 2.67–7.68; P < 0.0001)
Doung-ngern 2020	Local	Wearing masks all the time during contact was independently associated with lower risk of COVID-19 infection compared to not wearing masks (aOR 0.23, 95% CI 0.09–45 0.60), while wearing masks sometimes during contact was not (aOR 0.87, 95% CI 0.41–1.84). Maintaining at least 1m distance from a COVID patient (aOR 0.15, 95% CI 0.04–0.63) and duration of close contact ≤15 minutes versus longer (aOR 0.24, 95% CI 0.07–0.90) were significantly associated with lower risk of infection transmission

Study ID	Type of transmission	Risk of infection
Fateh-Moghadam 2020	Community	Workplace exposure was associated with higher risk of becoming a case than cohabi_x0019_ng with a case or having a non-cohabiting family member or friend who was a case. The greatest risk of transmission to contacts was found for the 14 cases <15 years of age (22.4%); 8 of the 14, who ranged in age from <1 to 11 years) infected 11 of 49 contacts.
Fontanet 2020a	Local	No significant difference in attack rates across primary school pupils, teachers, non-teaching staff, parents, and relatives, respectively (p=0.29).
Helsingen 2020	Local	11 individuals in the training arm (0.8% of those tested) and 27 in the non-training arm (2.4% of those those tested) tested positive for SARS-CoV-2 antibodies (p=0.001)
Hobbs 2020	Local Household Community	Case-patients were significantly more likely to have had close contact with a person with known COVID-19 than control participants (aOR = 3.2, 95% CI = 2.0–5.0) Case-patients were significantly more likely to have attended gatherings with persons outside their household, including social functions (aOR = 2.4, 95% CI = 1.1–5.5), activities with children (aOR = 3.3, 95% CI = 1.3–8.4), or to have had visitors at home (aOR = 1.9, 95% CI = 1.2–2.9) during the 14 days before the SARS-CoV-2 test. Parents of 64% of case-patients and 76% of control participants reported that their child and all staff members wore masks inside the facility (aOR = 0.4, 95% CI = 0.2–0.8).
Hu 2020	Household Community	Household contacts were associated with a significantly larger risk of SARS-CoV-2 infection than other types of contact (P<0.001). The transmission risk in the first generation was significantly higher than the later generations (p<0.001), possibly due to improved case isolation and contacts quarantine that deplete the number of susceptible individuals in the cluster.
Hua 2020	Household	Incidence of infection in child close contacts was significantly lower than that in adult contacts: 13.2% vs 21.2%, p=0.004
Islam 2020	Household Local Community Nosocomial	The secondary attack rate among household contacts was at the highest risk of attack (13.04%, 95% CI 9.67-16.41) followed by funeral ceremonies (8.33%, 95% CI 3.99-12.66) and family contacts (6.52%, 95% CI 4.02-9.02). The attack rate was higher in age groups 50–59 (10.89%, 95% CI 7.05-14.66) and 60–69 (9.09%, 95% CI 5.08-13.09)
Kawasuji 2020	Nosocomial	Among symptomatic patients (n =18), the estimated viral load at onset was higher in the index than in the non-index patients (median [95% confidence interval]: 6.6 [5.2–8.2] vs. 3.1 [1.5–4.8]. In adult (symptomatic and asymptomatic) patients (n = 21), median viral load at the initial sample collection was significantly higher in the index than in the non-index patients (p = 0.02)
Khanh 2020	Community	Seating proximity was strongly associated with increased infection risk (RR 7.3, 95% CI 1.2–46.2).
Laws 2020	Household	There were no significant differences in secondary infection rates between adult and pediatric contacts among all households (OR: 1.11; 95% CI: 0.56 to 2.21) or among households with children (OR: 0.99; 95% CI: 0.51 to 1.90).
Laxminarayan 2020	Local Household Community	Secondary attack rate estimates ranged from 1.2% (0.0 to 5.1%) in health care settings to 2.6% (1.6 to 3.9%) in the community and 9.0% (7.5 to 10.5%) in the household.
Lewis 2020	Household	Household contacts to COVID-19 patients with immunocompromised conditions and household contacts who themselves had diabetes mellitus had increased odds of infection with ORs 15.9 (95% CI, 2.4–106.9) and 7.1 (95% CI: 1.2–42.5). Household contacts of a male primary patient were more likely to have secondary infection than those of a female primary patient (SIR, 36% vs 18%; OR, 2.4; 95% CI, 1.1–5.3).

Study ID	Type of transmission	Risk of infection
Li 2020d	Household	The secondary attack rate to children (aged <18 years) was 4% compared with 20.5% for adult members (odds ratio [OR], .18; 95% confidence interval [CI], .06–.54; P = .002). The secondary attack rate to the contacts in the household with index patients quarantined at home immediately since onset of symptoms was 0% compared with 18.3% for the contacts in the households without index patients quarantined during the period between initiation of symptoms and hospitalization (OR, 0; 95% CI, .00–.00; p=0.000). The secondary transmission rate for individuals who were spouses of index cases was 27.8% compared with 17.3% for other members in the households (OR, 2.27; 95% CI, 1.22–4.22; p=0.010).
Liu 2020b	Household Community Nosocomial	Compared to young adults aged 20–29 years, the infected risk was higher in children (RR: 2.59, 95%CI: 1.79–3.76), and old people aged 60–69 years (RR: 5.29, 95%CI: 3.76–7.46). People having close relationship with index cases encountered higher infected risk (RR for spouse: 20.68, 95%CI: 14.28–29.95; RR for non-spouse family members: 9.55, 95%CI: 6.73–13.55; RR for close relatives: 5.90, 95%CI: 4.06–8.59). Moreover, contacts exposed to index case in symptomatic period (RR: 2.15, 95%CI: 1.67–2.79), with critically severe symptoms (RR: 1.61, 95%CI: 1.00–2.57)
Lopez Bernal 2020	Household Community	Secondary attack rates were highest where the primary case was aged <18 years with a significantly higher odds of secondary infection (OR 61, 95% CI 3.3-1133). Where the primary case was admitted to hospital there was a significantly lower odds of secondary infection in the household (OR 0.5, 95% CI 0.2-0.8). Secondary attack rates were lower in larger households.
Luo 2020a	Household Community Nosocomial	Household contacts had a significantly higher risk for secondary infection than did persons who were exposed in health care settings (OR, 0.09, 95%CI 0.04 to 0.20) or those who were exposed on public transportation (OR, 0.01, 95%CI, 0.00 to 0.08).
Macartney 2020	Local	The rate of staff member to child transmission was lower (1·5%) than staff to staff transmission (4·4%).
Malheiro 2020	Household	Among the intervention cohort,16 of 132 closecontacts tested positive during the follow-up period (attack rate:12.1%, 95% confidence interval [CI]: 7.1-18.9). In the control cohort,138 of 1495 participants tested positive (attack rate: 9.2%, 95% CI:7.8-10.8)
Park 2020a	Household Non-household	With index patients 30–39 years of age as reference, detection of COVID-19 contacts was significantly higher for index patients >40 years of age in nonhousehold settings.
Phiriyasart 2020	Household	Locally religious and household contacts of confirmed cases had significantly higher risks of SARS-CoV-2 infection than other community members.
Poletti 2020	Unclear	Individuals younger than 70 years were at a significantly lower risk of death after infection than older patients (p<0.001). The risk of death was 62% lower (95% CI: 31–80%; p<0.001) during the second phase of the epidemic.
Razvi 2020	Nosocomial	HCWs in patient facing roles had a significantly higher frequency of positive COVID-19 antibody tests (295/1302 [22.7%]) than those in non-patient facing roles (88/669 [13.2%]), p<0.0001)
Rosenberg 2020	Household	Prevalence significantly increased with age, ranging from 23% among those aged <5 years to 68% among those 65 years or older (p<0.0001)
Speake 2020	Aircraft	The risk for secondary infections among passengers seated in the mid cabin was significantly greater than for those seated in the aft cabin (p<0.005). The SAR among mid-cabin passengers in window seats was significantly greater than among those not in window seats (RR 5.2; 95% CI 1.6–16.4; p<0.007).
Sun 2020	Household	The family recurrence rate of spouses who introduced cases from the family was 63.87%, which was higher than the recurrence rate of children (30.53%), parents (28.37%) and other family members (20.93%), and the difference was statistically significant (P <0.001) .
Torres 2020	Community	Antibody positivity rates were 9.9% (95%CI: 8.2-11.8) for 1,009 students and 16.6% (95%CI: 12.1-21.9) for 235 staff. Among students, positivity was significantly associated with history of contact with a confirmed case (p<0.0001). The greater the number of contacts, the greater the probability that a child was antibody positive (p=0.05).

Study ID	Type of transmission	Risk of infection
van der Hoek 2020	Household	In families of a confirmed COVID-19 patient, children between 1 and 11 years were less often positive in PCR and serology than older children and adults.
Wang 2020b	Household	Face mask use by the primary case and family contacts before the primary case developed symptoms was 79% effective in reducing transmission (OR=0.21, 95% CI 0.06 to 0.79). Daily use of chlorine or ethanol based disinfectant in households was 77% effective (OR=0.23, 95% CI 0.07 to 0.84). Wearing a mask after illness onset of the primary case was not significantly protective. The risk of household transmission was 18 times higher with frequent daily close contact with the primary case (OR=18.26, 95% CI 3.93 to 84.79), and four times higher if the primary case had diarrhoea (OR=4.10, 95% CI 1.08 to 15.60). Household crowding was not significant.
Wood 2020	Household	Households without children had a significantly lower rate of COVID-19: HR per child 0.89; 95% CI 0.84–0.95. Households with childen had higher rates of COVID-19 tests (9.2% vs 6.1%) Compared to those in households without children, the risk of COVID-19 requiring hospitalisation was lower in those with one child and lower still in those with two or more children: HR 0.72 per child (95% CI 0.60-0.85, p<0.001); adjusted for age - HR 0.83 per child (95% CI 0.70-0.99)
Wu 2020	Household Local Community	Contacts living in the same household as the index case had significantly higher risk of infection vs those who had only had brief contact with the index case: RR 41.7 (17.7–98.5), p<0.001). Contacts who had visited, or had contact with the index case in a medical institution had significantly higher risk of acquiring infection vs brief contact with the index case: RR 3.6 (1.42–8.98), p=0.004. Family members who had contact with an index case had significantly higher risk of infection vs healthcare providers or other patients who had been exposed to an index case: RR 31.6 (7.69–130.01), p<0.001. Those who had contact with the index case through work, through study, or in a place of entertainment had a significantly higher risk of infection vs those who had contact with the index case in a medical institution: RR 6.7 (1.34–33.25), p=0.01. Those who had contact with the index case in or near his/her home had a significantly higher risk of infection vs those who had contact with the index case in a medical institution: RR 17.3 (4.20–70.77), p<0.001. The incidence rate among those who wore face masks was significantly lower than that among those who did not use protective measures (0.3% vs. 4.7%, respectively, p<0.001). The incidence rate of contacts with data collected by field investigation was significantly higher than that of contacts with data collected by big data (5.35% versus 0.07%, p<0.001).
Wu 2020a	Household	Contacts with >72 hours of exposure (SIR, 41.7%; [95% CI: 26.8%–58.3%]) had a higher SIR compared with those without (SIR, 23.2%; [95% CI: 11.4%–41.5%]). One household-level factor was significantly associated with SIR: household members without protective measures after illness onset of the index patient (odds ratio [OR], 4.43; [95% CI: 1.37–14.34]).
Xin 2020	Household	Increasing risk of infection among household contacts with female index patients (adjusted hazard ratio [aHR] = 3.84, 95% CI = 1.07–13.78), critical disease index patients (aHR = 7.58, 95% CI = 1.66–34.66), effective contact duration with index patients > 2 days (aHR = 4.21, 95% CI = 1.29–13.73), and effective contact duration > 11 days (aHR = 17.88, 95% CI = 3.26–98.01)
Yu 2020	Household	Family members, colleagues/classmates/travel companions, and doctors-patients accounted for 88.1% (1398), 10.7% (170), and 0.3% (5), respectively. Following this order, the infection rate was 10.2%, 1.8% and 40.0%, respectively.
Yung 2020	Household	Young children <5 years old were at lowest risk of infection (1.3%). Children were most likely to be infected if the household index case was the mother.
Zhang 2020a	Household Local Community	SAR among household contacts was 16.1% vs 1.1% for social contacts, and 0% for workplace contacts. Older close contacts had the highest SAR compared with other age groups; 8.0% in persons >60 years of age compared with 1.4%–5.6% in persons <60 years of age. Close contactsthat lived with an index case-patient had 12 times the risk for infection and those who had frequent contact with an index case-patient, >5 contacts during 2 days before the index case was confirmed, had 29 times the risk for infection.
Zhuang 2020	Household Community	The main sources of secondary infection were family exposure (74.5%, 178 cases), transportation exposure accounted for 8.4% (20 cases), friend/colleague meal exposure accounted for 5.9% (14 cases). Shopping malls, markets, pharmacies and other public place exposure accounted for 5.0% (12 cases), workplace exposure accounted for 3.8% (9 cases), and community exposure accounted for 2.5% (6 cases).

F1000Research 2021, 10:280 Last updated: 04 NOV 2022

(Bi 2020a, Wu 2020, Zhang 2020a) showed that the more frequent contacts with an index case was significantly associated with an increased risk of infection.

Viral culture

Three studies (Ladhani 2020a, Speake 2020, Yang 2020) performed viral culture (Table 8). All studies utilised Vero E6 cells for viral culture. In Ladhani 2020a (a study of elderly nursing home residents), positive samples with a Ct of <35 were incubated on Vero E6 cells and confirmed by cytopathic effect (CPE) up to 14 days post-inoculation. Positive culture results were obtained for symptomatic, post-symptomatic, pre-symptomatic and asymptomatic cases (21 residents and 12 staff); higher Ct values was significantly associated with decreasing ability to recover the virus ($p<0.001$). Among residents the virus was isolated 12 days before symptom onset and up to 13 days after and in staff up to 6 days before and 7 days after symptom onset. In Speake 2020, specimens were inoculated in Vero-E6 cells and inspected for CPE daily for up to 10 days with identity confirmed using "in-house" PCRs. The primary cases had boarded the flight from a cruise ship and had SARS-CoV-2 with the strain A2-Ruby Princess (A2-RP). Nine of 17 (53%) of PCR-positive samples grew SARS-CoV-2 in culture. Eight secondary cases who were in the same flight cabin with the infected travellers from the cruise ship all had viruses of the A2-RP strain (3 by full and 1 by partial sequence) (Table 8). In the third study of index patients with recurrent infection swab specimens were also inoculated on Vero cells, and monitored for CPE daily for 10 days (Yang 2020). All four viral cultures were negative (0%).

