ABSTRACT

Background

Radiotherapy and chemotherapy are used to improve survival in colorectal cancer but adverse effects can be a problem. Severe adverse effects may result in dose reduction or cessation of treatment, which have an impact on survival. *Coriolus versicolor* (*Trametes versicolor* or 'Turkey Tail') mushroom and its extracts have been used by cancer patients to help with adverse effects.

Objectives

To assess the effects of adjunctive *Coriolus versicolor* (*Trametes versicolor*) and its extracts on adverse effects and on survival during colorectal cancer treatment (chemotherapy and radiotherapy) compared with no adjunctive treatment.

Search methods

We searched databases including CENTRAL, MEDLINE, Embase, AMED and CINAHL, Chinese and Japanese databases, and trials registers to 12th April 2022 without restriction of language or publication status. We screened reference lists and attempted to contact researchers in the field to identify additional studies.

Selection criteria

We included randomised controlled trials (RCTs) investigating the efficacy and safety of *Coriolus versicolor* and its extracts in adult participants with a confirmed diagnosis of colorectal cancer, in addition to conventional treatment. Interventions included any preparation of *Coriolus versicolor* (raw, decoction, capsule, tablet, tincture, extract, injection), any part of the fungus (cap, stem, mycelium or whole), in any dose or regimen. Outcomes included adverse events rates, survival, disease progression and recurrence, response rates and quality of life.

Data collection and analysis

Two review authors independently screened and selected studies, extracted outcome data, and assessed risk of bias. We evaluated the overall certainty of evidence using the GRADE approach.

Main results

We included seven parallel RCTs (1569 participants). Six studies (1516 participants) were conducted in Japan and one study (53 participants) in China. Studies included both male and female participants with colorectal cancer (five studies), colon cancer (one study)

***Coriolus (Trametes) versicolor* mushroom to reduce adverse effects from chemotherapy or radiotherapy in people with colorectal cancer (Review)**

1

or rectal cancer (one study). Participants were diagnosed with cancer ranging from stage II to stage IV. *Coriolus* was used in the form of an extract in all seven studies and was generally used after curative resection, although in one study it was used preoperatively. Duration of treatment with the extract varied between four weeks and three years. Chemotherapeutic regimens in six studies consisted of an oral fluoropyrimidine which was preceded by weekly intravenous 5-Fluorouracil (5-FU) in one study, by mitomycin C in two studies, and which was combined with folinic acid (Leucovorin) in two studies and with radiotherapy preoperatively in one study. XELOX (oxaliplatin intravenous infusion and capecitabine) was used in the remaining study.

We found very low-certainty evidence of little to no effect of adjunctive treatment with *Coriolus* (in the form of an extract, polysaccharide-Krestin, PSK) on withdrawal from treatment due to adverse events (risk ratio (RR) 1.03, 95% confidence interval (CI) 0.45 to 2.34; 703 participants; 3 studies;). We are uncertain whether adjunctive *Coriolus versicolor* and its extracts compared to usual care alone resulted in a difference in adverse events including neutropenia (RR 0.41, 95% CI 0.24 to 0.71; 133 participants; 3 studies; very low certainty), oral cavity disorders such as oral dryness and mucositis (RR 0.37, 95% CI 0.13 to 1.03; 1022 participants; 5 studies; very low certainty), nausea (RR 0.73, 95% CI 0.44 to 1.22; 969 participants; 4 studies; very low certainty), diarrhoea (RR 0.77, 95% CI 0.32 to 1.86; 1022 participants; 5 studies; very low certainty), and fatigue (RR 0.76; 95% CI 0.33 to 1.78; 133 participants; 3 studies; very low certainty).

We found low-certainty evidence of a small effect of adjunctive *Coriolus* on improved survival at five years compared with no adjunctive care (RR 1.08, 95% CI 1.01 to 1.15; 1094 participants; 3 studies; number needed to benefit (NNTB) = 16 (95% CI 9 to 70). The effect at earlier time points was unclear.

Authors' conclusions

Due to the very low certainty of evidence, we were uncertain about the effect of adjunctive *Coriolus* (in the form of an extract PSK) on adverse events resulting from conventional chemotherapy for colorectal cancer. This includes effects on withdrawal of treatment due to adverse events and on specific adverse outcomes such as neutropenia and nausea. The uncertainty in the evidence also means that it was unclear whether any adverse events were due to the chemotherapy or to the extract itself. While there was low-certainty evidence of a small effect on overall survival at five years, the influence of reduced adverse effects on this could not be determined. In addition, chemotherapy regimens used in assessing this outcome do not reflect current preferred practice.

PLAIN LANGUAGE SUMMARY

Coriolus versicolor mushroom in colorectal cancer

Review question

Does adding *Coriolus* to colorectal (bowel) cancer treatment reduce side effects and improve survival?

Background

Radiotherapy and chemotherapy are used to treat colorectal cancer but side effects can be a problem. *Coriolus versicolor* mushroom (also known as *Trametes versicolor* or 'Turkey Tail') and its extracts have been used by cancer patients to help with side effects.

Search date

We searched medical databases for trials comparing *Coriolus* plus chemotherapy or radiotherapy to chemotherapy or radiotherapy alone in adults (aged 18 years or greater). The evidence is current to April 2022.

Study characteristics

We included seven trials with 1569 participants who were men and women with stage 2 to 4 cancer. Six studies were carried out in Japan and one study was carried out in China. Studies measured changes in survival, frequency of side effects and changes to treatment due to side effects. One study reported on quality of life. All studies used an extract of *Coriolus* known as Polysaccharide-Krestin (PSK).

Study funding sources

No study reported any information on funding.

Key results

We found that it was unclear if adding *Coriolus* made any difference to the number of patients whose treatment had to be stopped because of side effects.

We found that the evidence was also uncertain about whether adding *Coriolus* to treatment reduced side effects caused by chemotherapy or radiotherapy. We looked at evidence for a range of different side effects including effects on blood tests, and problems such as inflammation of the mouth, nausea and diarrhoea.

We found low-certainty evidence of a small effect of adding *Coriolus* on survival at five years compared with no added *Coriolus*. Effects before five years were not clear. Cancer stages varied as did cancer treatment. Patients in some studies were being treated with combinations of cancer drugs that are not widely used in practice now and most of the studies were carried out some time ago.

Certainty of the evidence

Participants in all the studies were aware of whether they had been treated with *Coriolus* and this may have influenced their reporting of changes in nausea and other self-reported problems. It should not have made any difference to laboratory tests such as blood tests. Some of the methods reported in studies were unclear and few patients were included in many of the comparisons that we examined. We found that the evidence was either low or very low certainty for all comparisons.

SUMMARY OF FINDINGS
Summary of findings 1. Adjunctive Coriolus versicolor compared to no adjunctive treatment for colorectal cancer treatment
Adjunctive Coriolus versicolor compared to no adjunctive treatment for colorectal cancer treatment
Patient or population: adults (aged 18+) with colorectal cancer

Setting: hospital outpatient

Intervention: Coriolus versicolor adjunctive to chemotherapy

Comparison: chemotherapy without adjunctive treatment

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Nº of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with no adjunctive treatment	Risk with Adjunctive Coriolus versicolor				
Survival - Follow-up: 5 years	Study population		RR 1.08 (1.01 to 1.15)	1094 (3 RCTs)	⊕⊕⊕⊕ LOW ¹	May be a small improvement in survival with PSK at 5 years but not relevant to current therapy and, thus, unclear whether any advantage currently
	746 per 1,000	806 per 1,000 (754 to 858)				
Withdrawal from treatment due to adverse events - Follow-up 6 months to 5 years	Study population		RR 1.03 (0.45 to 2.34)	703 (3 RCTs)	⊕⊕⊕⊕ VERY LOW ²	Uncertain whether there is a difference
	32 per 1,000	32 per 1,000 (14 to 74)				
Adverse events: Oral cavity disorders (includes oral dryness and mucositis)- Follow-up 6 months to 7 years	Study population		RR 0.37 (0.13 to 1.03)	1022 (5 RCTs)	⊕⊕⊕⊕ VERY LOW ³	Uncertain whether there is a difference
	29 per 1,000	11 per 1,000 (4 to 30)				
Adverse events: Nausea - Follow-up 4 weeks to 7 years	Study population		RR 0.73 (0.44 to 1.22)	969 (4 RCTs)	⊕⊕⊕⊕ VERY LOW ⁴	Uncertain whether there is a difference
	66 per 1,000	48 per 1,000 (29 to 80)				
Adverse events: Diarrhoea - Follow-up 4 weeks to 7 years	Study population		RR 0.77 (0.32 to 1.86)	1022 (5 RCTs)	⊕⊕⊕⊕ VERY LOW ⁴	Uncertain whether there is a difference
	80 per 1,000	61 per 1,000 (26 to 148)				

Adverse events: Neutrophils decreased - Follow-up 4 weeks to 3 years	Study population		RR 0.41 (0.24 to 0.71)	133 (3 RCTs)	⊕⊕⊕⊕ VERY LOW ⁵	Uncertain whether there is a difference
	364 per 1,000	149 per 1,000 (87 to 258)				
Adverse events: Fatigue - Follow-up 4 weeks to 3 years	Study population		RR 0.76 (0.33 to 1.78)	133 (3 RCTs)	⊕⊕⊕⊕ VERY LOW 4	Uncertain whether there is a difference
	227 per 1,000	173 per 1,000 (75 to 405)				

***The risk in the intervention group** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: Confidence interval; **RR:** Risk ratio; **OR:** Odds ratio;

GRADE Working Group grades of evidence

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect.

¹ Downgraded one level for indirectness as the chemotherapy regimens include those not reflecting current preferred practice and one level for imprecision as the total number of events was less than 300.

² Downgraded one level for indirectness as the chemotherapy regimens include those not reflecting current preferred practice, one level for risk of performance and detection bias, and two levels for imprecision as the total number of events is less than 300 and the CI includes both no effect and an important effect.