Genome sequencing (GS) and phylogenetic analysis

Ten studies (Böhmer 2020, Firestone 2020, Jiang 2020, Ladhani 2020a, Lucey 2020, Pung 2020, Sikkema 2020, Speake 2020, Taylor 2020, Wang 2020) performed GS and phylogenetic analysis (Table 9). The studies were primarily conducted in outbreak clusters and methods used for performing these investigations were essentially similar across the studies. The completeness of genomic similarity ranged from 81–100% across six studies (Firestone 2020, Jiang 2020, Lucey 2020, Sikkema 2020, Speake 2020, Wang 2020). Transmission from one case to a contact was demonstrated by non-synonymous nucleotide polymorphism in SARS-CoV-2 from these two cases onwards, but not in any cases detected prior to this instance (Böhmer 2020). In one study of skilled nursing home facilities (Taylor 2020), samples from 75 residents and five healthcare staff shared genetically related strains. In another study of care homes (Ladhani 2020a), reported nine separate introductions of SARS-CoV-2 into care homes by healthcare staff. In one study which used multiple settings (Pung 2020), the viral genomic sequences for four cases in one cluster shared identical sequences over the full genome length and shared a common base difference relative to the earlier sequences (see Table 8).

Discussion

Summary of main findings

We identified 171 primary studies assessing the role of close contact in transmission of SARS-CoV-2. The evidence from these observational studies suggest that the risk of transmission is significantly increased through close contact with an infected case - the greater the frequency of contact, the greater the risk. Household contact setting is significantly more likely to result in transmission of SARS-CoV-2 compared to other types of contact settings. This risk of transmission appears to decrease with use of face masks and in cases where the index or primary cases are in the paediatric age group. The risk of close contact transmission is significantly increased in the elderly. Enclosed environments and social gatherings appear to increase the likelihood of close contact transmission. Close contact with persons having recurrent infection with SARS-CoV-2 is unlikely to result in transmission of the virus. There is wide heterogeneity in study designs and methods and the overall quality of evidence from published primary studies is sub-optimal. The results of systematic reviews also suggest that household contact setting increases the risk of transmission and being elderly is also associated with increased risks of transmission and mortality.

The positive results of viral cultures observed in two studies support the results of PCR and serologic tests showing that close contact setting was associated with transmission of SARS-CoV-2. The failure to successfully isolate the virus in the third study supports the view that individuals who are re-infected are unlikely to transmit the virus in close contact settings. The positive findings from all 10 studies that performed GS and phylogenetic analysis with identical strains supports the hypothesis that close contact setting is associated with SARS-CoV-2 transmission through respiratory droplets or direct contact. The failure of the majority of studies to report Ct values casts doubts on the strengths of any reported associations because of the likelihood of false positives, as is the lack of (and variation in) reporting of the timelines for sample collections. The variations observed in the definitions of close contacts also cast further doubts on the validity of overall results.

Comparison with the existing literature

The results of our review are consistent with several guidelines suggesting that close contact with index cases can result in transmission of SARS-CoV-2[8–10]. Our findings are also consistent with those of a systematic review which concluded that face masks are effective for preventing transmission of respiratory viruses[11]. The results of our review also support those of a previous review which showed that the elderly are at increased risk of infection and mortality with coronavirus[12]. However, our review contains a greater number of studies compared to each of the included individual reviews and shows evidence demonstrating positive culture of virus as well as genomic evidence of close contact transmission. This differs from the findings from our reviews of fomite, orofecal and airborne transmission that failed to show evidence of either positive culture or genomic sequences demonstrating SARS-CoV-2 transmission[13–15].

Strengths and limitations

To our knowledge, this is the most comprehensive review to date investigating the role of close contact in the transmission of SARS-CoV-2. We extensively searched the literature for eligible studies, accounted for the quality of included studies and have reported outcomes (viral culture and GS) that

Table 8. Results of viral cultures.

Study ID	Types of participants	Method used for viral culture	Results of viral culture
Ladhani 2020a	Staff and residents of 6 London care homes	All SARS-CoV-2 positive samples with a Ct value of >35 were incubated on Vero E6 mammalian cells and virus detection was confirmed by cytopathic effect (CPE) up to 14 days post-inoculation	87 samples with Ct values <35 were cultured and infectious virus was recovered from all (21 residents and 12 staff). Live virus was isolated up to 13 days after and 12 days before symptom onset among residents and up to 6 days before and 7 days after symptom onset among staff. Higher Ct values was significantly associated with decreasing ability to recover infectious virus (p<0.001). There were no significant differences in virus recovery rates between symptomatic and asymptomatic residents (5/17 [29.4%] vs. 14/33 [42.4%]; P = 0.37) and staff (2/6 [33.3%] vs. 10/31 [32.3%]; P = 0.96) at the time of testing.
Speake 2020	241 airline passengers some of whom had disembarked from 1 of 3 cruise ships that had recently docked in Sydney Harbour. 6 primary cases initially	Virus culture was attempted for primary samples .Clinical specimens were inoculated in triplicate wells with Vero-E6 cells at 80% confluency, incubated at 37°C in 5% CO2, and inspected for cytopathic effect daily for up to 10 days. Identity was confirmed by in-house PCRs as described for previous sequences.	9/17 of PCR positive samples grew SARS-CoV-2 on viral culture. Sufficient viral RNA was available to generate an adequate sequence for 25 of the 29 samples positive by PCR. 11 passengers had PCR-confirmed SARS-CoV-2 infection and symptom onset within 48 hours of the flight. All 11 passengers had been in the same cabin with symptomatic persons who had culture-positive A2-RP virus strain.
Yang 2020	Home quarantine: 93 recurrent-positive patients; 96 close contacts and 1,200 candidate contacts	Vero-E6 cells were used for virus isolation in a BSL-3 laboratory.	Viral culture of 4 specimens with Ct <30 were negative

Table 9. GS and phylogenetic analysis.

Study ID	Study Setting	Method used for WGS	Phylogenetic analysis	Results
Böhmer 2020	Home, workplace	Whole genome sequencing involved Roche KAPA HyperPlus library preparation and sequencing on Illumina NextSeq and MiSeq instruments as well as RT-PCR product sequencing on Oxford Nanopore MinION using the primers described in Corman and colleagues. Patient 1 was sequenced on all three platforms; patients 2–7 were sequenced on Illumina NextSeq, both with and without RT-PCR product sequencing with primers as in Corman and colleagues; and patients 8–11, 14, and 16 were sequenced on Oxford Nanopore MinION. Sequencing of patient 15 was not successful. Sequence gaps were filled by Sanger sequencing.	Not reported	Presymptomatic transmission from patient 4 to patient 5 was strongly supported by virus sequence analysis: a nonsynonymous nucleotide polymorphism (a G6446A substitution) was found in the virus from patients 4 and 5 onwards but not in any cases detected before this point (patients 1–3). Later cases with available specimens, all containing this same substitution, were all traced back to patient 5. The possibility that patient 4 could have been infected by patient 5 was excluded by detailed sequence analysis: patient 4 had the novel G6446A virus detected in a throat swab and the original 6446G virus detected in her sputum, whereas patient 5 had a homogeneous virus population containing the novel G6446A substitution in the throat swab.
Firestone 2020	Motorcycle rally	WGS was conducted at the MDH Public Health Laboratory on 38 specimens using previously described methods.	Phylogenetic relationships, including distinct clustering of viral whole genome sequences, were inferred based on nucleotide differences via IQ-TREE using general time reversible substitution models as a part of the Nextstrain workflow.	38 (73%) specimens (23 [61%] from primary and 15 [39%] from secondary and tertiary cases) were successfully sequenced, covering at least 98% of the SARS-CoV-2 genome. Six genetically similar clusters with known epidemiologic links were identified (i.e., cases in patients who were close contacts or who had common exposures at the rally), five of which demonstrated secondary or secondary and tertiary transmission.
Jiang 2020	Home	Positive samples were sequenced directly from the original specimens as previously described. *Reference virus genomes were obtained from GenBank using Blastn with 2019-nCoV as a query. The open reading frames of the verified genome sequences were predicted using Geneious (version 11.1.5) and annotated using the Conserved Domain Database. Pairwise sequence identities were also calculated using Geneious. Potential genetic recombination was investigated using SimPlot software and phylogenetic analysis.	The maximum likelihood phylogenetic tree of the complete genomes was conducted by using RAxML software with 1000 bootstrap replicates, employing the general time-reversible nucleotide substitution model.	The full genome of 8 patients were >99.9% identical across the whole genome. Phylogenetic analysis showed that viruses from patients were clustered in the same clade and genetically similar to other SARS-CoV-2 sequences reported in other countries.

Study ID	Study Setting	Method used for WGS	Phylogenetic analysis	Results
Ladhani 2020a	Care homes	Whole genome sequencing (WGS) was performed on all RT-PCR positive samples. Viral amplicons were sequenced using Illumina library preparation kits (Nextera) and sequenced on Illumina short-read sequencing machines. Raw sequence data was trimmed and aligned against a SARS-CoV-2 reference genome (NC_045512.2). A consensus sequence representing each genome base was derived from the reference alignment.	Consensus sequences were assessed for quality, aligned using MAFFT (Multiple Alignment using Fast Fourier Transform, version 7.310), manually curated and maximum likelihood phylogenetic trees derived using IQtree (version 2.04).	All 158 PCR positive samples underwent WGS analysis and 99 (68 residents, 31 staff) distributed across all the care homes yielded sequence sufficient for WGS analysis. Phylogenetic analysis identified informal clusters, with evidence for multiple introductions of the virus into care home settings. All care home clusters of SARS-CoV-2 genomes included at least one staff member, apart from care home B with no PCR positive staff and high rates of staff self-isolation. Care home A exhibited three distinct sequence clusters and six singletons, potentially representing up to nine separate introductions. Genomic analysis did not identify any differences between asymptomatic/symptomatic residents/staff. The 10 sequences from residents who died were distributed across the lineages identified and were closely matched to sequences derived from non-fatal cases in the same care homes.
Lucey 2020	Hospital	Complementary DNA was obtained from isolated RNA through reverse transcription and multiplex PCR according to the protocol provided by the Artic Network initiative. Libraries were prepared using the NEBNext Ultra II kit (New England Biolabs) and sequenced on an Illumina MiSeq using 300-cycle v2 reagent kits (Illumina). Bowtie 2 was used for aligning the sequencing reads to the reference genome for SARS-CoV-2 (GenBank number, MN908947.3) and SAMtools for manipulating the alignments.	SNPs were used to define clusters and a median-joining network was generated including these data from this study and an additional 1,000 strains collected from GISAID available on May 22nd. Clade annotation was included for the Pangolin, GISAID and NextStrain systems.	WvGS identified six clusters of nosocomial SARS-CoV-2 transmission. The average sequence quality per samples was > 99% for 46 samples, and between 92 and 94% for 4 samples. Phylogenetic analysis identified six independent groups of which clusters 1–3 were related to 39 patients.
Pung 2020	Multiple: Company conference, church, tour group.	Strain names, GISAID EpiCoV accession numbers used for genomic sequencing	Phylogenetic tree utilised the Neighbor-Joining method and confirmed using Maximum Likelihood approaches. Replicate trees with bootstrap used. All ambiguous positions were removed for each sequence pair (pairwise deletion option). Evolutionary analyses were conducted in MEGA X. Strain names, GISAID EpiCoV accession numbers and collection dates are shown, followed by the case number if available.	Cluster A: Viral genomic sequences were available for four cases (AH1, AH2, AH3, and AT1) and phylogenetic analysis confirmed their linkage, as suggested by the epidemiological data.