³ Downgraded one level for indirectness as the chemotherapy regimens include those not reflecting current preferred practice, one level for risk of selection, performance and detection bias, and one level for imprecision as the total number of events is less than 300.

⁴ Downgraded one level for indirectness as the chemotherapy regimens include those not reflecting current preferred practice, one level for risk of selection, performance and detection bias, and two levels for imprecision as the total number of events is less than 300 and the CI includes both no effect and an important effect.

⁵ Downgraded one level for indirectness as the chemotherapy regimens include those not reflecting current preferred practice, one level for risk of selection, performance, detection and attrition bias, and one level for imprecision as the total number of events is less than 300.

BACKGROUND

Description of the condition

Approximately 19.3 million new cases of cancer were diagnosed worldwide in 2020 (Sung 2021), increasing from 18.1 million in 2018 (Bray 2018a). Colorectal cancer is the third most common cancer, with an increasing incidence in the developing world (Bray 2018b). Colorectal cancer includes colon (large bowel) cancer and cancer of the rectum (the last portion of the gastro-intestinal tract before the anus). It may result in blood in the stools and anaemia, and gastro-intestinal symptoms including change in bowel habit and abdominal pain (Astin 2011). The treatment of colorectal cancer may involve surgery, systemic anti-cancer therapy (chemotherapy and targeted monoclonal antibodies designed to target specific types of cells) or radiotherapy (ESMO 2014; ASCO 2020). Both the disease and its treatment may cause symptoms such as fatigue, anorexia, or depression, which adversely affect the quality of life of patients with colorectal cancer (Gray 2011). Chemotherapy regimens incorporating oxaliplatin or irinotecan, or both, may be more effective at preventing recurrence or delaying disease progression than those based solely on 5-fluorouracil/leucovorin, but serious adverse events and discontinuation of treatment due to toxicity are more frequent (André 2004; Pandor 2006; Schmoll 2007). Treatment-related adverse effects, including diarrhoea, neutropenia (low levels of neutrophils), stomatitis (inflammation of the mouth), nausea and vomiting, peripheral neuropathy (nerve damage), and hand-foot syndrome are commonly reported and toxicity may be severe in up to 57% of patients (Grothey 2018), requiring dose reduction or withdrawal of potentially life-saving or life-prolonging treatment. Thus, there is a need for adjunctive therapies that can support colorectal cancer patients through conventional cancer therapy by alleviating symptoms and side effects without adversely affecting overall survival.

Description of the intervention

Mushrooms have a long history of use to promote health in China and Japan and, as some mushroom preparations are orally bioavailable, they are relatively easy to administer (Lindequist 2005). Medicinal mushrooms appear to have low toxicity and immune-modulating and health-promoting properties have been reported based on pre-clinical studies (Jeitler 2020). Numerous studies have also been conducted in humans and several mushroom extracts are licensed as adjunctive treatments in oncology practice in Japan (Kidd 2000; NCI 2022). There has been increasing interest in Western countries in the reported health benefits of various mushrooms (Venturella 2021), and specifically in whether there is a potential role in oncology (Jeitler 2020; Standish 2008). The four mushrooms commonly used clinically are *Coriolus versicolor* (*C. versicolor*) (also known as *Trametes versicolor*, Japanese and Chinese names *Kawaratake* and *Yun Zhi*, respectively), *Ganoderma lucidum* (Reishi or Ling Zhi), *Lentinula edodes* (Shiitake or Hua Gu/Xiang Gu) and *Grifola frondosa* (Maitake or Hui Shu Hua) (Smith 2002; NCI 2022).

The 'Turkey Tail' fungus (*Coriolus versicolor* (L.) Quél or *Trametes versicolor* (L.) Lloyd), the focus of this review, has a colourful fruiting body with features that resemble a 'turkey tail' (Smith 2002). It grows on dead logs in many countries worldwide and is not edible. Hot-water extracts of the whole fruiting body have been used in traditional Chinese medicine since historic times (Smith 2002). Two commercial extracts have been used clinically in the

Far East: polysaccharide-Krestin (PSK) and polysaccharopeptide (polysaccharide-peptide or PSP) (NCI 2022). Both are orally bioavailable extracts from the cultured mycelium (the filamentous part of the mushroom that grows through the soil) of the *Coriolus versicolor* fungus. PSK (or Krestin®) was developed in Japan in the 1960s and is a soluble protein-bound polysaccharide derived from the CM-101 strain of the fungus (Wan 2013). Production of Krestin was discontinued in Japan from September 2017 (Daiichi Sankyo 2017), but similar products are still available. PSP was developed in China in the 1980s and is a polysaccharide-peptide derived from the COV-1 strain (Kidd 2000; Smith 2002). The molecular weights of the two preparations (about 100 kDa) and the biochemical compositions are similar, but not identical. Commercial cultivation and production aims to ensure a steady supply of the fungus, control of the polysaccharide concentration (which varies considerably in the plant depending on growth phase and storage conditions), and purity of the final product. Many products derived or extracted from *Coriolus* are available online, however, over-the-counter products may not be standardised (Memorial Sloan-Kettering 2022).

Coriolus extracts are used as adjunctive therapy for treating cancers, either combined with herbal mixtures in Asian cultures, or combined with conventional chemotherapy/radiotherapy, and they have been reported to have an effect by boosting suppressed immune function, extending the survival rate and improving quality of life (Eliza 2012).

Recommended doses vary according to the preparation. In the Chinese Pharmacopoeia, the recommended dose of *Coriolus versicolor* is 9 g to 27 g used for decoction daily (Chinese Pharmacopoeia 2015 and Chinese Pharmacopoeia 2020) The daily dose of the authorised PSK product (Krestin®), according to the manufacturer, is 3 g (Daiichi-Sankyo 2012). Doses of PSK most commonly used in clinical trials in cancer have been between 1 g and 3.6 g daily (Eliza 2012). Data available on pharmacokinetics are based mainly on studies in animal (small mammal) models. These indicate that PSK is rapidly absorbed and partly metabolised in the gastro-intestinal tract. Peak plasma levels occur between 0.5 to 2 hours for small molecules and 4 to 24 hours for large molecules (Ikuzawa 1988). Excretion is primarily through the lungs with 70% excreted in expired air after 24 hours (Daiichi-Sankyo 2012; Ikuzawa 1988). Radiolabelled PSK or its metabolites are also excreted in the urine and faeces with 86% excreted within 24 hours (Ikuzawa 1988). Adverse interactions between *Coriolus versicolor* mushroom and herbs or drugs have not been reported except for a potential interaction with cyclophosphamide (Natural Database 2022). PSP has been shown to affect phase I metabolism and hepatic cytochrome P450 in animal models, but the potential for clinically significant interactions in humans is low (Yeung 2012).

How the intervention might work

Coriolus versicolor has been used in traditional Chinese medicine as a general 'tonic' for anorexia, fatigue, and lack of strength (Chinese Pharmacopoeia 2015 and Chinese Pharmacopoeia 2020). It was recorded as an 'immune modulator' in the 2005 Chinese Pharmacopoeia (Chinese Pharmacopoeia 2005) although not in the more recent editions. The pharmacological actions of mushrooms have been studied extensively in Japan and China in animal and human studies (Rowan 2003; Sullivan 2006; Venturella 2021). These studies support the idea that they are biological response modifiers that act by stimulating the non-specific

immune system (Lindequist 2005; Ng 1998). Immune activating properties of both mycelium and its fermented substrate have been demonstrated in vitro (Benson 2019).

PSK has been shown to restore immune systems depressed by chemotherapy to normal levels in animal studies, and has been reported to improve survival in clinical studies (Sakamoto 2006). PSK is also reported to attenuate the adverse reactions induced by chemotherapy or radiotherapy, including neutropenia (Maehara 2012). Similar effects are reported for PSP: results of clinical trials in China indicated reduction in chemotherapy-induced adverse effects, including vomiting, and restoration of chemotherapy-induced immunosuppression when PSP was used in combination with cytotoxic agents (Chan 2006). Such findings suggest that these extracts have the potential to improve tolerance to chemotherapy and radiotherapy and to reduce adverse effects due to depressed immune function. Both products also appear to have anti-tumour properties, which may contribute to an overall effect on survival (Eliza 2012).

The mechanism of action is yet to be fully established. The immune-potentiating activity is attributed to mushroom proteoglycans: these proteoglycans comprise a central linear polypeptide chain with multiple side-branches of beta-D-glucans (Kidd 2000). Multiple potential actions have been reported including suppression of tumour cell growth, reversal of immune suppression, and an increase in white blood cell counts, mediated in part by scavenging of free radicals by PSK (Fisher 2002). Reviews of the biological effects of PSK suggest that it has beneficial effects on cytokines ('chemical messengers') including tumour necrosis factor-alpha (TNF α), interferon-gamma (IFN γ), and interleukin-2 (IL-2) (Standish 2008). Animal studies indicate that PSK does not affect the normally functioning immune response but can contribute to the restoration of a response depressed by tumour burden or chemotherapy. Specific mechanisms of extracts of *Coriolus* considered to be involved include production of antibodies and cytokines, and improved activity of natural killer cells, T cells, macrophages, and peripheral blood lymphocytes (Chang 2017).

While immune-stimulatory actions may contribute to the apparent beneficial effects of these extracts, the mechanism of action underlying reports of reduced adverse effects when these extracts are used in combination with anticancer agents is as yet unclear. Effects on the pharmacokinetics of cytotoxic agents have been observed in some animal studies but results from human studies indicate that clinically significant effects are unlikely (Chan 2006).

Why it is important to do this review

For colorectal cancer patients in particular, radiotherapy and chemotherapy are used to improve survival, but side effects can be a problem with significant numbers of patients suffering severe effects, resulting in dose reduction or cessation of treatment, which have an impact on survival (Grothey 2018; Roeder 2020). Some of these side effects, such as fatigue and peripheral neuropathy, can persist into the survivorship period (Han 2020) and, as more cancer patients survive, the prevalence of those with persistent side effects increases. This is particularly relevant as over 50% of colorectal cancer patients in the UK currently survive more than 10 years (ONS 2019). There is a need for adjunctive therapies that can support colorectal cancer patients through conventional cancer therapy by alleviating symptoms and side effects without adversely affecting survival.