Study ID	Study Setting	Method used for WGS	Phylogenetic analysis	Results
Sikkema 2020	Hospital	Samples were selected based on a Ct <32. A SARS-CoV-2-specific multiplex PCR for nanopore sequencing was done. The resulting raw sequence data were demultiplexed using qcat. Primers were trimmed using cutadapt,17 after which a reference-based alignment to the GISAID (Global Initiative on Sharing All Influenza Data) sequence EPI_ISL_412973 was done using minimap2. The consensus genome was extracted and positions with a coverage less than 30 reads were replaced with N using a custom script using biopython software (version 1.74) and the python module pysam (version 0.15.3). Mutations in the genome were confirmed by manually checking the alignment, and homopolymeric regions were manually checked and resolved, consulting the reference genome. Genomes were included when having greater than 90% genome coverage. All available full-length SARS-CoV-2 genomes were retrieved from GISAID20 on March 20, 2020 (appendix 1 pp 8–65), and aligned with the newly obtained SARS-CoV-2 sequences in this study using the multiple sequence alignment software MUSCLE (version 3.8.1551). Sequences with more than 10% of N position replacements were excluded. The alignment was manually checked for discrepancies, after which the phylogenomic software IQ-TREE (version 1.6.8) was used to do a maximum-likelihood phylogenetic analysis, with the generalised time reversible substitution model GTR+F+I+G4 as best predicted model. The ultrafast bootstrap option was used with 1000 replicates. Clusters were ascertained based on visual clustering and lineage designations.	The code to generate the minimum spanning phylogenetic tree was written in the R programming language. Ape24 and igraph software packages were used to write the code to generate the minimum spanning tree, and the visNetwork software package was used to generate the visualisation. Pairwise sequence distance (used to generate the network) was calculated by adding up the absolute nucleotide distance and indel-block distance. Unambiguous positions were dealt with in a pairwise manner. Sequences that were mistakenly identified as identical, because of transient connections with sequences containing missing data, were resolved.	46 (92%) of 50 sequences from health-care workers in the study were grouped in three clusters. Ten (100%) of 10 sequences from patients in the study grouped into the same three clusters:

Study ID	Study Setting	Method used for WGS	Phylogenetic analysis	Results
Speake 2020	Aircraft	Processed reads were mapped to the SARS-CoV-2 reference genome (GenBank accession no. MN908947). Primer-clipped alignment files were imported into Geneious Prime version 2020.1.1 for coverage analysis before consensus calling, and consensus sequences were generated by using iVar version 1.2.2.	Genome sequences of SARS-CoV-2 from Western Australia were assigned to lineages by using the Phylogenetic Assignment of Named Global Outbreak LINeages (PANGOLIN) tool (https://github.com/cov-lineages/pangolinExternal Link). On July 17, 2020, we retrieved SARS-CoV-2 complete genomes with corresponding metadata from the GISAID database. The final dataset contained 540 GISAID whole-genome sequences that were aligned with the sequences from Western Australia generated in this study by using MAFFT version 7.467. Phylogenetic trees were visualized in iTOL (Interactive Tree Of Life, https://itol.embl.deExternal Link) and MEGA version 7.014.	100% coverage was obtained for 21 and partial coverage (81%–99%) for 4 samples. The phylogenetic tree for the 21 complete genomes belonged to either the A.2 (n = 17) or B.1 (n = 4) sublineages of SARS-CoV-2
Taylor 2020	Skilled nursing facilities	WGS was conducted by MDH-PHL on available specimens using previously described methods.	Phylogenetic relationships, including distinct clustering of viral whole genome sequences, were inferred based on nucleotide differences via IQ-TREE, using general time reversible substitution models	Specimens from 18 (35%) residents and seven (18%) HCP at facility A were sequenced - Strains from 17 residents and five HCP were genetically similar. At facility B, 75 (66%) resident specimens and five (7%) HCP specimens were sequenced, all of which were genetically similar.
Wang 2020	Home	Full genomes were sequenced using the BioelectronSeq 4000. WGS integrated information from 60 published genomic sequences of SARS-CoV-2. Full-length genomes were combined with published SARS-CoV-2 genomes and other coronaviruses and aligned using the FFT-NS-2 model by MAFFT.	Maximum-likelihood phylogenies were inferred under a generalised-time-reversal (GTR)+ gamma substitution model and bootstrapped 1000 times to assess confidence using RAxML.	The phylogenetic tree of full-length genomes showed that SARS-CoV-2 strains form a monophyletic clade with a bootstrap support of 100%. Sequences from six HCWs in the Department of Neurosurgery and one family member were closely related in the phylogenetic tree. 33 family members of the HCWs were not secondarily infected, due to the strict self-quarantine strategies taken by the HCWs immediately after their onset of illness, including wearing a facial mask when they came home, living alone in a separated room, never eating together with their families.

were previously unreported in previous reviews. However, we recognize some limitations. We may not have identified all relevant studies examining the role of close contact in transmission - this is especially true for unpublished studies. We included results from non-peer reviewed studies which may affect the reliability of the review results. However, such studies could potentially be of research benefit because of the ongoing pandemic; in addition, we performed forward citation search of relevant studies.

Implications for research

Future studies should endeavour to include Ct values (or preferably convert the Ct values to number of genome copies using standard curves) when reporting research results and should describe the timing and methods of sample collection. Details surrounding the proximity, timing, and activities within the context of close contact need to be described. In studies of elderly subjects, more detailed description of baseline demographics should be reported. Further studies showing virus isolation in close contact settings should be conducted to strengthen the current evidence base; this could include performing serial cultures. Similarly, more research examining genomic sequences and phylogenetic trees in suspected close contact transmissions should be conducted - this should also extend to research examining other modes of transmission. The variation in methods and thresholds of the serological tests add to the confusion about diagnostic accuracy of testing; indeed, some authors have questioned the value of serological tests for diagnosing SARS-CoV-2[16]. To overcome the challenge of interpreting antibody responses, guidelines for better reporting of serological tests and results should be developed; this has previously been emphasized by other authors. Internationally recognized research dictionary of terms defining and describing close contact settings should be developed. Standardized guidelines for reporting research results should be a priority. Local, national, and international health organisations should promote good hygiene measures including advising against close contact with SARS-CoV-2 infected individuals; use of medical masks should be encouraged in circumstances where close contact with infected cases is likely. Activities in enclosed settings should be discouraged and social distancing in close contact settings should be encouraged.

Conclusion

The evidence from published observational studies and systematic reviews indicate that SARS-CoV-2 can be transmitted via close contact settings. Household contact and increased frequency of contact with infected cases significantly increase the risk of transmission. The quality of evidence from published studies is low-to moderate. Variations in study designs and methodology restrict the comparability of findings across studies. Standardized guidelines for the reporting of future research should be developed.

Data availability

Underlying data

All data underlying the results are available as part of the article and no additional source data are required.

Richard Wamai
Integrated Initiative for Global Health, Northeastern University, Boston, MA, USA

I have read this manuscript with keen interest and over several weeks during which COVID-19 has continued to evolve with new studies coming out and policy changes across countries I have been traveling in (Kenya and US). This manuscript deals with the question of availability of evidence for role of close contact in COVID-19 transmission. This question seems obvious now given 2+ years of generalized policy around the world for physical or social distancing. A lay observation would be to say that there is unequivocal evidence that close proximity has a role in the transmission of COVID (after all we have been told to distance). The authors of the present manuscript deal with the question of availability of scientific evidence for this generalized policy.

Clearly, a lot (if not all) of the NPIs (non-pharmaceutical interventions) have been implemented without evidence whether they work (Halperin DT, Hearst N, Hodgins S, *et al.* (2021)[1] - I am a co-author in this study. The current manuscript shows just how murky the state of evidence of these NPIs is. Consider the state of evidence of mask-wearing; just the Bangladeshi study is the only RCT we have, and the evidence that masks work from this trial is not that great (Abaluck J, Kwong LH, Styczynski A, *et al.,* 2022[2])

In my view, assessment of the merits of this manuscript should center on two things. The first is whether the authors have identified all the evidence available as published in scientific literature. The second is whether the authors make good-faith representation of the studies they have reviewed. I say “good-faith” because there are questions raised by the existing reviews and comments of this manuscript. Additionally, “good-faith” means to me that the authors have not omitted results from the studies. On these two accounts I write my recommendation. A systematic/scoping review is a unique type of study because authors should be presenting in good faith the information from the studies reviewed.

1. Have the authors examined all of the available evidence (=published studies) on the question?

The authors both say they have and have documented and included the method of their search

for the literature reviewed (Appendix 2). The only problem I see with this is that studies reviewed were only those published as of December 20, 2020. That was the first full year of the pandemic. Publications from 2021 are not included. One would presume that it is more likely that more studies on the effect of distancing could have been conducted in 2021. Those studies are not included in this manuscript, and that is a shortcoming. One – and at the minimum necessary – revision that could be made is to add the timeframe of the review in the Title of the manuscript. In my view, it is not necessary for the authors to begin including the studies from 2021 as that would require a full new search and a re-write of large potions of the manuscript.

2. Have the authors presented truthfully and good-faith the evidence from the studies?

This is the central question for this manuscript, and it appears more so the case given the extensive comments by the readers. In my view, all of the criticism is not warranted. Criticism is due where the authors have not presented results from the studies reviewed truthfully and in good-faith. Criticism is also due where gaps in evidence is not acknowledged or are pertaining. I do not think the readers present counter evidence, i.e., show that the authors have summarized results from a specific study or set of studies erroneously. In the same vein I am not convinced that readers demonstrate that the authors have misinterpreted results from the studies they have reviewed; such misinterpretation would be strong grounds for Not Approving this manuscript or calling for its revisions, of course. If the readers are presenting evidence to counter the evidence from the studies presented by the authors from other studies that is acceptable. But that should also be weighed against my point 1 above. For instance, could the initial search have missed such studies raised by the readers?

Also, I would not engage in some of the debates presented. For instance, I do not think the manuscript should be criticized because *"these authors may lack key expertise in their team"*. I have read through the contributors' listed expertise. I do not think any special expertise above and beyond what the author team has is needed to conduct a systematic review or truthfully and in good-faith summarize the evidence from the reviewed studies. In addition, I do not think that simply because persons in the author team are members of a decision-making body like the WHO that disqualifies them from objectivity or removes their training in science and scholarship. On the contrary, I think there is great value when decision-makers also participate in science. The obvious problem, of course, is where there are conflicts of interests, or where such persons are compromised. However, we have to take the consideration that in a multi-authored manuscript not one of the authors influences the entire narrative of the manuscript or results presented. Persons whose employment or affiliation positions may – or may be perceived to – compromise any perspectives presented in a manuscript they have co-authored should of course declare the conflicts of interests. Declaration of conflicts of interests is a standard protocol required in journal standards.

Having said the above, I have a few other observations or questions of my own.

Q1: On table 5, many studies are of no assessed quality, i.e., miss the quality measures specified in this table. What if studies missing all (or even just 2) of these measures are excluded in the analysis? So, if only those applicable as judged in Fig 2 are included.

Q2: On page 46, "Risk of Infection". Is not 'risk of infection' similar to AR (attack rate) in the sense that AR reports risk of infection? In this section too (with Fig 3a) we would expect AR and SAR

results to indicate risk of infection. Where, correspondingly, ARs and SARs are higher than risk of infection is high. Thus, risk of infection analysis do not present different results. Is this not how this should be understood?

Q3: "Implications for Research", page 58. The text, *"Local, national, and international health organisations should promote good hygiene measures including advising against close contact with SARS-CoV-2 infected individuals; use of medical masks should be encouraged in circumstances where close contact with infected cases is likely. Activities in enclosed settings should be discouraged and social distancing in close contact settings should be encouraged."* - To me, and objectively assessing the timing of the pandemic where we are today (April 1st 2022), this text is mostly 'water under the bridge' and should thus be updated – if this manuscript is to be indexed. See discussions, e.g., in Halperin DT, Hearst N, Hodgins S, *et al.* (2021)[1].

Additionally, I am not convinced the authors have presented compelling evidence here to warrant prompting such measures this text I highlight here include. The authors should strictly adhere to the evidence of their manuscript; it is wrong for the authors to echo the chorus of songs we have heard about these NPIs when there is no or limited evidence they work. Thirdly, as a further reason to exclude this concluding text, in this manuscript there is no discussion about hygiene. Evidence presented does not show close contact be avoided whatever the case. For instance, relevant studies reviewed show no transmission from (index) persons with previous repeated infection. Given this and the fact that by now many (if not most) people will have been infected (i.e., generalized spread) even multiple times (e.g., CDC. Nov. 16, 2021. Estimated COVID-19 Burden, https://www.cdc.gov/coronavirus/2019-ncov/cases-updates/burden.html), should we still be advocating for quarantine and masking? We argue for adherence to evidence (Halperin DT, Hearst N, Hodgins S, *et al*., 2021[1].

Finally, there will be a few grammatical errors that should be checked.

I am grateful for the opportunity to read this manuscript and share my observations which I hope will help guide the authors in determining merit worthiness for indexing as well as contribute to continued discussions.

Are the rationale for, and objectives of, the Systematic Review clearly stated?

Yes

Are sufficient details of the methods and analysis provided to allow replication by others?

Yes

Is the statistical analysis and its interpretation appropriate?

Not applicable

Are the conclusions drawn adequately supported by the results presented in the review?
Yes

Competing Interests: No competing interests were disclosed.

Reviewer Expertise: Global public health

I confirm that I have read this submission and believe that I have an appropriate level of expertise to confirm that it is of an acceptable scientific standard, however I have significant reservations, as outlined above.

Author Response 29 Jun 2022

IGHO ONAKPOYA, University of Oxford, Oxford, UK

Peer reviewer's comment: I have read this manuscript with keen interest and over several weeks during which COVID-19 has continued to evolve with new studies coming out and policy changes across countries I have been traveling in (Kenya and US). This manuscript deals with the question of availability of evidence for role of close contact in COVID-19 transmission. This question seems obvious now given 2+ years of generalized policy around the world for physical or social distancing. A lay observation would be to say that there is unequivocal evidence that close proximity has a role in the transmission of COVID (after all we have been told to distance). The authors of the present manuscript deal with the question of availability of scientific evidence for this generalized policy.
Authors' response: Thank you.

Peer reviewer's comment: Clearly, a lot (if not all) of the NPIs (non-pharmaceutical interventions) have been implemented without evidence whether they work (Halperin DT, Hearst N, Hodgins S, *et al.* (2021)1 - I am a co-author in this study. The current manuscript shows just how murky the state of evidence of these NPIs is. Consider the state of evidence of mask-wearing; just the Bangladeshi study is the only RCT we have, and the evidence that masks work from this trial is not that great (Abaluck J, Kwong LH, Styczynski A, *et al.,* 20222)
Authors' response: Thank you for this observation. As at the time we conducted the initial review, the evidence base was poor.

Peer reviewer's comment: In my view, assessment of the merits of this manuscript should center on two things. The first is whether the authors have identified all the evidence available as published in scientific literature. The second is whether the authors make good-faith representation of the studies they have reviewed. I say “good-faith” because there are questions raised by the existing reviews and comments of this manuscript. Additionally, “good-faith” means to me that the authors have not omitted results from the studies. On these two accounts I write my recommendation. A systematic/scoping review is a unique type of study because authors should be presenting in good faith the information from the studies reviewed.
Authors' response: Thank you for focusing your peer review on the evidence as presented in the manuscript.

Peer reviewer's comment: 1. Have the authors examined all of the available evidence

(=published studies) on the question?
The authors both say they have and have documented and included the method of their search for the literature reviewed (Appendix 2). The only problem I see with this is that studies reviewed were only those published as of December 20, 2020. That was the first full year of the pandemic. Publications from 2021 are not included. One would presume that it is more likely that more studies on the effect of distancing could have been conducted in 2021. Those studies are not included in this manuscript, and that is a shortcoming. One – and at the minimum necessary – revision that could be made is to add the timeframe of the review in the Title of the manuscript. In my view, it is not necessary for the authors to begin including the studies from 2021 as that would require a full new search and a re-write of large potions of the manuscript.
Authors' response: We have updated the electronic searches up till 30/04/2022 because of the comments from reviewer #1 and re-written several aspects of the manuscript to reflect this update.