Coriolus versicolor is included in several resources aimed at cancer patients and health professionals (e.g. NCI 2022), and a number of reviews of the effects of mushrooms in cancer have been conducted previously. Within the Cochrane Database of Systematic Reviews, a review of *Ganoderma lucidum* (Reishi mushroom) for cancer treatment concluded that there was insufficient evidence to support its use as a first-line treatment for cancer or long-term cancer survival, but that it could be considered for use as an alternative adjunct to conventional treatment due to its potential to enhance tumour response and stimulate host immunity while being generally well-tolerated (Jin 2016). Several published systematic reviews have focused on *Coriolus versicolor* and its extracts. One meta-analysis published in 2012 focused on the effects of *Coriolus versicolor* on survival in cancer patients and concluded that there was strong evidence of a beneficial effect on survival, particularly in breast, gastric, and colorectal cancer patients (Eliza 2012). However, only research published up to 2003 was included. A second meta-analysis focused on the efficacy of PSK for survival of patients with curatively resected colorectal cancer; PSK used as an adjuvant to conventional chemotherapy improved overall and disease-free survival, but risk of bias and adverse events were not addressed (Sakamoto 2006). A review of safety data relating to medicinal mushrooms in cancer patients showed no evidence of cytotoxicity, mutagenicity, teratogenicity, effects on female ovulation, or reproduction at acute or chronic doses (Smith 2002). Adverse effects that have been reported include possible darkening of the fingernails and faeces (Kidd 2000). One review has assessed *Coriolus* efficacy and safety for a range of cancers (Zhong 2019), but no systematic review has been performed to evaluate the strength of evidence on the effects of *Coriolus versicolor* and its extracts on both adverse effects during cytotoxic treatment and on survival in colorectal cancer. Thus, a review focusing on evaluating the evidence on the adjuvant effects of *Coriolus versicolor* and its extracts in colorectal cancer was warranted.

OBJECTIVES

Primary objective

- To assess the effects of adjunctive *Coriolus versicolor* (*Trametes versicolor*) and its extracts on adverse effects during cancer treatment (chemotherapy and radiotherapy) compared with no adjunctive treatment.

Secondary objectives

- To assess effects due to adjunctive *Coriolus versicolor* (*Trametes versicolor*) and its extracts on survival, recurrence, and disease progression compared with no adjunctive treatment.
- To evaluate the evidence in relation to the type of preparation of the mushroom (e.g. whole fresh, dried, or extract).

METHODS

Criteria for considering studies for this review

Types of studies

We included randomised controlled trials (RCTs) investigating the efficacy and safety of *Coriolus versicolor* and its extracts in participants with a confirmed diagnosis of colorectal cancer, in addition to conventional treatment. We included trials regardless

of language and publication status. We considered all types of RCT design for inclusion, e.g. parallel-group and cluster-RCTs.

We only included trials in different types of cancer if data for colorectal cancer patients were reported separately.

Types of participants

Adult patients (minimum age 18 years) diagnosed with colorectal cancer regardless of tumour stage, age, or gender. Diagnosis must have been confirmed by biopsy and tumour site and stage reported. No limitations were set in terms of location, setting, or other demographic factors.

Types of interventions

Interventions included any preparation of *Coriolus versicolor* (raw plant, decoction, capsule, tablet, tincture, extract, injection), any part of the mushroom (cap, stem, mycelium or whole), in any dose and regimen.

Trials were included that compared:

- conventional treatment (chemotherapy with or without radiotherapy) plus *Coriolus versicolor* versus conventional treatment alone;
- conventional treatment and a complementary therapy plus *Coriolus versicolor* versus the same treatment without the extract;
- conventional treatment plus *Coriolus versicolor* versus conventional treatment plus placebo.

Types of outcome measures

We selected outcomes that directly measured effects on adverse events and those that may indicate indirect effects, such as withdrawal of treatment due to adverse events, which could ultimately affect survival and recurrence.

Primary outcomes

- Overall survival at one year, three years, and five years.
- Adverse event rates: the incidence of all reported adverse events or toxicities, including modification of treatment or withdrawal from the trial due to adverse events.

Secondary outcomes

- Disease progression at one year (plus three years and five years, if data were available) confirmed radiologically or proven by biopsy.
- Disease recurrence at one year (plus three years and five years, if data were available) confirmed radiologically or proven by biopsy.
- Response rates based on recommended criteria (World Health Organization (WHO) criteria or RECIST - Response Evaluation Criteria in Solid Tumors) for solid tumours (Therasse 2000).
- Quality of life evaluated using any validated assessment tool.

Search methods for identification of studies

We developed the MEDLINE search strategy and search strategies for databases other than MEDLINE in close collaboration with the Cochrane Colorectal Cancer Group Information specialist. For search strategies, see [Appendix 1](#)

We imposed no language restrictions and native speakers translated studies when required.

Electronic searches

We searched the following electronic databases.

- Cochrane Central Register of Controlled Trials (CENTRAL; 2022 Issue 4) in the Cochrane Library (searched 12 April 2022)
- MEDLINE Ovid (1946 to 12 April 2022)
- Embase Ovid (1974 to 12 April 2022)
- AMED Ovid (Allied and Complementary Medicine; 1985 to 12 April 2022)
- CINAHL EBSCO (Cumulative Index to Nursing and Allied Health Literature; 1982 to 12 April 2022)
- Natural Medicines database Therapeutic Research Center: <https://naturalmedicines.therapeuticresearch.com/databases/food,-herbs-supplements.aspx> (2022; searched 12 April 2022)
- Global Index Medicus (<http://www.globalindexmedicus.net/>) (searched 12 April 2022)
- BIOSIS Previews (inception to 2008)*

*Access to BIOSIS Previews only included records to 2008 as no further access could be obtained by the authors through their organisations but no unique studies were found on BIOSIS Previews and all included studies were indexed on databases other than BIOSIS Previews.

Trials registers

- ClinicalTrials.gov (<http://clinicaltrials.gov/>) (searched 12 April 2022)
- WHO International Clinical Trials Registry Platform (ICTRP) (<http://www.who.int/trialsearch>) (searched 12 April 2022)

Chinese databases

- Chinese Science and Technology Periodical Database (CQVIP) (www.cqvip.com)(1989-16 April 2022)
- Chinese National Knowledge Infrastructure Databases (CNKI) (www.cnki.net)(1979-16 April 2022)
- Wanfang Data's Chinese Online Journals database (<http://www.wanfangdata.com/>)(1985-16 April 2022)
- Chinese Biomedical Database web(CBM/Sinomed) (www.imicams.ac.cn).(1978-16 April 2022)

Japanese databases

- Ichushi Web (<http://www.jamas.or.jp>), web version of *Igaku Chuou Zasshi* (Japan centre revuo medicina) (from inception to 25 April 2022)

Searching other resources

We checked the reference lists of all retrieved studies and relevant reviews for further relevant studies. We handsearched the most recent year of the specialist International Journal of Medicinal Mushrooms to ensure that no relevant publications were missed that had not yet been indexed in the major databases (search carried out in May 2022). We attempted to contact authors and the manufacturer to check for unpublished trials (October 2020).

Data collection and analysis

Selection of studies

Two review authors independently examined all titles and abstracts retrieved by the searches of English databases (KP and LSW) and the Chinese and Japanese databases (JPL, XYJ and LT). If a record (title or abstract) could not be rejected with certainty, we obtained the full-text article for further evaluation. We excluded duplicate records but retrieved all publications pertaining to a relevant trial. Disagreements were resolved by discussion and a third review author was available had there been any disagreements. We documented the reasons for the exclusion of studies.

Data extraction and management

Two review authors (KP and LSW) independently extracted the following information: patients (number randomised and analysed, age, sex, stage, treatment situation, setting), methods (design, observation period, analysis), interventions (type of preparation, application, dose and duration, control procedure, cancer treatments), outcomes and results (reports of adverse events, survival data, data on quality of life (QoL), number of dropouts, follow-up). We used a pre-defined data extraction form for recording relevant data. Differences between review authors were resolved by discussion or, if necessary, by consulting a third review author. Cancer stage(s) and chemotherapy regimen in each study were also assessed by a clinical expert (DS).

In cases where numerical data were not presented in the study reports but there was information from figures or graphs, one review author (LSW) extracted estimates of numerical data from the figures using WebPlotDigitizer ([WebPlotDigitizer 2020](#)). The extracted data were visually compared to the figures by a second review author (KP).

For the trial that was only published in Chinese, two independent translations were obtained. Data were extracted from these by two review authors (KP and LSW) and the extracted data were then checked by a review author from China (XYJ). For studies where the primary publication was in English and supplementary publications were in English and Japanese, two review authors (KP and LSW) extracted data from the primary and any further publications in English and contacted the review author in Japan (LT) to check for any additional data provided by a Japanese publication.

Assessment of risk of bias in included studies

Two review authors (KP and LSW) independently assessed the trials using the Cochrane tool for assessing risk of bias ([Higgins 2011](#)). Differences were resolved by discussion or, if necessary, by consulting another review author. Assessment of risk of bias ([Appendix 2](#)) considers the following and we assessed this as per the criteria for judging risk of bias in the risk of bias assessment tool (Table 8.5.c) in the *Cochrane Handbook for Systematic Reviews of Interventions*.

- Sequence generation.
- Allocation concealment.
- Blinding of participants, personnel and outcomes assessors.
- Incomplete outcome data.
- Selective outcome reporting. This followed the methods as per the Cochrane risk of bias assessment mentioned above.

However, as a minimum we expected that trials should report adverse event data and survival or tumour response/disease progression.