Peer reviewer's comment: 2. Have the authors presented truthfully and good-faith the evidence from the studies?
This is the central question for this manuscript, and it appears more so the case given the extensive comments by the readers. In my view, all of the criticism is not warranted. Criticism is due where the authors have not presented results from the studies reviewed truthfully and in good-faith. Criticism is also due where gaps in evidence is not acknowledged or are pertaining. I do not think the readers present counter evidence, i.e., show that the authors have summarized results from a specific study or set of studies erroneously. In the same vein I am not convinced that readers demonstrate that the authors have misinterpreted results from the studies they have reviewed; such misinterpretation would be strong grounds for Not Approving this manuscript or calling for its revisions, of course. If the readers are presenting evidence to counter the evidence from the studies presented by the authors from other studies that is acceptable. But that should also be weighed against my point 1 above. For instance, could the initial search have missed such studies raised by the readers?
Authors' response: We thank the reviewer for making this point. We agree with you that the criticisms were not justified. We searched, identified, and analyzed the available evidence at that time point.

Peer reviewer's comment: Also, I would not engage in some of the debates presented. For instance, I do not think the manuscript should be criticized because *"these authors may lack key expertise in their team"*. I have read through the contributors' listed expertise. I do not think any special expertise above and beyond what the author team has is needed to conduct a systematic review or truthfully and in good-faith summarize the evidence from the reviewed studies. In addition, I do not think that simply because persons in the author team are members of a decision-making body like the WHO that disqualifies them from objectivity or removes their training in science and scholarship. On the contrary, I think there is great value when decision-makers also participate in science. The obvious problem, of course, is where there are conflicts of interests, or where such persons are compromised. However, we have to take the consideration that in a multi-authored manuscript not one of the authors influences the entire narrative of the manuscript or results presented. Persons whose employment or affiliation positions may – or may be perceived to – compromise any

perspectives presented in a manuscript they have co-authored should of course declare the conflicts of interests. Declaration of conflicts of interests is a standard protocol required in journal standards.
Authors' response: Again, we agree with the reviewer. We have enough expertise in our team and have co-authored hundreds of systematic reviews.

Peer reviewer's comment: Having said the above, I have a few other observations or questions of my own.
Authors' response: Thank you. We have responded to each observation.

Peer reviewer's comment: Q1: On table 5, many studies are of no assessed quality, i.e., miss the quality measures specified in this table. What if studies missing all (or even just 2) of these measures are excluded in the analysis? So, if only those applicable as judged in Fig 2 are included.
Authors' response: If we removed studies missing all or even 2 domains, we think the overall quality would still be low to moderate. Only 9 studies adequately dealt with bias.

Peer reviewer's comment: Q2: On page 46, "Risk of Infection". Is not 'risk of infection' similar to AR (attack rate) in the sense that AR reports risk of infection? In this section too (with Fig 3a) we would expect AR and SAR results to indicate risk of infection. Where, correspondingly, ARs and SARs are higher than risk of infection is high. Thus, risk of infection analysis do not present different results. Is this not how this should be understood?
Authors' response: The AR is a crude measure of the rate of infection in a group. The risk of infection compares the rate of attacks between or across groups, based on other variables, e.g., seating proximity. (See Box 1).

Peer reviewer's comment: Q3: "Implications for Research", page 58. The text, *"Local, national, and international health organisations should promote good hygiene measures including advising against close contact with SARS-CoV-2 infected individuals; use of medical masks should be encouraged in circumstances where close contact with infected cases is likely. Activities in enclosed settings should be discouraged and social distancing in close contact settings should be encouraged."* - To me, and objectively assessing the timing of the pandemic where we are today (April 1st 2022), this text is mostly 'water under the bridge' and should thus be updated – if this manuscript is to be indexed. See discussions, e.g., in Halperin DT, Hearst N, Hodgins S, *et al.* (2021)1.
Authors' response: We understand the point the reviewer makes. These statements were based on our understanding at that time. We have revised this section with the updated evidence. We have included the suggested reference.

Peer reviewer's comment: Additionally, I am not convinced the authors have presented compelling evidence here to warrant prompting such measures this text I highlight here include. The authors should strictly adhere to the evidence of their manuscript; it is wrong for the authors to echo the chorus of songs we have heard about these NPIs when there is no or limited evidence they work. Thirdly, as a further reason to exclude this concluding text, in this manuscript there is no discussion about hygiene. Evidence presented does not show close contact be avoided whatever the case. For instance, relevant studies reviewed

show no transmission from (index) persons with previous repeated infection. Given this and the fact that by now many (if not most) people will have been infected (i.e., generalized spread) even multiple times (e.g., CDC. Nov. 16, 2021. Estimated COVID-19 Burden, https://www.cdc.gov/coronavirus/2019-ncov/cases-updates/burden.html), should we still be advocating for quarantine and masking? We argue for adherence to evidence (Halperin DT, Hearst N, Hodgins S, *et al*., 2021[1].
Authors' response: Thank you for raising this issue and we agree that we should stay focused on the evidence found in our review. We have accordingly revised the text as above.

Peer reviewer's comment: Finally, there will be a few grammatical errors that should be checked.
Authors' response: Thanks. We have re-checked the manuscript for grammatical errors.

Peer reviewer's comment: I am grateful for the opportunity to read this manuscript and share my observations which I hope will help guide the authors in determining merit worthiness for indexing as well as contribute to continued discussions.
Authors' response: Thank you for your helpful feedback which we believe has helped to improve the quality of the manuscript.

Competing Interests: None

General comments
We commend the authors for attempting to conduct a systematic review on one of the most controversial topics related to the COVID-19 pandemic: SARS-CoV-2 transmission. This is an important effort that required much dedication and careful analysis. Unfortunately, we think this manuscript falls short of scientific quality and utility due to major methodologic and conceptual flaws.

First, this systematic review in its current version fails to provide an accurate and updated picture of the existing evidence. We reviewed this manuscript in February 2022, two years into the pandemic, and while SARS-CoV-2 transmission remains a topic of great relevance, the picture regarding the modes of transmission is much clearer now than one year ago due to numerous epidemiologic and lab-based studies. Given this evidence, the WHO and the general scientific community agree that SARS-CoV-2 can be transmitted via droplet, short-range aerosol, long-range aerosol, and less frequently via fomites. This systematic review should be updated to reflect the most recent evidence.

Second, and most importantly, there are methodological flaws, conceptual concerns, and unsupported conclusions, as detailed below. Systematic reviews are designed to summarize evidence on specific questions or focused problems with pre-defined criteria to bring understanding and clarity through insightful analyses (even if no meta-analyses are conducted) of existing evidence. Close contact is not only poorly defined in most articles, but is actually addressed in less than a half of the articles included. Importantly, close contact is not a transmission mechanism itself, rather a feature of transmission mechanism(s). The authors erroneously conclude that studies that identified identical strains in close contacts using genome sequencing and phylogenetic analysis support transmission via respiratory droplets. The authors do not acknowledge that short-range aerosol transmission is also a possible (and a likely one) explanation.

Note that given the absence of line numbers, we are not providing numbered comments.

Introduction

- The introduction should be updated as statistics are over one year old (March 2021).

- The authors mention that the “spread of the virus appears to be slowing”. This statement is not necessarily true considering the recent, recurring, and constantly evolving waves of infection attributed to increasingly transmissible variants of SARS-CoV-2. Furthermore, no citation is provided for this statement.

- "Current evidence from epidemiologic and virologic studies suggest SARS-CoV-2 is primarily transmitted via respiratory droplets and direct and indirect contact". This sentence is not properly supported by current data; the authors rather cited two WHO 2021 resources. The authors must acknowledge airborne transmission – a route of transmission accepted by both WHO and CDC. Note that respiratory transmission of inhalable particles is the dominant mode of transmission, especially short-range. Indirect droplet / contact / fomite transmission is estimated to be minor.
    - Recommended references: Zhang & Duchaine 2020[1] and Leung 2021[2].
- The aim of this study is to assess the evidence from primary studies and existing systematic reviews investigating the role of close contact on SARS-CoV-2 transmission. This is aligned with the manuscript title ("SARS-CoV-2 and the role of close contact in transmission..."), the introduction, the methods, and figure and table titles. However, one major challenge is that the "close contact" framework is neither clearly defined in the literature nor is it often standardized in methods of primary studies. Authors address several aspects of transmission, from settings to distance, populations, testing/lab methods (PCR, serology, viral culture, GS and phylogenetic analysis), attack rates, risk of infection, etc. We agree that

all of these are variables that influence or describe transmission. But close contact is only defined in 46.8% of included studies which causes concern over the use of consistently applied inclusion criteria. This systematic review seems to evaluate different aims and ends providing general descriptions of different subtopics related to transmission, not only to close contact. It is not appropriate for this study on the role of close contact to make such inference on the interaction between an infector and an infectee if not explicitly stated in the primary study.

Terminology

- The authors seem to be using the CDC criteria but this is not clarified in the box definition and the citation link seems to be inadequate.

- It should be "2 days prior to positive test" instead of "2 days prior to test specimen collection".

- Some of the references are textbooks or web resources not easy to navigate or links are not active. Authors are encouraged to use the most relevant scientific articles on COVID-19 wherever possible.

- Synonyms often used to close contact are close/short range and close proximity. The latter could be more beneficial since the word “contact” is often understood as physical and conspicuous encounters.

- While it's understandable that definitions are needed to assess evidence, it is equally important to mention their limitations from the outset. For example, close contact is arbitrary for purposes of contact tracing—we know that the definition results in missing cases of exposure and infection at longer ranges.

Methods

- The inclusion of articles identified via preprint servers is justifiable if the search criteria include very recent dates in an attempt to capture the most recent research. However, this systematic review only includes articles up to December 20th 2020 – if the authors choose to use this date or a recent one, articles on preprint servers should not be included.

- The search strategy is not reproducible and more detail is required. For example, a detailed search strategy for the WHO COVID-19 database, LitCovid, medRxiv, and Google Scholar are not included in the Appendix 2. Nor is it clear exactly which keywords were used in the PubMed search, for example, were other terms used to capture the concept of duration and proximity of exposure?

- It is not clear if authors defined “close contact” for inclusion in their systematic review.
- Additional detail is required to explain how the QUADAS-2 tool was adapted for this study and if or how it was validated for this purpose.
https://figshare.com/articles/figure/Extended_data_SARS-CoV-2_and_the_Role_of_Close_Contact_in_Transmission_A_Systematic_Review/14312630/1?file=27243050

- The QUADAS-2 tool was designed for studies primarily designed as diagnostic accuracy studies and its use is likely to fall short to assess the quality of studies for this systematic review.

Analyses of primary studies

- Although authors have included extended data containing the protocol and references to included and excluded studies, this remains outdated (March 2021). Several features are discussed and while some of them could suggest close contact transmission, there is quite a bit of heterogeneity in how these studies of transmission inform the role of close contact.

- While we agree that close-contact transmission is a dominant feature of SARS-CoV-2 transmission through the inhalation of respiratory particles, this systematic review does not help advance the aim mentioned - understanding the role of close contact. The authors could revise this work so it separately addresses features of transmission using standardized or limited definitions for each one. Attribution of such analyses to close contact (i.e., its potential role) should result from the interpretation of such findings altogether rather than from "direct assessment of the impact of close contact in transmission" since most studies do not define or measure close contact systematically.

Analyses of reviews

- The authors included 10 systematic reviews allegedly investigating close-contact SARS-CoV-2 transmission. Some concerns make questionable the inclusion of such heterogeneous publications for an analysis that at best describes these almost individually without advancing the understanding of the role of close contact in SARS-CoV-2 transmission, which is the ultimate purpose of the authors' systematic review. It is expected that studies included in such publications are primarily observational, since randomized designs are complex and it remains unclear how research should ideally address gaps in our understanding of transmission. Findings of some of the included reviews (Li, Ludvigsson, Zhu) are not described with regard to close contact, but only to population groups; others are only mentioned with regard to asymptomatic infection or attack rates. We find this analysis in general unhelpful.

- The authors analyze features different from close contact in the sections following "Primary studies". All these analyses are related to primary studies, so this should be reorganized for clarity. Again, there is a detailed description of studies that do not address close contact, e.g., "The result of one study (Rosenberg 2020) showed that the incidence of infection significantly increased with age ($p<0.0001$), while those from another study (Poletti 2020) showed that being 70 years or older was associated with a significantly increased risk of SARS-CoV-2-related death ($p<0.001$),"

Discussion

- Authors should be careful in interpreting what their systematic review found, for instance that many studies report household transmission suggests that transmission occurs in indoor environments with higher exposure. Exposure results from concentration and time of contact with infectious respiratory particles. It, therefore, depends on a mix of frequency of contacts, range of contact, and infectiousness of index cases. But household transmission may perfectly encompass risk of infection beyond 3 m, 6 m, or any other definition of close contact. We do expect that the risk of infection is greatest with the longest contact, though, but the definition of a close contact remains nebulous and the associated risk could vary depending on the environmental conditions that favor transmission. Because the purpose of this systematic review is to address transmission, the authors must discuss at least generally the interplay of these factors. SARS-CoV-2 transmission is a complex phenomenon that depends on the interaction between viral properties (infectious dose and infectivity correlates), the host and their features (breathing rate, respiratory tract morphology, target tissues, receptor distribution, host barriers, immune responses), and the environment

(temperature, humidity, salinity, pH, the medium or materials of the contaminated objects or surfaces, ventilation/airflow, ultraviolet radiation). Authors also should acknowledge that existing evidence suggests that transmission in close-contact settings is likely to be dominated by short-range respiratory inhalation of infectious virions.