- Other possible sources of bias: This includes potential biases that do not correspond to the above categories. They may include study-specific problems such as carryover in cross-over trials, more general problems in study conduct such as contamination between intervention arms, or that a study is claimed to be fraudulent.

Measures of treatment effect

We extracted the number of patients in each treatment arm who experienced the outcome of interest, in order to estimate a risk ratio (RR). If sufficient data were available, we categorised these according to the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) ([NCI 2017](#)). We planned to compare rates of adverse events at each grade of severity ([NCI 2017](#)). If data had been available, we planned to categorise adverse events as acute (during and up to six weeks after treatment) and late (after six weeks). Data for this were not available.

We present dichotomous data as RR with corresponding 95% confidence interval (CI). We present continuous data as a mean difference (MD) for common measurement units or a standardised mean difference (SMD) for differing measurement units and different scales, along with corresponding 95% CIs. We calculated effect size and 95% CI for all primary and secondary outcomes. Where possible, all data extracted are those relevant to an intention-to-treat analysis, in which participants are analysed in the groups to which they were assigned. We also noted the time points at which outcomes were collected and reported.

Unit of analysis issues

For individual trials, the unit of analysis is the individual patient. We had planned for the analysis of cluster-randomised study designs, but no trials using this design were identified. See [Appendix 3](#) for further details.

Dealing with missing data

We attempted to contact study authors for additional information on the studies. The contact author or senior author was contacted for all except one study where contact details could not be located. No responses were received. If contacting authors proved unsuccessful, we had planned to investigate the potential impact of the missing data (for further details, see [Appendix 3](#)). However, reporting of the trials was not sufficient to allow accurate assessment of the extent to which data were missing.

Assessment of heterogeneity

We assessed heterogeneity between studies by visual inspection of forest plots, by a formal statistical test of the significance of the heterogeneity (I^2) and, where possible, by subgroup analyses. Where heterogeneity was detected ($I^2 \geq 50\%$), we attempted to investigate possible reasons for this and consider whether it was appropriate to report a pooled estimate. Where there was evidence of substantial heterogeneity, we attempted to investigate and report the possible reasons.

Assessment of reporting biases

We had planned to examine funnel plots to assess the potential for small-study effects such as publication bias. We planned to check the symmetry of the funnel plot if a sufficient number of trials had been included in a meta-analysis (more than 10 trials). As only seven trials were located, we were unable to assess publication bias.

Data synthesis

Where sufficient clinically similar studies were available, we pooled their results in meta-analyses.

For any dichotomous outcomes, we calculated the RR for each study and then pooled these.

For continuous outcomes, we planned to pool the MDs between the treatment arms at the end of follow-up if all trials measured the outcome on the same scale, otherwise we planned to pool SMDs. As a continuous outcome was only reported by one trial, pooling was not possible.

We used random-effects models with inverse variance weighting for all primary analyses. We performed all analyses using the Cochrane statistical software, Review Manager 5.3 (RevMan 2014). One review author (LSW) oversaw all steps of data synthesis. We have summarised the results of included trials descriptively in tables.

Subgroup analysis and investigation of heterogeneity

We planned to perform subgroup analysis according to type of *Coriolus versicolor* preparation, dose, type of cancer (colon or rectal), stage of cancer and chemotherapy regimen. Two different commercial extracts have been used clinically in the Far East: polysaccharide-Krestin (PSK) and polysaccharopeptide (polysaccharide-peptide or PSP) (NCI 2022). We planned to compare the effects of these extracts and any other preparations of *Coriolus* that had been tested in relevant trials. The type of cancer, whether colon or rectal, has an influence on the treatment approach and the role of chemotherapy versus surgery (NICE 2020). There are also differences in recurrence rates (NICE 2020). Stage of cancer is also relevant for similar reasons. The chemotherapy regimen with which the *Coriolus* extract is given may affect outcomes as the nature and frequency of adverse effects vary according to the drugs involved.

Sensitivity analysis

We planned to perform sensitivity analysis excluding studies considered to be at high risk of bias.

Summary of findings and assessment of the certainty of the evidence

Two review authors (KP and LSW) independently evaluated the certainty of evidence for each estimate of effect using the Grading of Recommendations Assessment, Development and Evaluation

(GRADE) approach. Differences were resolved by discussion or, if necessary, by consulting another review author. The certainty of evidence for the primary outcomes of survival, and adverse events was presented in 'Summary of findings 1'. Among the survival outcomes we chose five-year survival as it was the longest prespecified survival point, and among adverse events we chose the adverse events that our clinical author (DS) identified as most concerning to patients, i.e. oral dryness and mucositis, nausea, diarrhoea, decreased neutrophils, and fatigue.

The GRADE system classifies the certainty of evidence in one of four grades.

1. High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.
2. Moderate certainty: we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.
3. Low certainty: our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect.
4. Very low certainty: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect.

The certainty of evidence can be downgraded by one (serious concern) or two levels (very serious concern) for the following reasons: risk of bias, inconsistency (unexplained heterogeneity, inconsistency of results), indirectness (indirect population, intervention, control, outcomes) and imprecision (wide confidence interval, single trial).

The certainty of evidence might be upgraded by one level due to a large summary effect.

We used GRADE Pro (see <https://gradepro.org/cite/>) to generate the summary of findings table.

RESULTS

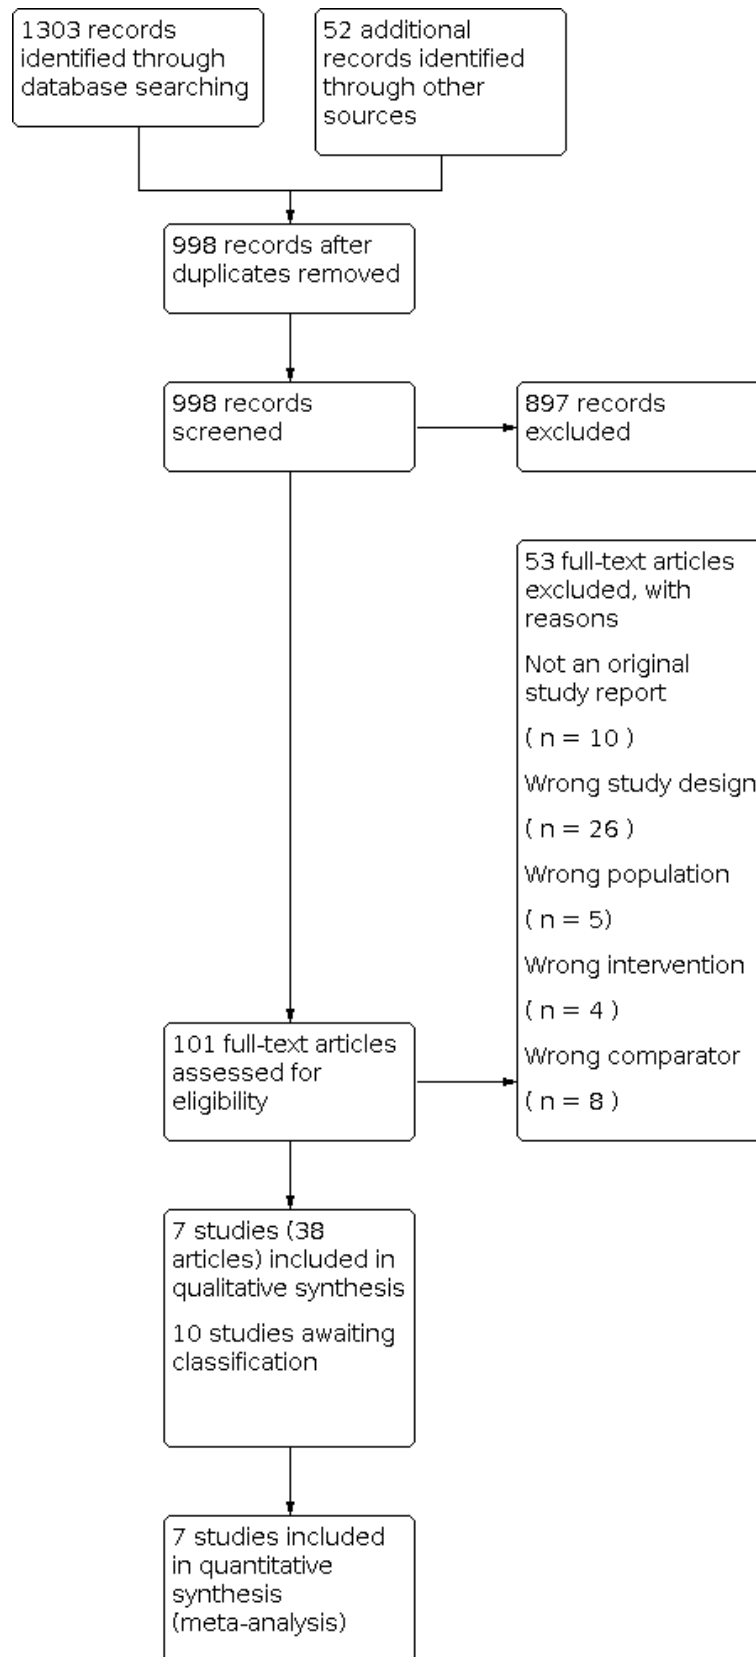

Description of studies

Results of the search

A total of 1355 records were retrieved across the databases and other sources. After deduplication, we screened titles and abstracts of 998 records and the full text of 101 records. Of the 53 records excluded at the full-text stage, 10 were not original study reports and the remaining 43 studies did not match the inclusion criteria (see [Excluded studies](#) for details).

We identified 48 records corresponding to 17 studies: seven studies (reported in 38 publications) met the inclusion criteria and were included in the review, and 10 studies (10 records) are awaiting classification. Several studies were associated with multiple reference records. In all cases, the study rather than the reference was the unit of interest in the review. The flow of studies is presented in the PRISMA chart in [Figure 1](#).

Figure 1. Study flow diagram.