- The authors superficially mention the role of face masks in decreasing the risk of transmission from the pediatric population. This is a dangerous misinterpretation of evidence of two things that should be analyzed separately, i.e., 1) the efficacy of respiratory protection and 2) the risk of transmissibility from different populations. Certainly, this review was not designed to assess either of these aspects as a research question. As for respiratory protection, not all masks (or respirators) are expected to provide the same degree of protection. And if not correctly/consistently worn, they may not reduce risk. As for the usually overclaimed risk of children to transmit SARS-CoV-2, many potential confounders easily make this group appear highly contagious but it is unlikely this is due to intrinsic features of that population. Therefore, claims about it should be carefully framed to avoid stigmatization or unfair focalization and perceived efficacy of preventive strategies.

- Discussion unrelated to close contact is seen, e.g., "being elderly is also associated with increased risks of transmission and mortality".

- "The positive results of viral cultures observed in two studies support the results of PCR and serologic tests showing that close contact setting was associated with transmission of SARS-CoV-2".
    - We are unsure how this manuscript supports this conclusion. Similarly, this conclusion is not supported by the data "The positive findings from all 10 studies that performed GS and phylogenetic analysis with identical strains supports the hypothesis that close contact setting is associated with SARS-CoV-2 transmission through respiratory droplets or direct contact."
- We agree with the authors on the high heterogeneity of existing studies and that "The variations observed in the definitions of close contacts also cast further doubts on the validity of overall results."

- "The results of our review are consistent with several guidelines suggesting that close contact with index cases can result in transmission of SARS-CoV-2"
    - The authors acknowledge that the evidence for close contact transmission is only low-to-moderate quality, thus, it is a stretch to say that close contact is consistently demonstrated as a risk factor. Guidelines have been evolving throughout the pandemic and while close contact may be associated with increased risk of transmission, this study could provide much stronger evidence if transmission properties were assessed in a clearly defined, systematic, and reproducible way.
- "Our findings are also consistent with those of a systematic review which concluded that face masks are effective for preventing transmission of respiratory viruses."
    - It is unclear how this systematic review regarding the role of close contract on transmission events contributes to the discussion regarding the role of face masks – more description is needed to make this link explicit. Furthermore, the efficacy of face masks is a complex topic and confounded by a number of factors.

Necessary updates

- Several of the preprints included in the systematic review and/or cited in the manuscript

have been published; given that this manuscript is outdated and an update is needed, authors should take that opportunity to update preprints that have been published and make sure their findings remain unchanged and adjust accordingly. Some of the preprints now published are:

Author Response 29 Jun 2022

IGHO ONAKPOYA, University of Oxford, Oxford, UK

Peer reviewers, comment: We commend the authors for attempting to conduct a systematic review on one of the most controversial topics related to the COVID-19 pandemic: SARS-CoV-2 transmission. This is an important effort that required much dedication and careful analysis. Unfortunately, we think this manuscript falls short of scientific quality and utility due to major methodologic and conceptual flaws.
Authors' response: We thank the reviewers for their positive comments and constructive criticisms. We have extensively revised the manuscript to address their concerns.

Peer reviewers' comment: First, this systematic review in its current version fails to provide an accurate and updated picture of the existing evidence. We reviewed this manuscript in February 2022, two years into the pandemic, and while SARS-CoV-2 transmission remains a topic of great relevance, the picture regarding the modes of transmission is much clearer now than one year ago due to numerous epidemiologic and lab-based studies. Given this evidence, the WHO and the general scientific community agree that SARS-CoV-2 can be transmitted via droplet, short-range aerosol, long-range aerosol, and less frequently via fomites. This systematic review should be updated to reflect the most recent evidence.
Authors' response: The review was submitted in March last year at the start of the pandemic; however, it took a long time before undergoing peer review. We have now updated the review to reflect the most recent evidence focused on the transmission

associated with close contact. We updated our searches up till 30/04/2022.

Peer reviewers' comment: Second, and most importantly, there are methodological flaws, conceptual concerns, and unsupported conclusions, as detailed below. Systematic reviews are designed to summarize evidence on specific questions or focused problems with pre-defined criteria to bring understanding and clarity through insightful analyses (even if no meta-analyses are conducted) of existing evidence. Close contact is not only poorly defined in most articles, but is actually addressed in less than a half of the articles included. Importantly, close contact is not a transmission mechanism itself, rather a feature of transmission mechanism(s). The authors erroneously conclude that studies that identified identical strains in close contacts using genome sequencing and phylogenetic analysis support transmission via respiratory droplets. The authors do not acknowledge that short-range aerosol transmission is also a possible (and a likely one) explanation.
Authors' response: We used the term “close contact settings” for our review, and we acknowledge variations in the definitions of close contact across the studies included in our review (see Table 3). We do not make any claims that close contact is a transmission mechanism but is associated with transmission from any of a number of mechanisms. We have added (with reference) that short-range aerosol transmission is a possible explanation for the identified identical strains in close contacts.

Peer reviewers' comment: Note that given the absence of line numbers, we are not providing numbered comments.
Authors' response: OK

Introduction
Peer reviewers' comment:

- The introduction should be updated as statistics are over one year old (March 2021).

The authors mention that the “spread of the virus appears to be slowing”. This statement is not necessarily true considering the recent, recurring, and constantly evolving waves of infection attributed to increasingly transmissible variants of SARS-CoV-2. Furthermore, no citation is provided for this statement.
Authors' response: We have updated the searches to April 2022.
We have provided a citation to show that the infection rate is decreasing (https://www.ons.gov.uk/peoplepopulationandcommunity/healthandsocialcare/conditionsanddiseases/articl), and have also noted that the virus continues to evolve.

Peer reviewers' comment:

- "Current evidence from epidemiologic and virologic studies suggest SARS-CoV-2 is primarily transmitted via respiratory droplets and direct and indirect contact". This sentence is not properly supported by current data; the authors rather cited two WHO 2021 resources. The authors must acknowledge airborne transmission – a route of transmission accepted by both WHO and CDC. Note that respiratory transmission of inhalable particles is the dominant mode of transmission, especially short-range. Indirect droplet / contact / fomite transmission is estimated to be minor.
    - Recommended references: Zhang & Duchaine 20201 and Leung 20212.

Authors' response: We wish to thank the reviewer for this comment. We have updated the

information and referenced the CDC and the WHO. The CDC statement suggests that exposure with infection occurs in 3 principal ways including inhalation of fine respiratory droplets, deposition of respiratory droplets and particles on exposed mucous membranes, splashes and sprays 'and touching mucous membranes with hands soiled by virus contained in respiratory fluids" (Scientific Brief: SARS-CoV-2 Transmission | CDC). They openly acknowledge the relative contributions of the modes of transmission outlined are unquantified and difficult to establish. We have revised the statement to state that the virus is primarily transmitted through exposure to infectious respiratory fluids such as fine aerosols, respiratory droplets, and added a further reference (https://www.cdc.gov/coronavirus/2019-ncov/science/science-briefs/sars-cov-2-transmission.html). The WHO states "available evidence continues to suggest that SARS-CoV-2 can spread from an infected person's mouth or nose in small liquid particles when the person coughs, sneezes, sings, breathes or talks, by inhalation or inoculation through the mouth, nose or eyes. These liquid particles are different sizes, ranging from larger 'respiratory droplets' to smaller 'aerosols." Current evidence suggests that the virus spreads mainly between people who are in close contact with each other, typically within 1 metre, They also indicate that "the virus can also spread to others through aerosols at longer (beyond the typical 1 metre distance) distances. The risk of long-distance aerosol transmission is higher in poorly ventilated and/or crowded indoor settings" and further discuss transmission through fomites but acknowledge data is limited. Similar to the CDC they indicate the many challenges in working out the presence and transmission of infectious viruses. Rather than state the respiratory transmission of inhalable particles is the dominant mode of transmission we would prefer a more cautious scientifically based response and acknowledge the gap in knowledge in this area. Infection prevention and control during health care when coronavirus disease (COVID-19) is suspected or confirmed (who.int)

Peer reviewers' comment:

- The aim of this study is to assess the evidence from primary studies and existing systematic reviews investigating the role of close contact on SARS-CoV-2 transmission. This is aligned with the manuscript title ("SARS-CoV-2 and the role of close contact in transmission..."), the introduction, the methods, and figure and table titles. However, one major challenge is that the "close contact" framework is neither clearly defined in the literature nor is it often standardized in methods of primary studies. Authors address several aspects of transmission, from settings to distance, populations, testing/lab methods (PCR, serology, viral culture, GS and phylogenetic analysis), attack rates, risk of infection, etc. We agree that all of these are variables that influence or describe transmission. But close contact is only defined in 46.8% of included studies which causes concern over the use of consistently applied inclusion criteria. This systematic review seems to evaluate different aims and ends providing general descriptions of different subtopics related to transmission, not only to close contact. It is not appropriate for this study on the role of close contact to make such inference on the interaction between an infector and an infectee if not explicitly stated in the primary study.

Authors' response: We thank the reviewer for this comment to which we have thought a great deal. We can respond by stating that although only 46.8% (now 39.1%) defined close contact, the authors in the other included studies reported within their studies that they

were investigating close contact. We acknowledge that not all studies provided precise definitions and that is a limitation. We set out to summarize the evidence from published studies that assess the association with close contact transmission in COVID-19.

As stated earlier, we have used the term “close contact settings” for our review.

Terminology
Peer reviewers' comment:
- The authors seem to be using the CDC criteria but this is not clarified in the box definition and the citation link seems to be inadequate.

Authors' response: Thanks. We have revised the definition.

Peer reviewers' comment: It should be "2 days prior to positive test" instead of "2 days prior to test specimen collection"
Authors' response: Thanks. We have revised the text accordingly.

Peer reviewers' comment: Some of the references are textbooks or web resources not easy to navigate or links are not active. Authors are encouraged to use the most relevant scientific articles on COVID-19 wherever possible
Authors' response: We have used the updated citations for the relevant articles.

Peer reviewers' comment: Synonyms often used to close contact are close/short range and close proximity. The latter could be more beneficial since the word “contact” is often understood as physical and conspicuous encounters.
Authors' response: We have broadly used “close contact setting” to allow us to capture the range of studies assessing transmission characteristics of SARS-CoV-2. We appreciate the reviewers’ suggestions of close proximity/range. However, these may be more useful for more focused review questions as they also have their limitations, e.g., direct contact would not be covered by these; however, direct contact has been described as a subset of close contact in some studies.

Peer reviewers' comment:
- While it's understandable that definitions are needed to assess evidence, it is equally important to mention their limitations from the outset. For example, close contact is arbitrary for purposes of contact tracing—we know that the definition results in missing cases of exposure and infection at longer ranges.

Authors' response: Thank you for this suggestion. We have noted this in the limitations section.

Peer reviewers' comment:
- The inclusion of articles identified via preprint servers is justifiable if the search criteria include very recent dates in an attempt to capture the most recent research. However, this systematic review only includes articles up to December 20th 2020 – if the authors choose to use this date or a recent one, articles on preprint servers should not be included.

Authors' response: We have updated the searches and used the most up-to-date citations for the included studies.

Peer reviewers' comment: The search strategy is not reproducible and more detail is required. For example, a detailed search strategy for the WHO COVID-19 database, LitCovid, medRxiv, and Google Scholar are not included in the Appendix 2. Nor is it clear exactly which keywords were used in the PubMed search, for example, were other terms used to capture the concept of duration and proximity of exposure?
Authors' response: Thank you. We have included the full search strategy.

Peer reviewers' comment:
- It is not clear if authors defined “close contact” for inclusion in their systematic review.

Authors' response: We used the CDC and WHO definitions (see Box 1).

Peer reviewers' comment: Additional detail is required to explain how the QUADAS-2 tool was adapted for this study and if or how it was validated for this purpose.
https://figshare.com/articles/figure/Extended_data_SARS-CoV-2_and_the_Role_of_Close_Contact_in_Transmission_A_Systematic_Review/14312630/1?file=27243050
Authors' response: We did not use all the domains in QUADAS-2 and have clarified this in the manuscript methods section. We did not validate the checklist, and have noted this in our limitations.

Peer reviewers' comment:
- The QUADAS-2 tool was designed for studies primarily designed as diagnostic accuracy studies and its use is likely to fall short to assess the quality of studies for this systematic review.

Authors' response: QUADAS-2 is used to assess reporting quality in diagnostic reviews. See https://www.bristol.ac.uk/media-library/sites/quadas/migrated/documents/quadas2reportv4.pdf. As noted in our methods, we adapted the checklist for the review.

Analyses of primary studies
Peer reviewers' comment:
- Although authors have included extended data containing the protocol and references to included and excluded studies, this remains outdated (March 2021). Several features are discussed and while some of them could suggest close contact transmission, there is quite a bit of heterogeneity in how these studies of transmission inform the role of close contact.

Authors' response: We have updated the searches and included the most up-to-date citations.

Peer reviewers' comment:
- While we agree that close-contact transmission is a dominant feature of SARS-CoV-2 transmission through the inhalation of respiratory particles, this systematic review does not help advance the aim mentioned - understanding the role of close contact. The authors could revise this work so it separately addresses features of transmission using standardized or limited definitions for each one. Attribution of such analyses to close contact (i.e., its potential role) should result from the interpretation of such

findings altogether rather than from "direct assessment of the impact of close contact in transmission" since most studies do not define or measure close contact systematically.

Authors' response: We included a table showing how the included studies defined close contact. Our objective was to identify, appraise and summarise the evidence from studies investigating transmission in close contact settings. It is equally possible that with close contact there may be transmission via large respiratory droplets and direct physical contact as well as the possibility of short-range fine aerosol and in all fairness, it should be stated as such and not that inhalation is the dominant route as this reviewer contends. It is best to be consistent with all possibilities as suggested by the CDC and WHO and many other publications.

Analyses of reviews

Peer reviewers' comment:

- The authors included 10 systematic reviews allegedly investigating close-contact SARS-CoV-2 transmission. Some concerns make questionable the inclusion of such heterogeneous publications for an analysis that at best describes these almost individually without advancing the understanding of the role of close contact in SARS-CoV-2 transmission, which is the ultimate purpose of the authors' systematic review. It is expected that studies included in such publications are primarily observational, since randomized designs are complex and it remains unclear how research should ideally address gaps in our understanding of transmission. Findings of some of the included reviews (Li, Ludvigsson, Zhu) are not described with regard to close contact, but only to population groups; others are only mentioned with regard to asymptomatic infection or attack rates. We find this analysis in general unhelpful.