Included studies

General characteristics

We included seven parallel RCTs (1569 participants). Six studies (1516 participants) were conducted in Japan (Ito 2004; Mitomi 1992; Ohwada 2004; Sadahiro 2010; Shichinohe 2013; Sugimoto 2012) and one study (53 participants) in China (Xu 2008). Six studies were published as full-text papers and one was only available as a conference abstract (Shichinohe 2013). Results from the six studies from Japan were published in both English and Japanese and the study from China was published in Chinese.

Participants

Six studies included both male and female participants (one study did not report gender). Mean age of participants was between 60 and 65 years in three studies (Ito 2004; Sadahiro 2010; Sugimoto 2012); median age was 61 in one study (Xu 2008); two studies reported age range only and included participants under 40 years and up to 75 years (Mitomi 1992; Ohwada 2004) and one study did not provide details of the age of participants (Shichinohe 2013). In five studies, participants included those with colon and/or rectal cancer; in one study only those with colon cancer (Ito 2004) and, in the remaining study, only those with rectal cancer (Sadahiro 2010). Various methods were used for staging cancer including Dukes, numerical and TNM systems. All studies included patients with stage II and/or III disease, and one study had patients with stage III and IV disease (Xu 2008). In five studies, the *Coriolus* extract was used after curative resection, in one study it was used preoperatively (Sadahiro 2010) and, in one study involving advanced cancer patients, it was unclear if surgery had been carried out (Xu 2008). A summary of the cancer type, stage and treatment is shown in Additional Table 1.

Setting

The setting for treatment was unclear in most studies but it appeared that most participants were treated as outpatients. Treatment given orally or via an intravenous dose on the first one or two postoperative days, once weekly or once a month.

Intervention and comparators

The intervention in all seven studies was described as polysaccharide-Krestin (PSK) used adjunctively; this was compared against no adjunctive treatment. PSK was administered orally at a dose of 3 g per day in all studies except one in which 6 g per day was given (Xu 2008). Treatment duration varied between four weeks and three years.

In one study, participants received PSK together with an oral fluoropyrimidine and radiotherapy prior to surgery (Sadahiro 2010). In the remaining six studies, PSK was used after surgery. In six

studies, PSK was used alongside chemotherapy. Chemotherapeutic regimens in five studies consisted of an oral fluoropyrimidine, which was preceded by weekly intravenous 5-fluorouracil (5-FU) in one study (Ito 2004), and by mitomycin C in two studies (Mitomi 1992; Ohwada 2004), and which was combined with folinic acid (Leucovorin) in two studies (Shichinohe 2013; Sugimoto 2012). The XELOX regimen (oxaliplatin intravenous infusion and capecitabine) was used in the remaining study (Xu 2008).

Outcomes measured

All studies assessed adverse events but, in two studies (Ohwada 2004; Shichinohe 2013), data were not provided by group. Five studies measured overall survival as a primary outcome while the two remaining studies focused on adverse effects and completion (Sugimoto 2012) and on immune responses and adverse effects (Shichinohe 2013). Four studies investigated the impact of adverse events on modification or withdrawal of treatment (Ito 2004; Mitomi 1992; Ohwada 2004; Sugimoto 2012). Five studies reported on disease-free survival and/or recurrence, but only one study assessed response and progression (Xu 2008). Quality of life was assessed in one study (Xu 2008). The outcomes measured by each study are presented in Table 2 and Table 3.

Funding sources

The source of funding was not reported in any study.

Excluded studies

Of the studies excluded at the full-text stage, 36 were not RCTs, eight studies did not use a comparator of interest, in five studies the sample recruited did not match the population of interest, and four studies did not use the intervention of interest.

Several apparently relevant studies involved comparisons that did not meet the inclusion criteria. In two cases, this was a comparison of surgery with a combination of tegafur/uracil (UFT) and PSK (Okuno 2017; Okuno 2018). One study compared PSK against leucovorin (Miyake 2018), while another study involved appropriate test and comparator interventions but allocated patients to groups according to their 'pathological characteristics and treatment demands' (Li 2019). Two studies compared PSK against placebo after curative resection until recurrence or metastases occurred, at which point chemotherapy was introduced (Torisu 1986; Torisu 1990).

Risk of bias in included studies

A summary of the risk of bias is shown in Figure 2 and the risk of bias judgements for individual studies are shown in Figure 3. The studies contributing to each pooled effect estimate are shown in Table 2 (non-adverse event outcomes) and Table 3 (adverse event outcomes).

Figure 2. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

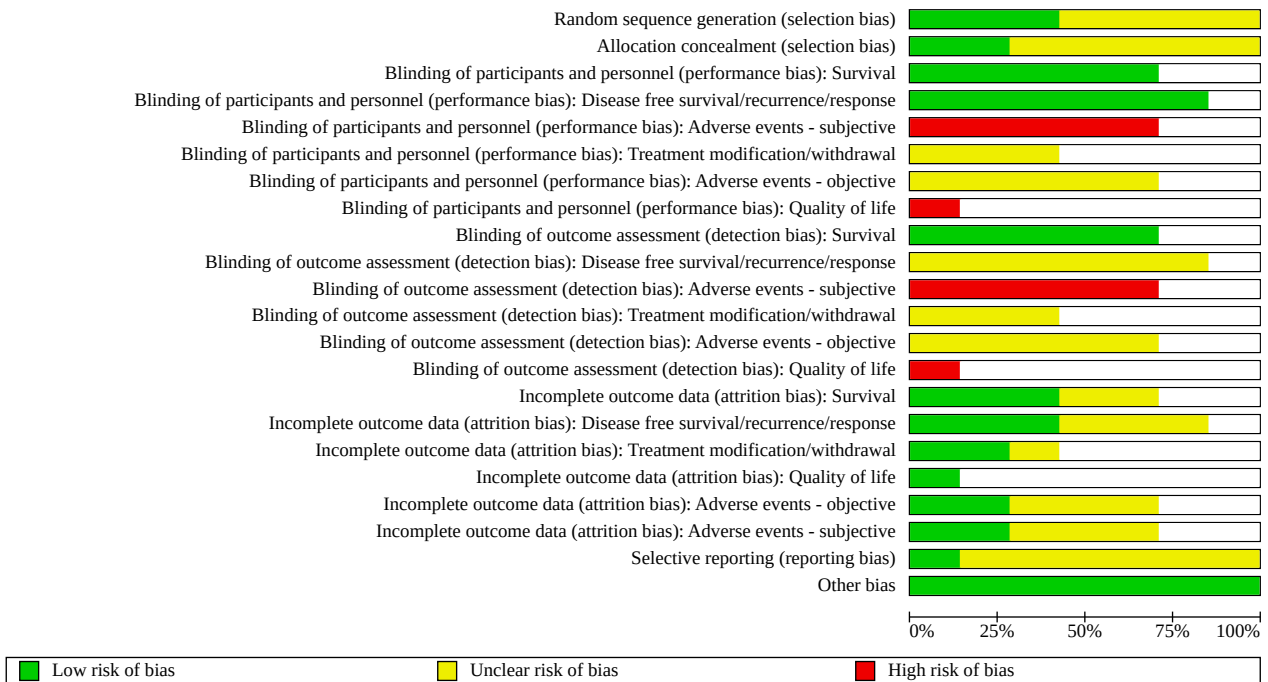

Figure 3. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.

Allocation

Three trials reported adequate randomisation methods or methods equivalent to randomisation including a modified minimisation method and permuted, stratified blocks and were judged to be at

low risk of bias. The remaining four trials, which included one trial reported only as an abstract (Shichinohe 2013), provided few or no details of randomisation and the risk of bias was assessed as unclear. Three of the trials were at low risk (Ito 2004; Mitomi 1992;

Ohwada 2004) and four trials were at unclear risk of bias (Sadahiro 2010; Shichinohe 2013; Sugimoto 2012; Xu 2008).

Two trials reported adequate allocation concealment through use of centralised allocation (Ito 2004; Ohwada 2004) with a low risk of bias. The remaining five trials (Mitomi 1992; Sadahiro 2010; Shichinohe 2013; Sugimoto 2012; Xu 2008) did not provide details of allocation concealment and so the risk of bias was assessed as unclear. Three of the trials contributing to meta-analyses on overall survival (Ito 2004; Mitomi 1992; Ohwada 2004) were low risk of bias and two (Shichinohe 2013; Xu 2008) were unclear risk of bias.

No studies were assessed as at high risk of bias in this domain.

Blinding

All seven studies involved adjuvant *Coriolus* extract with no placebo in the control group and so were not blinded.

Blinding of participants and/or personnel

Overall survival

We judged that lack of blinding of participants and/or personnel would not likely influence the occurrence of this outcome. The five trials (Ito 2004; Mitomi 1992; Ohwada 2004; Shichinohe 2013; Xu 2008) that assessed overall survival we judged to be at low risk of bias for this outcome.

Disease recurrence

We judged that lack of blinding of participants and/or personnel would not likely influence the occurrence of this outcome. The three trials (Mitomi 1992; Ohwada 2004; Sugimoto 2012) that assessed disease recurrence we judged to be at low risk of bias for this outcome.

Disease-free survival

We judged that lack of blinding of participants and/or personnel would not likely influence the occurrence of this outcome. The four trials (Ito 2004; Mitomi 1992; Ohwada 2004; Shichinohe 2013) that assessed disease-free survival we judged to be at low risk of bias for this outcome.

Disease response/progression (RECIST criteria)

We judged that lack of blinding of participants and/or personnel would not likely influence the occurrence of this outcome. The one trial (Xu 2008) that assessed disease response/progression we judged to be at low risk of bias for this outcome.

Modification/withdrawal of treatment due to adverse events

We judged that lack of blinding of participants and/or personnel had an unclear influence the occurrence of this outcome. The three trials (Ito 2004; Ohwada 2004; Sugimoto 2012) that assessed modification or withdrawal of treatment we judged to be at unclear risk of bias for this outcome.

Quality of life

We judged that lack of blinding of participants and/or personnel would lead to high risk of bias for this outcome. The one trial (Xu 2008) that assessed quality of life we assessed as at high risk of bias for this outcome.