Authors' response: Thanks for this comment. The included systematic reviews are considered appropriate since they do fit the definition of close contact based on our original protocol - this relates to structural and population settings. We can discuss the limitations of these reviews and the included studies. Li, Ludvigsson and Zhu fit the definitions. See https://www.ecdc.europa.eu/en/covid-19/surveillance/surveillance-definitions. Some of the findings from the reviews are helpful. Indeed at least 2 reviews included only studies with high reporting quality.

Peer reviewers' comment:

- The authors analyze features different from close contact in the sections following "Primary studies". All these analyses are related to primary studies, so this should be reorganized for clarity. Again, there is a detailed description of studies that do not address close contact, e.g., "The result of one study (Rosenberg 2020) showed that the incidence of infection significantly increased with age ($p<0.0001$), while those from another study (Poletti 2020) showed that being 70 years or older was associated with a significantly increased risk of SARS-CoV-2-related death ($p<0.001$),"

Authors' response: Thank you for pointing this out and we have revised the section on primary studies. We have enumerated the definitions of close contacts in the included studies in Table 3 and reported that several studies did not report a definition). Several studies showed that being elderly was significantly associated with increased risk of infection. Rosenberg 2020 included household contacts. We have revised the statement.

Discussion

Peer reviewers' comment:

- Authors should be careful in interpreting what their systematic review found, for instance that many studies report household transmission suggests that transmission occurs in indoor environments with higher exposure. Exposure results from concentration and time of contact with infectious respiratory particles. It, therefore, depends on a mix of frequency of contacts, range of contact, and infectiousness of index cases. But household transmission may perfectly encompass risk of infection beyond 3 m, 6 m, or any other definition of close contact. We do expect that the risk of infection is greatest with the longest contact, though, but the definition of a close contact remains nebulous and the associated risk could vary depending on the environmental conditions that favor transmission. Because the purpose of this systematic review is to address transmission, the authors must discuss at least generally the interplay of these factors. SARS-CoV-2 transmission is a complex phenomenon that depends on the interaction between viral properties (infectious dose and infectivity correlates), the host and their features (breathing rate, respiratory tract morphology, target tissues, receptor distribution, host barriers, immune responses), and the environment (temperature, humidity, salinity, pH, the medium or materials of the contaminated objects or surfaces, ventilation/airflow, ultraviolet radiation). Authors also should acknowledge that existing evidence suggests that transmission in close-contact settings is likely to be dominated by short-range respiratory inhalation of infectious virions.

Authors' response: Thank you. We have enumerated the complex range of factors at play and the epidemiologic associations in relation to close contact transmission (with references) and have acknowledged the various potential modes of transmission. We agree that transmission is a complex phenomenon and indeed is poorly understood. Musing about issues surrounding the biology of virus particles is beyond the scope of our review which focuses on epidemiologic associations.

Peer reviewers' comment: The authors superficially mention the role of face masks in decreasing the risk of transmission from the pediatric population. This is a dangerous misinterpretation of evidence of two things that should be analyzed separately, i.e., 1) the efficacy of respiratory protection and 2) the risk of transmissibility from different populations. Certainly, this review was not designed to assess either of these aspects as a research question. As for respiratory protection, not all masks (or respirators) are expected to provide the same degree of protection. And if not correctly/consistently worn, they may not reduce risk. As for the usually overclaimed risk of children to transmit SARS-CoV-2, many potential confounders easily make this group appear highly contagious but it is unlikely this is due to intrinsic features of that population. Therefore, claims about it should be carefully framed to avoid stigmatization or unfair focalization and perceived efficacy of preventive strategies.

Authors' response: We do not believe we are being superficial but rather trying to stay true to the findings. Our statements regarding the effectiveness of face masks are based on the findings from the included studies and we need to stay focused on the findings and avoid making speculative statements. We have added a caveat that there is uncertainty about the extent to which the different types of masks influence the risk of transmission.

Peer reviewers' comment: Discussion unrelated to close contact is seen, e.g., "being elderly is also associated with increased risks of transmission and mortality".
Authors' response: Thank you for pointing this out. We have removed the statement.

Peer reviewers' comment:
- The positive results of viral cultures observed in two studies support the results of PCR and serologic tests showing that close contact setting was associated with transmission of SARS-CoV-2".
    - We are unsure how this manuscript supports this conclusion. Similarly, this conclusion is not supported by the data "The positive findings from all 10 studies that performed GS and phylogenetic analysis with identical strains supports the hypothesis that close contact setting is associated with SARS-CoV-2 transmission through respiratory droplets or direct contact."

Authors' response: We have revised the statement to indicate that transmission can occur in close contact settings.

Peer reviewers' comment: We agree with the authors on the high heterogeneity of existing studies and that "The variations observed in the definitions of close contacts also cast further doubts on the validity of overall results."
Authors' response: Thank you.

Peer reviewers' comment:
- "The results of our review are consistent with several guidelines suggesting that close contact with index cases can result in transmission of SARS-CoV-2"
    - The authors acknowledge that the evidence for close contact transmission is only low-to-moderate quality, thus, it is a stretch to say that close contact is consistently demonstrated as a risk factor. Guidelines have been evolving throughout the pandemic and while close contact may be associated with increased risk of transmission, this study could provide much stronger evidence if transmission properties were assessed in a clearly defined, systematic, and reproducible way.

Authors' response: Thank you for this comment. We have revised the sentence to discuss the “association” with transmission as opposed to "can result in transmission”. We have added a caveat to note that guidelines keep evolving based on emerging evidence.

Peer reviewers' comment:
- "Our findings are also consistent with those of a systematic review which concluded that face masks are effective for preventing transmission of respiratory viruses."

It is unclear how this systematic review regarding the role of close contract on transmission events contributes to the discussion regarding the role of face masks – more description is needed to make this link explicit. Furthermore, the efficacy of face masks is a complex topic and confounded by a number of factors.
Authors' response: We have revised the statements. We have deleted the texts relating to mortality in the elderly.

Peer reviewers' comment: Necessary updates
- Several of the preprints included in the systematic review and/or cited in the

manuscript have been published; given that this manuscript is outdated and an update is needed, authors should take that opportunity to update preprints that have been published and make sure their findings remain unchanged and adjust accordingly. Some of the preprints now published are:

Helsingen 2020[3]
Paireau 2020[4]
Kuwelker 2020[5]
Lyngse 2020[6]
Jones 2020[7]
Chen 2020[8]
Fontanet 2020[9]
Armann 2020[10]
Charlotte 2020[11]
Angulo-Bazan 2020[12]

Authors' response: Thank you. We have now updated the citations for the references.

Competing Interests: None

Version 1

Reader Comment 23 Jun 2021

Trish Greenhalgh, University of Oxford, Oxford, UK

RESPONSE TO DR ONAKPOYA *ET AL.* TO THEIR RESPONSE (DATED 14TH JUNE 2021) TO OUR ORIGINAL COMMENT ON THEIR PAPER

We thank Dr. Onakpoya *et al.* for the response to our comment. However, most of the points in our comment have not been addressed at all. They provided a longer response only to the virology comment, but all our other comments are just as important. Here we provide brief responses to each of the points in the response from Onakpoya *et al*., and call attention to the questions that are still missing a response.

Authors' response to our comment #1.
The authors said: *"Thank you. We have found conflicting definitions of particle size and the issue of short vs long range transmission is complex and requires a common set of agreed upon definitions and more study."*

This response did not address the concern we raised in our original Comment 1, which pointed out that the possibility of short-range aerosol transmission being a major (and potentially dominant) contributor to “close contact” transmission was never mentioned in their review. We consider this a

serious omission for the reasons set out in our original comment.

Regarding particle size: It is clear to aerosol scientists that the 5 micron separation between droplets and aerosols discussed in WHO's latest scientific brief (World Health Organization 2020) is very erroneous. The correct separation is approximately 100 microns, as originally reported by Wells (Wells 1934), confirmed by others (Xie *et al*. 2007) and recently reaffirmed by the US National Academies of Science, Engineering, and Medicine (Samet *et al*. 2021; Prather *et al.* 2020). The 5 micron error appears to have arisen at the CDC in the 1960s, by confusing the particle size that reaches the deep lung to infect in pulmonary tuberculosis with the particle size that falls to the ground in 1-2 meters from the infected person (Randall *et al*. 2021).

Authors' response to our comment #2.
The authors said: *"As we make clear in the text, we draw no definitive conclusions on this issue. We do not "believe" anything without solid evidence."*

This response did not address the concern in our Comment 2, which was that equating ease of infection in close proximity with droplet transmission, as the authors appear to do in their paper, is a major conceptual error. For example, the following text appears in the paper:

"Current evidence from epidemiologic and virologic studies suggest SARS-CoV-2 is primarily transmitted via respiratory droplets and direct and indirect contact."

How was that conclusion reached? Two WHO documents are cited, where the main justification for large droplet transmission is that transmission under close proximity is important. If the authors agree that no conclusion about the importance of droplet transmission can be reached from studies of transmission in close proximity, this should be clearly stated in the revised version.

In addition, the authors did not reply about whether a separate review on large droplet transmission is forthcoming. This is a topic of the utmost importance, since WHO maintains that large droplets are the main mode of SARS-CoV-2 transmission. It is very unclear what evidence supports that determination.

Authors' response to our comment #4.
The authors said: *"Once an agreed upon set of revised definitions is achieved, we and others would use them in any reviews of the evidence."*

We respectfully suggest that the problem here is not one of agreed-upon definitions but of mechanisms of transmission. We question the authors' stance that the way viral transmission is conceptualised must remain flawed until everyone agrees on a definition of what counts as close contact.

Authors' response to our comment #5.
The authors said: *"We do not conflate the two [close contact transmission and large droplet transmission], hence the need for separate reviews."*

This response appears conceptually flawed. If close contact transmission includes droplet, aerosol

(short-range airborne), as well as indirect contact (fomite) transmission, surely the scope of these reviews overlaps?

We suggest adopting the clearer definition of mechanisms as surface touch, large droplet spray / deposition, and aerosol inhalation suggested by Y. Li (2021) and adopted by the US Centers for Disease Control and Prevention (CDC 2021).

Authors' response to our comment #6.
The authors said: *"The WHO guidance has not changed."*

This response overlooks the fact that we did not say that WHO guidance had changed. We said that the WHO had stated that airborne transmission can occur. To verify our original claim, on 30 April 2021, the WHO updated its 'Covid-19 – how is it transmitted?' page (World Health Organization 2021) with the following statement:

"Current evidence suggests that the virus spreads mainly between people who are in close contact with each other, typically within 1 metre (short-range). A person can be infected when aerosols or droplets containing the virus are inhaled or come directly into contact with the eyes, nose, or mouth. The virus can also spread in poorly ventilated and/or crowded indoor settings, where people tend to spend longer periods of time. This is because aerosols remain suspended in the air or travel farther than 1 metre (long-range)." (our emphasis).

The authors' response does not address our main point here, which was that the authors' statement. *"Current evidence from epidemiologic and virologic studies suggest SARS-CoV-2 is primarily transmitted via respiratory droplets and direct and indirect contact"*, is now outdated, outmoded and frankly, dangerous. In our original comment, we set out several peer-reviewed papers (which are already highly-cited) summarising the evidence base on airborne transmission. We ask, again, that the authors engage with them.

The authors declare "no conflicts of interest". Yet one of the authors, Professor Conly, is the chair of the WHO group that produces the guidelines that have not changed. We question the mechanisms of scientific governance within the WHO which allow the chair of a guideline committee whose views are out of step with mainstream scientific opinion to a) co-author a review "commissioned and paid for by the WHO" which informs the decision-making of that committee, b) present that review as dispassionate by not declaring his WHO position, and c) ignore the WHO's own published advice on mode of transmission.

Authors' response to our comment #7.
The authors said: *"In our reviews we present and synthesize the original authors' findings and have not ruled out any form of airborne transmission."*

We respectfully suggest that "not ruling out" airborne transmission while failing to engage with a strong, consistent and growing evidence base (such as the major indoor / outdoor difference in transmission) that supports a major role for this mode of transmission is both scientifically and ethically inadequate at a time when the world urgently needs policies that accurately reflect the mechanism of transmission of this deadly virus.

Authors' response to our comment #8.
The authors said: *"We are working on a method for identifying high quality evidence of transmission causality and testing it by applying it to our future reviews. (See: https://www.preprints.org/manuscript/202104.0633/v1)."*

Once again our original comment has not been addressed, namely the fact that positive viral culture from clinical specimens was automatically associated with close contact transmission, but not considered for airborne transmission.

For a team that wants to identify high-quality evidence, it would appear that sufficient strength in all the major disciplines involved would be a must. For a disease that a major part of the scientific community thinks is dominantly airborne, it would appear critical to include as part of your team experts on aerosols and airborne transmission. We remain surprised and shocked that the review team includes nobody with expertise in airborne transmission of disease, and we question the WHO's decision to award a contract to a team which lacked this crucial expertise.

Authors' response to our comment #9.
The authors said: *"We are happy to expand on the methods used to rate the reporting quality of the included studies."*

We respectfully suggest that an adequate response to our comment would include such an expansion.

Authors' response to our comment #10.
The authors made a number of points here.

Firstly, the authors said: *"PCR serves as a trivially simple and fast tool for detecting pathogens, but any virologist would tell you that the link between a nucleic acid signal and an infectious unit are complex and difficult to establish. There's lots of nucleic acid, some small fraction is packaged, and some yet smaller fraction of packaged viruses is infectious. Some aerosol publications assume that 1 nucleic acid signal = 1 infectious particle. This is wrong, in fact for SARS-CoV-2 the ratio is more typically >100,000 if one carefully calibrates the Ct values with internal standards."*

In response, and drawing on our collective expertise in virology, we respectfully point out that:

- PCR amplifies viral RNA, each cycle doubling the target RNA (think of rice grains on a chess board), so that after 30 and 40 cycles (2 to the 30th and 40th power), the number of copies of the target RNA is ~1 billion and ~1 trillion copies. So the ratio should be 1 viable virus to many, many RNA copies. Not the other way around.