Adverse events (objective)

We judged that lack of blinding of participants and/or personnel had an unclear influence on the occurrence of these outcomes. Five trials (Ito 2004; Mitomi 1992; Sadahiro 2010; Sugimoto 2012; Xu 2008) were judged to be at unclear risk of bias for these outcomes.

Adverse events (subjective)

We judged that lack of blinding of participants and personnel would lead to high risk of bias for these outcomes. Five trials (Ito 2004; Mitomi 1992; Sadahiro 2010; Sugimoto 2012; Xu 2008) were assessed to be at high risk of bias for these outcomes.

Blinding of outcome assessment

Overall survival

We judged that lack of blinding of participants and/or personnel would not likely influence the occurrence of this outcome. The five trials (Ito 2004; Mitomi 1992; Ohwada 2004; Shichinohe 2013; Xu 2008) that assessed overall survival we judged to be at low risk of bias for this outcome.

Disease recurrence

We judged that lack of blinding of outcome assessors had an unclear influence on this outcome. The three trials (Mitomi 1992; Ohwada 2004; Sugimoto 2012) that assessed disease recurrence we judged to be at unclear risk of bias for this outcome.

Disease-free survival

We judged that lack of blinding of outcome assessors had an unclear influence on this outcome. The four trials (Ito 2004; Mitomi 1992; Ohwada 2004; Shichinohe 2013) that assessed disease-free survival we judged to be at unclear risk of bias for this outcome.

Disease response/progression (RECIST criteria)

We judged that lack of blinding of outcome assessors had an unclear influence on this outcome. The one trial (Xu 2008) that assessed disease response/progression we judged to be at unclear risk of bias for this outcome.

Modification/withdrawal of treatment due to adverse events

We judged that lack of blinding of outcome assessors had an unclear influence the occurrence of this outcome. The three trials (Ito 2004; Ohwada 2004; Sugimoto 2012) that assessed modification or withdrawal of treatment we judged to be at unclear risk of bias for this outcome.

Quality of life

We judged that lack of blinding of outcomes assessors would lead to high risk of bias for this outcome. The one trial that assessed quality of life (Xu 2008) we assessed as at high risk of bias for this outcome.

Adverse events (objective)

We judged that lack of blinding of outcomes assessors had an unclear influence on the occurrence of these outcomes. Five trials (Ito 2004; Mitomi 1992; Sadahiro 2010; Sugimoto 2012; Xu 2008) were judged to be at unclear risk of bias for these outcomes.

Adverse events (subjective)

We judged that lack of blinding of outcome assessors would lead to high risk of bias for these outcomes. Five trials ([Ito 2004](#); [Mitomi 1992](#); [Sadahiro 2010](#); [Sugimoto 2012](#); [Xu 2008](#)) were assessed to be at high risk of bias.

Incomplete outcome data

Overall survival

We judged that the risk of attrition bias due to incomplete data was low for three trials ([Ito 2004](#); [Mitomi 1992](#); [Ohwada 2004](#)) and unclear for two trials ([Shichinohe 2013](#); [Xu 2008](#)) contributing data to the analysis for this outcome.

Disease recurrence

We judged that the risk of attrition bias due to incomplete data was low for two trials ([Ohwada 2004](#); [Sugimoto 2012](#)) and unclear for one trial ([Mitomi 1992](#)) contributing data to the analysis for this outcome.

Disease-free survival

We judged that the risk of attrition bias due to incomplete data was low for two trials ([Ito 2004](#); [Ohwada 2004](#)) and unclear for two trials ([Mitomi 1992](#); [Shichinohe 2013](#)) contributing data to the analysis for this outcome.

Disease response/progression (RECIST criteria)

We judged that the risk of attrition bias due to incomplete data was unclear for one trial ([Xu 2008](#)) contributing data to the analysis for this outcome.

Modification/withdrawal of treatment due to adverse events

We judged that the risk of attrition bias due to incomplete data was low for two trials ([Ohwada 2004](#); [Sugimoto 2012](#)) and unclear for one trial ([Ito 2004](#)) contributing data to the analysis for this outcome.

Quality of life

We judged that the risk of attrition bias due to incomplete data was low for one trial ([Xu 2008](#)) contributing data to the analysis for this outcome.

Adverse events (objective)

We judged that the risk of attrition bias due to incomplete data was low for two trials ([Sadahiro 2010](#); [Sugimoto 2012](#)) and unclear for three trials ([Ito 2004](#); [Mitomi 1992](#); [Xu 2008](#)) contributing data to the analysis for this outcome.

Adverse events (subjective)

We judged that the risk of attrition bias due to incomplete data was low for two trials ([Sadahiro 2010](#); [Sugimoto 2012](#)) and unclear for three trials ([Ito 2004](#); [Mitomi 1992](#); [Xu 2008](#)) contributing data to the analysis for this outcome.

Selective reporting

We did not identify any accessible or published protocol or registration for six trials. We judged these trials at unclear risk of reporting bias. For one trial, we identified a trial registration with which the reported outcomes corresponded ([Shichinohe 2013](#)). We judged this trial to be at low risk of reporting bias.

One trial contributing to meta-analyses on survival was judged low risk ([Shichinohe 2013](#)) and six trials ([Ito 2004](#); [Mitomi 1992](#); [Ohwada 2004](#); [Sadahiro 2010](#); [Sugimoto 2012](#); [Xu 2008](#)) were at unclear risk of bias.

Other potential sources of bias

We did not identify any more general problems in study conduct such as contamination between intervention arms, or suspicion of research fraud.

Effects of interventions

See: [Summary of findings 1 Adjunctive *Coriolus versicolor* compared to no adjunctive treatment for colorectal cancer treatment](#)

-See: [Summary of findings 1](#) for the main comparisons

We have provided a summary of the results for effects of interventions, shown in Data and analyses. Additional [Table 2](#) and [Table 3](#) show the studies that contributed to the pooled effect estimates for each outcome. The results of subgroup analyses comparing colon and rectal cancer are also included in Data and analyses.

Primary outcomes

Survival (Analysis 1.1). See [Figure 4](#)

Figure 4. Forest plot of comparison: 1 Adjuvant *Coriolus versicolor* vs no adjunctive treatment, outcome: 1.1 Survival.

Five studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on survival (Ito 2004; Mitomi 1992; Ohwada 2004; Shichinohe 2013; Xu 2008).

- At one year, there was very low-certainty evidence (downgraded for indirectness and imprecision) of little to no difference in survival (Analysis 1.1.1 risk ratio (RR) 1.02, 95% confidence interval (CI) 0.99 to 1.05; participants = 448; studies = 1).
- At three years, there was very low-certainty evidence (downgraded for risk of bias, inconsistency, indirectness and imprecision) of little or no difference in survival (Analysis 1.1.2 RR 1.04, 95% CI 0.94 to 1.15; participants = 958; studies = 4; I² = 59%). Heterogeneity at this time point may be due to differences in chemotherapy regimens in the studies contributing to this analysis.
- At five years, there was low-certainty evidence (downgraded for indirectness and imprecision) of a small improvement in survival with polysaccharide-Krestin (PSK), but not relevant to current therapy and, thus, unclear whether any advantage currently (Analysis 1.1.3 RR 1.08, 95% CI 1.01 to 1.15; participants = 1094; studies = 3; I² = 0%). number needed to treat for

an additional beneficial outcome (NNTB) 16 (95%CI 9 to 70). Absolute risk reduction 6% (95% CI 1% to 11%).

- At seven years, there was low-certainty evidence (downgraded for indirectness and imprecision) of little or no effect on survival (Analysis 1.1.4 RR 1.05, 95% CI 0.95 to 1.16; participants = 441; studies = 1).

Adverse events

Adverse events overall (Analysis 1.2)

Two studies assessed the total numbers of any adverse events due to adjunctive *Coriolus versicolor* versus no adjunctive treatment and of any serious adverse event (Sadahiro 2010; Sugimoto 2012).

- There was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of the effect on risk of any adverse event (Analysis 1.2.1 RR 1.27 95% CI 0.65 to 2.49; participants =80; studies = 2; I²=0%) and on the risk of any serious adverse event (Analysis 1.2.2 RR 0.95 95% CI 0.15 to

6.17; participants = 80; studies = 2; $I^2=0\%$). The 95% confidence intervals extend from reduced risk to a large increase in risk.

Blood and lymphatic system (Analysis 1.3)

Four studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of blood and lymphatic system-related adverse events (Ito 2004; Mitomi 1992; Sadahiro 2010; Xu 2008).

- There was low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of moderate benefit to no difference in risk of anaemia (Analysis 1.3.1 RR 0.78, 95% CI 0.57 to 1.07; participants = 972; studies = 4; $I^2 = 0\%$) and the effect on serious anaemia is uncertain (Analysis 1.3.2).

Cardiac system (Analysis 1.4)

One study assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of cardiac system-related adverse events (Mitomi 1992).

- There was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of the effect on the risk of palpitations (Analysis 1.4.1 RR 0.34, 95% CI 0.01 to 8.36; participants = 448; studies = 1). The 95% confidence interval extends from a large reduction to a large increase in risk.

Gastrointestinal system (Analysis 1.5). See Figure 5

Figure 5. Forest plot of comparison: 1 Adjuvant *Coriolus versicolor* vs no adjunctive treatment, outcome: 1.12 Adverse events (Gastrointestinal system).

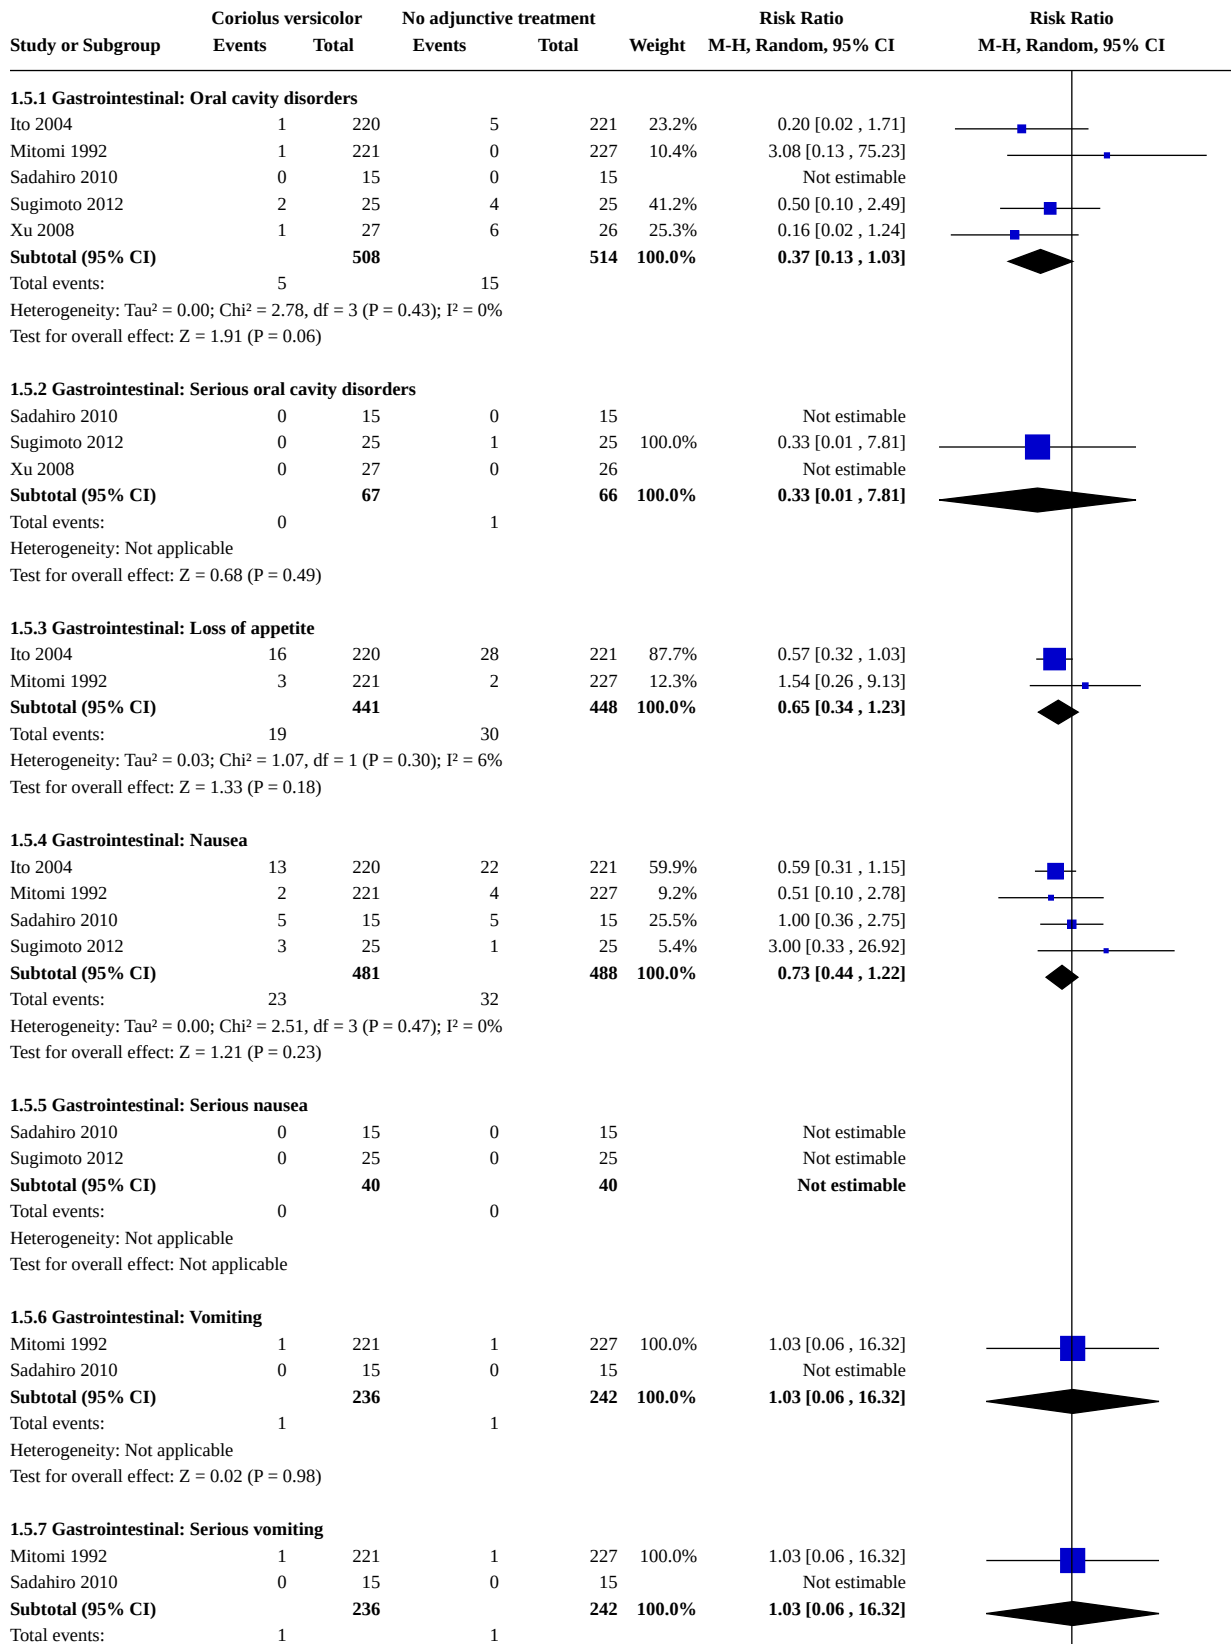

Figure 5. (Continued)

Five studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of gastrointestinal system-related adverse events (Ito 2004; Mitomi 1992; Sadahiro 2010; Sugimoto 2012; Xu 2008).

There was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision for each outcome) of the effect on the incidence of the following gastrointestinal system-related adverse events:

- oral cavity disorders (Analysis 1.5.1); loss of appetite (Analysis 1.5.3); nausea (Analysis 1.5.4); vomiting (Analysis 1.5.6); diarrhoea (Analysis 1.5.8); constipation (Analysis 1.5.10);

stomach discomfort (Analysis 1.5.11); gastric ulcer (Analysis 1.5.12);

- serious oral cavity disorders (Analysis 1.5.2); serious vomiting (Analysis 1.5.7); serious diarrhoea (Analysis 1.5.9);
- The estimates for the effect of adjunctive *Coriolus versicolor* varied across specific events, however, all effects are uncertain.

General disorders (Analysis 1.6)

Five studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of general adverse events (Ito 2004; Mitomi 1992; Sadahiro 2010; Sugimoto 2012; Xu 2008).

There was very low-certainty evidence (downgraded for risk of bias, indirectness (except for fatigue) and imprecision for each outcome) of the effect on the incidence of the following general adverse events:

- fatigue (Analysis 1.6.1 RR 0.76, 95% CI 0.33 to 1.78; participants = 133; studies = 3; $I^2 = 26\%$). The 95% confidence interval extends from a reduction to an increase in risk;
- pain (Analysis 1.6.3 RR 1.20, 95% CI 0.74 to 1.95; participants = 441; studies = 1). The 95% confidence interval extends from a reduction to an increase in risk;
- malaise (Analysis 1.6.4 RR 1.03, 95% CI 0.06 to 16.32; participants = 448; studies = 1). The 95% confidence interval extends from a large reduction to a large increase in risk.

Investigations (Analysis 1.7).

Five studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of investigation-related adverse events (Ito 2004; Mitomi 1992; Sadahiro 2010; Sugimoto 2012; Xu 2008).

There was very low-certainty evidence (downgraded for risk of bias, inconsistency, indirectness and imprecision for each outcome) of the effect on the incidence of the following adverse event:

- white blood cells (WBCs) decreased (Analysis 1.7.1 RR 0.88, 95% CI 0.44 to 1.74; participants = 972; studies = 4; $I^2 = 64\%$). Heterogeneity may be due to differences in chemotherapy regimens in the studies contributing to this analysis. The 95% confidence interval extends from a reduction to an increase in risk.

There was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of a reduction in the incidence of the following adverse events:

- neutrophils decreased (Analysis 1.7.3 RR 0.41, 95% CI 0.24 to 0.71; participants = 133; studies = 3; $I^2 = 0\%$) NNTB 5 (95% CI 3 to 15). Absolute risk reduction 21% (95% CI 7% to 36%);
- serious reduction in neutrophils (Analysis 1.7.4 RR 0.39, 95% CI 0.18 to 0.84; participants = 133; studies = 3; $I^2 = 0\%$). NNTB 8 (95% CI 4 to 64). Absolute risk reduction 14% (95% CI 2% to 26%).

There was very low-certainty evidence (downgraded for risk of bias, indirectness (except for : aspartate aminotransferase (AST)/alanine aminotransferase(ALT) and bilirubin increased) and imprecision for each outcome) of the effect on the incidence of the following adverse events:

- platelets decreased (Analysis 1.7.5) ; AST increased (Analysis 1.7.7) ; ALT increased (Analysis 1.7.8) ; AST/ALT increased (Analysis 1.7.9) ; ALP increased (Analysis 1.7.11) ; bilirubin increased (Analysis 1.7.12) ; creatinine increased (Analysis 1.7.14) ; abnormal hepatic function (Analysis 1.7.16).

Metabolism and nutrition disorders (Analysis 1.8)

One study assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of metabolism and nutrition disorders (Xu 2008).

- There was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision for each outcome) of the risk of low albumin levels (Analysis 1.8.1 RR 0.64, 95% CI 0.12 to 3.54; participants = 53; studies = 1). The 95% confidence interval extends from a large reduction to a large increase in risk.