- We have not seen any serious, widely accepted claim for 1 viable virus to 1 PCR amplified RNA copy before, for any virus. To give one example, using digital PCR in a study coauthored by one of us in relation to influenza vaccine virus (Kalliomäki *et al*, page 60), we found that 1 FFU was equal to about 94 RNA copies.

Secondly, the authors said the following: *"The authors state that culturing viruses can be tricky. SARS-*

CoV-2 forms large distinctive plaques on a variety a cell lines, as long as they express the ACE2 receptor. Many different cell types have been tested, including cells designed to enhance the growth (e.g. TMPRSS2), all yield decent titers in the 10^6 to 10^ PFU/mL range. Similar titers are retrieved from the most infectious of patient specimens. Yes one needs BSL3 containment, but nowadays if one is looking for infectious SARS-CoV-2, there are no reasons not to grow it."

In response, and drawing on our relevant interdisciplinary expertise, we respectfully point out that this comment needs to be contextualised in that air-sampling substantially disrupts and inactivates lipid-enveloped viruses. We know there is a massive loss of viable virus with such viruses in air samples - as we showed here in our earlier paper on influenza (Brown *et al.* 2015). That study also showed that RNA copies amplified by PCR also vastly exceed the viable virus count - supporting the earlier point made above. But this also means that absence of detected viable virus does not mean that aerosol transmission cannot happen, and the degree to which RNA detection alone can indicate this potential will depend on the context and the availability of other related epidemiological data for that event.

In summary: in aerosol samples, the amount of virions in samples is expected to be low and this will translate into difficulties in culturing viruses, since isolation in cell culture is inherently less sensitive than molecular detection. This is compounded by the fact, well known to virologists, that **aerosol collection techniques damage virions and diminish infectivity**, so recovery of **any** infectious SARS-CoV-2 in culture would be highly significant (and this has been done by some groups already) and also almost certainly an underestimate. Low concentration of airborne pathogens is to be expected in aerosol transmission, for example in their studies demonstrating TB transmission from tuberculosis wards Riley *et al.* (Sultan *et al.* 1960, Riley *et al.* 1962) found a concentration of about 1 bacillus per 10 000 cubic feet. Aerosol transmission can nonetheless occur because of the very large volume of air inhaled by humans.

In addition, the authors said: *"The interesting thing is that when one calculates the titer of virus in culture (TCID50) and measure the minimal infectious dose (MID) in the highly susceptible hamster model, the numbers are surprisingly congruent. The conclusion is that one plaque-forming unit in culture is one hamster infectious unit as well. If there's something wrong with using cell cultures to detect virus and measure titer, one would have to posit that the same exact problem characterizes the hamster model."*

In response, we suggest that the authors appear to be missing the point. We are talking about whether or not the isolation of live virus from air samples is a reliable indicator of the aerosol spread of the virus between people - and the degree to which RNA detection can indicate this. We are saying that the lack of such viable virus detection in air-sampling studies does not exclude this possible route of transmission because:

- The air-sampling may be occurring too distant from the SARS-COV-2 sources (in both time and space) with too much dilution and physical shear stress disruption to detect sufficient live virus that is reliably detectable by virus culture;

- We are mostly referring to the context of short-range aerosol transmission in the context of this review - so we should be air-sampling from within 1 m of the mouth and nose of infected cases - and most environmental sampling studies do not do this;

- It therefore follows that the negative virus viability with positive RNA findings in these environmental air-sampling studies does not exclude short-range aerosol transmission between people;

- And as air-sampling disrupts the vast majority of lipid-enveloped viruses during the quite violent sampling process - the lack of virus viability in these air-samples is not surprising;

If viable virus is present and detectable by conventional cell culture (as has been reported by some teams already) - in this context - this will also likely underestimate the number of viable viruses initially exhaled by an infectious source.

The comment on the virus viability in the hamster model needs to be better discussed. Infectious dose is not the same by different routes of transmission for many agents e.g. Influenza (Little *et al.* 1979, Couch *et al.* 1971, Alford *et al.* 1966). We note incidentally that aerosol transmission to hamsters and ferrets has been achieved in the laboratory (Port et al 2020, Kutter *et al.* 2021, Sia *et al.* 2020). We also note that any animal inoculation experiments (similar to the cell culture methods) attempted with air-sampled virus will also suffer from the above upstream air-sampling virus disruption problems.

So again, any absence of virus infection/viability seen in such animal models does not necessarily exclude airborne transmission of the virus.

Finally, on the authors' comment that PCR is “trivial”, we suggest that this comment indicates that none of the authors are practicing clinical virologists working in hospital diagnostician labs - otherwise they will be aware of the huge improvements to viral detection and management of viral infections that PCR has contributed to modern clinical medicine. It has been appreciated for many decades that laboratory diagnosis of viral infections by isolation in cell culture was very insensitive and relying solely on this technique was previously causing a lot of false negatives. Already in the 70s techniques of detection of viruses in clinical samples, for example respiratory viruses, by direct fluorescence microscopy was brought to bear to palliate the insensitivity of isolation in cell culture, and globally over the last 20 years, we have replaced most viral culture assays with PCR, on the basis this is a more sensitive method of detection, with less operator subjectivity. This includes routine virus PCR testing (without viral culture confirmation of viability) on:

- CSF (cerebrospinal fluid) - for HSV-1/2, VZV, EV, PeV, CMV, HIV, AdV, JCV, HHV6/7, etc. to diagnose, monitor and treat viral encephalitis - viruses do not culture easily from CSF and some of these viruses (HIV, JCV, HHV6/7) are difficult to grow in conventional cell culture.

- Blood for monitoring AdV, BKV, CMV and EBV viral loads (using quantitative PCR) checking for viral infection/reactivation post-organ transplant - these viruses are not reliably cultured or quantified from blood - as blood has many inhibitors of viral culture.

- Genital swabs for genital herpes infection (mostly from HSV 1-2) - where viral culture has been found to be less sensitive than PCR in multiple studies - so this risks missing earlier

lesions that could be treated earlier to reduce transmission to others, as well as for improved clinical outcomes for patients.

- Respiratory viruses - PCR has again proven much more sensitive - to detect RSV, parainfluenza, influenza, AdV, hMPV and multiple other seasonal respiratory viruses - not all of which grow easily in viral culture or are detected at low level by IF - again naso/oropharyngeal swabs can pick up inhibitors to viral culture.

In sum, we remain concerned that these authors may lack key expertise in their team and that as a result, their interpretation of the evidence and the conclusions they draw are potentially misleading and dangerous.

Author Response 11 Jun 2021

IGHO ONAKPOYA, University of Oxford, Oxford, UK

We would like to respond to the public comments by Prof. Jimenez and colleagues regarding our systematic review assessing the role of close contact in the transmission of SARS-CoV-2. We have itemized our responses respectively in line with each of the comments.

Response to comment #1. Thank you. We have found conflicting definitions of particle size and the issue of short vs long range transmission is complex and requires a common set of agreed upon definitions and more study.

Response to comment #2. As we make clear in the text, we draw no definitive conclusions on this issue. We do not "believe" anything without solid evidence.

Response to comment #3. We find this comment useful and propose close proximity (without physical contact) and close contact.

Response to comment #4. Once an agreed upon set of revised definitions is achieved, we and others would use them in any reviews of the evidence.

Response to comment #5. We do not conflate the two, hence the need for separate reviews.

Response to comment #6. The WHO guidance has not changed.

Response to comment #7. In our reviews we present and synthesize the original authors' findings

and have not ruled out any form of airborne transmission.

Response to comment #8. We are working on a method for identifying high quality evidence of transmission causality and testing it by applying it to our future reviews. (See: https://www.preprints.org/manuscript/202104.0633/v1)

Response to comment #9. We are happy to expand on the methods used to rate the reporting quality of the included studies.

Response to comment #10. PCR serves as a trivially simple and fast tool for detecting pathogens, but any virologist would tell you that the link between a nucleic acid signal and an infectious unit are complex and difficult to establish. There's lots of nucleic acid, some small fraction is packaged, and some yet smaller fraction of packaged viruses is infectious. Some aerosol publications assume that 1 nucleic acid signal = 1 infectious particle. This is wrong, in fact for SARS-CoV-2 the ratio is more typically >100,000 if one carefully calibrates the Ct values with internal standards Moreover, numerous studies have shown that while the PCR signal can persist for long periods of time, infectious virus are detected over a very narrow window of time, typically 7-10 days in otherwise immune competent individuals. (see Jefferson *et al*.) Ct values <25 are required to detect virus (from which one can calculate things like the RNA/PFU ratio).

The authors state that culturing viruses can be tricky. SARS-CoV-2 forms large distinctive plaques on a variety a cell lines, as long as they express the ACE2 receptor. Many different cell types have been tested, including cells designed to enhance the growth (e.g. TMPRSS2), all yield decent titers in the 10^6 to 10^ PFU/mL range. Similar titers are retrieved from the most infectious of patient specimens. Yes one needs BSL3 containment, but nowadays if one is looking for infectious SARS-CoV-2, there are no reasons not to grow it.

The interesting thing is that when one calculates the titer of virus in culture (TCID50) and measure the minimal infectious dose (MID) in the highly susceptible hamster model, the numbers are surprisingly congruent. The conclusion is that one plaque-forming unit in culture is one hamster infectious unit as well. If there's something wrong with using cell cultures to detect virus and measure titer, one would have to posit that the same exact problem characterizes the hamster model.

Reader Comment 31 May 2021

Jose-Luis Jimenez, University of Colorado-Boulder, Boulder, Colorado, USA

Public comment on Onakpoya *et al.* Review on Close Contact Transmission

We would like to offer some comments on the systematic review of Onakpoya *et al.* on close contact transmission of COVID-19.

First, we commend the authors for using the F1000 platform that allows posting of public comments from any scientist during peer review. This allows interested scientists to bring up issues and evidence that may not have been considered by the authors, and thus more cross-pollination than would be possible with traditional anonymous closed peer-review.

However, there are some major problems with the choice of the topic as "close contact transmission," and the framing and description of the topic by Onakpoya *et al*.

1) The other reviews by this group concern airborne, orofecal, and fomite transmission, all of which are actual transmission mechanisms. However, **"close contact" is a measurement of distance, not a mechanism of transmission.**

The authors acknowledge this when they state, "The mechanistic pathway for transmission in close contact settings is unclear", and also mention, "there is lack of clarity about how research should be conducted in the setting of transmission with close contact which may include transmission via any one of or the combination of respiratory droplets, direct contact, or indirect contact."

However, short-range airborne transmission is never mentioned, even though recent results indicate that it is the **dominant** transmission mechanism between talking individuals, and is also important when coughing (Chen *et al.* 2020). Talking in close proximity is important for pre-symptomatic, asymptomatic, and mildly-symptomatic (PAMS) individuals, which are important contributors to transmission in this pandemic (Johansson *et al.* 2021; Jones *et al.* 2021). For clarity, short-range airborne transmission is the inhalation of respiratory aerosols while in close proximity (Chen *et al.* 2020; Li 2021; Milton 2020). Those are the same respiratory aerosols that can cause

infection at larger distances when dispersed in shared room air, a mechanism that can explain most superspreading events (Miller *et al.* 2021; Greenhalgh *et al.* 2021a).

Aerosols are much more concentrated in exhaled breath from an infectious person than in room air. Thus, for **airborne diseases that can infect through shared room air despite large dilution, they would naturally be much more infectious in close proximity** (Tang *et al*. 2021a; Tang *et al.* 2021b).

In the revision of this paper, the authors must acknowledge the recent scientific literature, including the likelihood that "close contact" transmission is actually dominated by short-range airborne transmission.

2) Equally important, are the authors preparing a systematic review on large droplet transmission of SARS-CoV-2? That is the mechanism that WHO and some of the co-authors of this systematic review have upheld as dominant throughout much of the pandemic (Conly *et al.* 2020; World Health Organization 2020). Thus, **it would behove the authors to synthesize the presumably strong evidence that large droplets are actually important for transmission**. If they are indeed so important, it should not be hard to compile strong and abundant evidence?

A recent review of the literature by Prof. Yuguo Li (a current member of the WHO IPC R&D committee (World Health Organization 2021b)) and colleagues concludes that, "reviewing the literature of large droplet transmission, one can find no direct evidence for large droplets as the route of transmission of any disease" (Chen *et al.* 2020). If Onakpoya *et al.* disagree, and believe that droplet transmission has been **directly** demonstrated for any disease, we would appreciate the addition of key references in their response.

As we discuss below, equating ease of infection in close proximity with droplet transmission is a major conceptual error that has prevailed for over a century.

3) The term "close contact" is also ambiguous, since the word "contact" is used, implying direct physical contact. However, any situation in close proximity may be described as "close contact," whether physical contact actually occurred or not. We would like to suggest **"close proximity" as a clearer term for future use.**

4) **A pervasive error in the field of disease transmission has been equating "close contact transmission" with large droplet, direct contact, and fomite transmission only, and excluding airborne transmission**. It is important to correct this error, and to recognize that transmission in close proximity is likely dominated by short-range airborne transmission, via aerosol inhalation (Chen *et al.* 2020).

The error conflating ease of infection in close proximity with droplet transmission dates from the work of Dr. Charles Chapin in 1910. Dr. Chapin conceptualized contact infection in his seminal book, "The sources and modes of infection" (Chapin 1912). He realized that ease of infection in close proximity could be explained by large droplets that fell to the ground close to the infected person, a mechanism that he referred to as "spray-borne" transmission, or by inhalation of smaller particles (now commonly referred to as aerosols) through airborne transmission. Despite lacking

evidence, he expressed his opinion that spray-borne infection was dominant in close proximity and airborne infection was unlikely to be important: "It will be a great relief to most persons to be freed from the specter of infected air, a specter which has pursued the race from the time of Hippocrates." This was due partly to his desire to win acceptance for the concept of contact infection, which he considered the most important mode of infection, since (in his words), "it is impossible, as I know from experience, to teach people to avoid contact infection while they are firmly convinced that the air is the chief vehicle of infection" (Chapin 1912).

This conflation of ease of infection in close proximity with large droplets became widely accepted, despite the (continuing) lack of evidence to support it (Chen *et al.* 2020). It has become a dogma in this field for over a century (Randall *et al.* 2021). Supporting evidence has often been attributed to the work of Carl Flugge, and large droplets are referred to as "Flugge's droplets." Although only visible spray-borne droplets had been considered for disease transmission by some earlier researchers (Cornet 1889), Flugge and coworkers in the 1890s used the term "droplets" to refer to both droplets and aerosols. In their experiments, they often waited up to 5 hours to allow settling of smaller aerosols onto their collection plates (Randall *et al.* 2021; Chapin 1912).

5) **The same error of conflating ease of infection in close proximity with large droplet transmission was used to designate measles as a droplet/fomite disease until about 1985** (Bloch *et al.* 1985). It is now clear that much, or all, of the close proximity transmission of measles that had been attributed to droplets is indeed short-range airborne transmission. There is no fundamental reason why this error cannot apply to other diseases. Tuberculosis is also most easily acquired in close proximity, yet it can only be transmitted through the airborne mechanism (Sepkowitz 1996). Ease of transmission in close proximity is also observed for chickenpox, another well-known airborne pathogen (CDC 2021a).

6) The statement by Onakpoya *et al*. that, "Current evidence from epidemiologic and virologic studies suggest SARS-CoV-2 is primarily transmitted via respiratory droplets and direct and indirect contact", **is now outdated, outmoded and frankly, dangerous**.

Both the WHO (World Health Organization 2021a) and the US CDC (CDC 2021b) have recently accepted that airborne transmission is an important form of transmission for SARS-CoV-2. This follows overwhelming scientific evidence that has accumulated in support of airborne transmission, which many scientists now consider the predominant mode of transmission of SARS-CoV-2 (Greenhalgh *et al.* 2021a). We now have a broader understanding of the long-standing errors and misinterpretations about airborne transmission that led to it being underappreciated for many diseases (Tang *et al.* 2021a; Tang *et al.* 2021b; Randall *et al.* 2021; Chen *et al.* 2020; Greenhalgh *et al.* 2021a; Greenhalgh, *et al.* 2021b).

7) The authors note that, "Enclosed environments and social gatherings appear to increase the likelihood of close contact transmission." This can be explained by short-range airborne transmission, due to greatly reduced dispersion of aerosols in inadequately ventilated indoor environments. Typical air speeds outdoors are at least 10 times larger than indoors. However, increased indoor transmission cannot be easily explained by large droplets since gravity is the same indoors and outdoors. **If the authors have a mechanistic explanation of how enclosed environments would increase transmission, in the absence of airborne transmission, it**

should be presented in the review.

8) Onakpoya *et al.* state, in support of close contact transmission, "Our review [...] shows evidence demonstrating positive culture of virus as well as genomic evidence of close contact transmission. This differs from the findings from our reviews of fomite, orofecal and airborne transmission that failed to show evidence of either positive culture or genomic sequences demonstrating SARS-CoV-2 transmission."

We thus expected to find studies where the virus had been cultivated from samples of large droplets or samples taken from e.g. hands. However, the two cited studies with positive viral culture performed the culture analyses of nasal swabs (Ladhani *et al.* 2020) and of, "throat swab and bilateral nasopharyngeal or deep nasal specimens" (Speake *et al.* 2020). **It is a logical error to associate the presence of cultivable virus from clinical specimens taken from an infected person with 'close contact transmission'** (especially as narrowly defined here, excluding short-range airborne transmission) and not with other forms of transmission. Similarly one may find cultivable tuberculosis, measles, and chickenpox pathogens from clinical specimens, but that does not mean that transmission in close proximity is explained by large droplets or direct or indirect contact. The most likely (measles, chickenpox) or only (tuberculosis) mechanism of transmission of those diseases in close proximity will be short-range airborne transmission. Therefore the erroneous association of positive cultures of nasal swabs as supporting a narrow definition of close contact transmission needs to be removed.

9) We question the use of the "modified" QUADAS 2 risk of bias tool as the sole arbiter of quality in the primary studies analyzed for this review. QUADAS 2 was designed for diagnostic accuracy studies in which a new test is compared with an existing gold standard in a representative sample of participants (Whiting *et al.* 2011). It is essentially an epidemiological tool whose purpose is to ensure that the sample was representative and the 'gold standard' comparator is a legitimate gold standard for the disease or risk state in question. The 'biases' it identifies relate to such things as sampling of participants (e.g. do the patients in the study accurately represent the range of patients with the target condition?), sample size, completeness of follow-up and so on. **QUADAS 2 was not designed to assess essential aspects of quality in laboratory studies**. Extraordinarily, the authors do not even state how they modified the QUADAS 2 tool and they certainly make no attempt to justify or defend this modification. We question, therefore, whether the process adopted for assigning studies to "low", "medium" or "high" quality is valid. At a minimum, the fitness of purpose as well as the modifications of the QUADAS2 tool need to be described in detail and justified in the revised version of this paper.

10) Using *in vitro* viral culture as the gold standard to define the potential for virus transmissibility between humans is not a sensitive approach. Indeed, many clinical viral infections are treated on the basis of PCR results alone. Viral culture is not a sensitive method to detect viruses - it has never been (van Elden *et al.* 2002). It is one of the 'catch-all' methods used in virology to identify the presence and amplify new viruses - like electron-microscopy - both of which need hundreds to thousands of viruses to enable detection and identification. For cell culture also, one needs to identify the optimal cell-line and this differs between viruses. The authors are already off to a bad start when they are proposing viral culture as the 'gold standard' of detection for any virus - especially respiratory viruses when there are multiple cell-line options for culturing them - as they

then need to define which ones should be used as the 'gold standard' for each virus and there is not always just one option for this.

Virologists know that just one virus of any species will not necessarily culture successfully in any cell culture system - you need a minimum viral load to be successful in viral culture, which can vary between viruses and cell-lines. So if it cultures, then that is a positive result (assuming no lab contamination has occurred), but if not, it does not mean that there is no infective virus present. Different viral species and variants have different tropisms and therefore different degrees of success in growing in different cell-lines under different conditions.

Assigning 'gold standard' criteria for viral culture as proof of viral transmission is neither sensitive (it can give false negative results), **nor reliable** (it may not be always reproducible), **nor robust** (too many factors, including the way that the sample was collected and stored, can significantly perturb this process). Suggesting that serial culture is needed in a 'gold standard' deepens the problems even more.

David Tomlinson , University Hospitals Plymouth NHS Trust, Plymouth, UK

Dear Dr Onakpoya and team,

Thank you for posting your article *'SARS-CoV-2 and the role of close contact in transmission: a systematic review [version 1; peer review: awaiting peer review]'* on the F1000Research site and for inviting comments. I hope you find the following comments to be constructive, free from bias and useful towards improving your manuscript.

Introduction

'Current evidence from epidemiologic and virologic studies suggest SARS-CoV-2 is primarily transmitted via respiratory droplets and direct and indirect contact[2,3.]'

Ref 2: 'World Health Organization: Modes of transmission of virus causing COVID-19: implications for IPC precaution recommendations. [Accessed 16/01/2021]' links to WHO 'Modes of transmission of virus causing COVID-19: implications for IPC precaution recommendations, Scientific brief, 29 March 2020.' Ref 3: 'World Health Organization: Coronavirus disease 2019 (COVID-19) Situation Report – 73. [Accessed 28 February 2021]' link does not work.

On 5th April 2021 and in updated guidance the CDC stated: "Findings of these studies suggest that the risk of SARS-CoV-2 infection via the fomite transmission route is low, and generally less than 1 in 10,000, which means that each contact with a contaminated surface has less than a 1 in 10,000 chance of causing an infection.". Furthermore, since the latest WHO IPC Scientific Brief, July 2020, much more evidence towards the dominant role for airborne transmission of SARS-CoV-2 has been identified: investigations supporting this proposition include the recovery of live virus from the air, animal transmission studies using models excluding fomite and/or droplet routes, and detailed epidemiological investigations into transmission events possible only via the airborne (short and long-range) route. Greenhalgh T *et al.* (2021) recently reviewed and described these lines of evidence, concluding: 'There is consistent, strong evidence that SARS-CoV-2 spreads by airborne transmission. Although other routes can contribute, we believe that the airborne route is likely to be dominant.'.

Therefore, I would be grateful if the authors would change this sentence to reflect these most recently available data, please. Thank you.

Box 1: terminology.

Re: *'Close contact: Someone who was within 6 feet of an infected person for a cumulative total of 15 minutes or more over a 24-hour period starting from 2 days before illness onset (or, for asymptomatic patients, 2 days prior to test specimen collection) until the time the patient is isolated;1 The World Health Organization (WHO) additionally includes direct physical contact with a probable or confirmed case, direct care for a patient with probable or confirmed COVID-19 disease without using proper personal protective equipment, and other situations as indicated by local risk assessments.'*

The link provided is for a CDC site titled: 'Operational Considerations for Adapting a Contact Tracing Program to Respond to the COVID-19 Pandemic in non-US Settings' . The text used at this CDC site is an almost identical to that used in this present manuscript: 'Close contact is defined by CDC as

someone who was within 2 meters of an infected person for at least 15 minutes within a 24-hour period starting from 2 days before illness onset (or, for asymptomatic cases 2 days prior to positive specimen collection) until the time the patient is isolated. The World Health Organization (WHO) additionally includes persons with direct physical contact with a probable or confirmed case, direct care for a patient with probable or confirmed COVID-19 disease without using proper personal protective equipment, and other situations as indicated by local risk assessments.'

Given the similarity in wording and the fact that the WHO is mentioned as appropriate by the authors, I would be grateful if the authors could include reference to this being the CDC definition as appropriate, please. Also, omission of the word 'positive' in this sentence is in error and should be corrected please: *'2 days prior to test specimen collection'*. Thank you.

Re: *'Attack rate: The proportion of those who become ill after a specified exposure[2].'*
This link is blocked. When I typed link 2 web address in directly, I reached a WHO webpage stating: "This page cannot be found. The page or file you are trying to access cannot be found. This is because the web address is incorrect or the file has been moved or deleted. In 2020, we migrated our web content to a new system so some older content may no longer be available online or at the same place."

I would be grateful if the authors would correct this please. Thank you.

Re: *'Secondary attack rate: The probability that infection occurs among susceptible persons within a reasonable incubation period following known contact with an infectious person or an infectious source[3].'*

The reference given is a textbook which cannot be readily accessed. Furthermore, the wording 'within a reasonable incubation period' seems insufficiently exact: given that this manuscript is only focused on the assessment of a single pathogen, could the authors provide a more appropriate and reproducible definition of a time interval for SARS-CoV-2 secondary attack rate, please? Thank you.

Methods

Re: *'published protocol last updated on the 1 December 2020 (Version 3: 1 December 2020, Extended data: Appendix 1[6])'*

This Appendix document (*'Web Appendix 1'*) states: *'For the respective topics we used the following terms:*

Airborne: aerosol OR airborne OR airbourne OR inhalation OR air OR droplet
Orofecal: orofecal OR oro-fecal OR faecal OR fecal OR stool OR faeces OR feces OR rectal OR rectum OR anal OR anus OR toilet
Fomite: fomite OR surfaces

These terms were also combined with the term transmission.'

The search terms for the present topic 'close contact' are not listed here. Please could the authors provide a complete list of search terms employed for this present manuscript? Thank you.

Web Appendix 1 states: *'Objectives*
Objectives are to provide a rapid summary and evaluation of relevant data on transmission of SARS-CoV-2, report important policy implications, and highlight areas of research urgently needed. These transmission areas include airborne, contact and droplet, orofecal, vertical, fomite and other modes such as urine and blood and body fluids.'

The 'transmission area' of 'close contact' is not listed here. Could the authors please explain why? Thank you.

Re: *'We assessed the risk of bias of included primary studies using five domains from the QUADAS-2 criteria[7]; we adapted this tool because the included studies were not primarily designed as diagnostic accuracy studies.'*

The QUADAS-2 tool is for 'more transparent rating of bias and applicability of primary diagnostic accuracy studies'. The authors state that they *'adapted this tool'* and yet you no description of the adaptation methods is provided. Accordingly, these methods are neither transparent, nor reproducible – a contradiction to the stated intent of the authors who developed the QUADAS-2 tool. Please could the authors explain how this tool was adapted for this present manuscript, in terms allowing an assessment of its methodological validity? Thank you.

Finally, I hope the authors don't mind me providing a more general comment? I have concerns regarding the stated aim towards performing a systematic review of the possible 'role of close contact' in [SARS-CoV-2] transmission. The authors will of course be aware that 'Close contact' is a new classification when considering presently accepted modes of transmission. For example, the terminology below is endorsed by the CDC:

"An infectious agent may be transmitted from its natural reservoir to a susceptible host in different ways. There are different classifications for modes of transmission. Here is one classification:

Direct

- Direct contact
- Droplet spread

Indirect

- Airborne
- Vehicle-borne
- Vector-borne (mechanical or biologic)'

Source: Principles of Epidemiology in Public Health Practice, Third Edition, An Introduction to Applied Epidemiology and Biostatistics.

Furthermore, the scientific basis for the definition of 'close contact' is without suitable validation, since the stated source for this definition is a document titled: 'Operational Considerations for Adapting a Contact Tracing Program to Respond to the COVID-19 Pandemic in non-US Settings.' Clearly, this 'operational' manuscript does not prove the independent benefit or validity of a new 'close contact' nomenclature towards describing the transmission of an infectious disease.

Therefore, I believe it is important for the authors to explain how and why they came to derive this novel terminology, including a description of its scientific basis with an explanation of how the authors believe it to be a necessary introduction to infectious diseases terminology in addition to the presently accepted and objectively defined modes of transmission. Thank you.

I hope the authors will understand that from my comments above, it is my assertion that the methods employed in this present manuscript are so importantly flawed and/or inadequately described, that neither the results nor conclusions of this present manuscript can be considered to be scientifically valid.

I would once more like to thank the authors for providing the opportunity for comments to be made in response to this present manuscript. I genuinely admire this approach: a research team willing to declare manuscripts open to peer review, and also hopefully open to the possibility that comments received may help towards improving the quality of their final published work.

Competing Interests: I have no conflicts of interest.