Nervous system (Analysis 1.9)

Two studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of nervous system-related adverse events (Sugimoto 2012; Xu 2008).

There was very low-certainty evidence (downgraded for risk of bias, indirectness (neurotoxicity only) and imprecision for each outcome) of the effect on the incidence of nervous system-related adverse events:

- dysgeusia (Analysis 1.9.1 RR 2.00, 95% CI 0.19 to 20.67; participants = 50; studies = 1). The 95% confidence interval extends from a large reduction to a large increase in risk.
- neurotoxicity (Analysis 1.9.3 RR 0.74, 95% CI 0.40 to 1.38; participants = 53; studies = 1). The 95% confidence interval extends from a reduction to an increase in risk.

Skin and subcutaneous tissue disorders (Analysis 1.10)

Four studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on incidence of investigation-related adverse events (Ito 2004; Mitomi 1992; Sugimoto 2012; Xu 2008).

There was very low-certainty evidence (downgraded for risk of bias and imprecision for each outcome, and for indirectness for nail discolouration, skin hyperpigmentation, skin ulceration) of the effect on the incidence of the following skin-related adverse events:

- nail discolouration (Analysis 1.10.1); skin hyperpigmentation (Analysis 1.10.2) ; skin ulceration (Analysis 1.10.4) ; eruption (Analysis 1.10.8) ; skin disorders (not defined) (Analysis 1.10.9);
- serious skin hyperpigmentation (Analysis 1.10.3); serious skin ulceration (Analysis 1.10.5)

There was very low-certainty-evidence (downgraded for risk of bias, inconsistency, indirectness and imprecision for each outcome) of the effect on the incidence of the following skin-related adverse events:

- hand-foot syndrome (Analysis 1.10.6 RR 1.00, 95% CI 0.11 to 9.09; participants = 103; studies = 2; $I^2 = 58\%$). The 95% confidence interval extends from a large reduction to a large increase in risk. Heterogeneity may be due to differences in chemotherapy regimens in the studies contributing to this analysis.

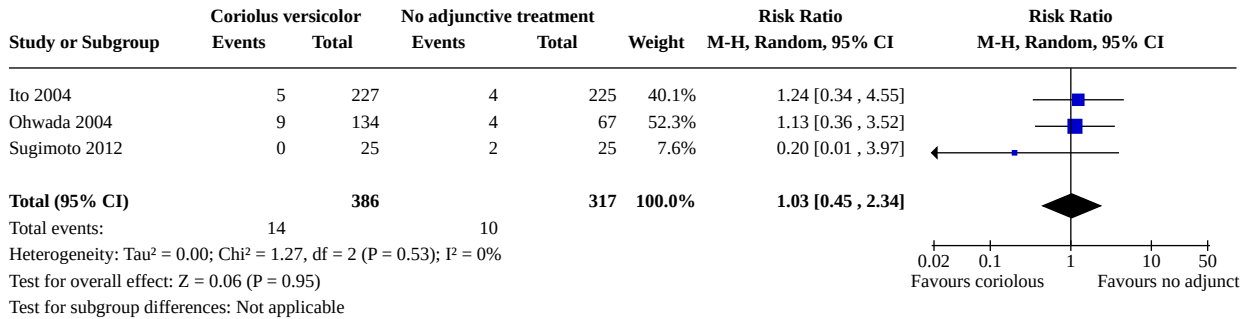

Modification of treatment due to adverse events (Analysis 1.11)

One study assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on modification of treatment due to adverse events (Sugimoto 2012).

- There was very low-certainty evidence (downgraded for risk of bias and imprecision) of the effect on modification of treatment due to adverse events (Analysis 1.11 RR 3.00, 95% CI 0.13 to 70.30; participants = 50; studies = 1). The 95% confidence interval extends from a large reduction to a large increase in risk.

Withdrawal from treatment due to adverse events (Analysis 1.12) See Figure 6

Figure 6. Forest plot of comparison: 1 Adjuvant *Coriolus versicolor* vs no adjunctive treatment, outcome: 1.7 Withdrawal from treatment due to adverse events.

Three studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on withdrawal from treatment due to adverse events (Ito 2004; Ohwada 2004; Sugimoto 2012).

- There was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of the effect on withdrawal from treatment due to adverse events (Analysis 1.12 RR 1.03, 95% CI 0.45 to 2.34; participants = 703; studies = 3; I² = 0%). The 95% confidence interval extends from a reduction to an increase in risk.

Secondary outcomes

Disease-free survival (Analysis 1.13)

Four studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on disease-free survival. Four studies contributed to the analyses (Ito 2004; Mitomi 1992; Ohwada 2004; Shichinohe 2013).

- At one year, there was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of little or no difference in effect on disease-free survival (Analysis 1.13.1 RR 1.05, 95% CI 0.99 to 1.13; participants = 448 studies = 1). The 95% confidence interval includes extends from a reduction to an increase in risk.
- At three years, there was very low certainty evidence (downgraded for risk of bias, inconsistency, indirectness and imprecision) of little or no difference in effect on disease-free survival (Analysis 1.13.2 RR 1.08, 95% CI 0.95 to 1.23; participants = 905; studies = 3; I² = 58%). The 95% confidence interval extends from a reduction to an increase in risk. Heterogeneity at this time point may be due to differences in chemotherapy regimens in the studies contributing to this analysis.
- At five years, there was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of no difference to a moderate benefit on disease-free survival (Analysis 1.13.3 RR 1.12, 95% CI 1.00 to 1.24; participants = 1091; studies = 3; I² = 41%).
- At seven years, there was low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of little or no difference in disease-free survival (Analysis 1.13.4 RR 1.04, 95% CI 0.93 to 1.17; participants = 441; studies = 1). The 95%

confidence interval extends from a reduction to an increase in risk.

Disease recurrence (Analysis 1.14)

Three studies assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on disease recurrence (Mitomi 1992; Ohwada 2004; Sugimoto 2012).

- At one year, there was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of the effect on disease recurrence (Analysis 1.14.1 RR 0.68, 95% CI 0.41 to 1.14; participants = 498; studies = 2; I² = 0%). The 95% confidence interval extends from a reduction to an increase in risk.
- At three years, there was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of a reduction in disease recurrence (Analysis 1.14.2 RR 0.70, 95% CI 0.52 to 0.96; participants = 448; studies = 1). NNTB 11, 95% confidence interval 6 to 76. Absolute risk reduction 10% (95% CI 1% to 18%).
- At five years, there was very low-certainty evidence (downgraded for risk of bias, indirectness and imprecision) of a reduction in disease recurrence (Analysis 1.14.3 RR 0.68, 95% CI 0.53 to 0.87; participants = 653; studies = 2; I² = NA). NNTB 9 (95% CI 6 to 24). Absolute risk reduction 11% (95% CI 4% to 18%).

Disease response/progression (RECIST criteria) (Analysis 1.15 and Analysis 1.16)

One study (53 participants) assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on response rates and progression (Xu 2008).

- There was very low-certainty evidence (downgraded for risk of bias and imprecision) of the effect on complete response (Analysis 1.15.1), partial response (Analysis 1.15.2), stable disease (Analysis 1.16.1) or in progressive disease (Analysis 1.16.2).

Quality of life (Analysis 1.17)

One study assessed the effects of adjunctive *Coriolus versicolor* versus no adjunctive treatment on quality of life (Xu 2008).

- There was very low-certainty evidence (downgraded for risk of bias and imprecision) of little to no effect on quality of life ([Analysis 1.17](#) MD -0.53, 95% CI -1.07 to 0.01; participants = 50; studies = 1). The 95% confidence interval includes a reduction and an increase in quality of life.

Subgroup analysis

We planned to perform subgroup analysis according to type of *Coriolus versicolor* preparation, dose, type of cancer (colon or rectal), stage of cancer and chemotherapy regimen. We found that all trials used one extract (PSK), and the dose used was consistent across studies so that no subgroup analysis was necessary. While all studies included patients with stage III cancer, most studies also included patients with either stage II or stage IV cancer and results were not reported separately by stage except in one study so that subgroup analysis was not carried out. All studies except one study used a regimen based on an oral fluoropyrimidine and so a formal subgroup analysis could not be carried out ([Deeks 2001](#)).

Three studies provided data for a subgroup analysis by type of cancer ([Ito 2004](#); [Mitomi 1992](#); [Ohwada 2004](#)). Visual inspection suggested that the effects on survival were similar at one year ([Analysis 2.1](#)) and three years ([Analysis 2.2](#)), but formal statistical testing could not be carried out as there was only one study in each subgroup at each time point ([Deeks 2001](#)). At five years, effects upon survival appeared similar for colon cancer ([Analysis 2.3](#) RR 1.06, 95% CI 0.99 to 1.14; participants = 690; studies = 2; $I^2 = 0\%$) and rectal cancer ([Analysis 2.3](#); RR 1.17, 95% CI 0.98 to 1.39; participants = 282; studies = 2; $I^2 = 0\%$), and this was consistent with the test for subgroup differences ($\text{Chi}^2 = 1.10$, $\text{df} = 1$ ($P = 0.29$), $I^2 = 9.3\%$). Visual inspection of data from one study ([Mitomi 1992](#)) suggested that the effects on disease recurrence appear slightly better for colon cancer than rectal cancer at all three time points ([Analysis 2.4](#); [Analysis 2.5](#); [Analysis 2.6](#)), however a formal subgroup test was not appropriate.

Sensitivity analysis

All studies were judged to be at high risk of bias for subjective outcomes (adverse events based on self-report and/or quality of life) but unclear or low risk for all other outcomes, therefore, sensitivity analysis for high risk of bias was not carried out.

DISCUSSION

Summary of main results

We found very low-certainty evidence of little to no difference in withdrawal from treatment due to adverse events resulting from adjunctive treatment with *Coriolus* (in the form of an extract, polysaccharide-Krestin (PSK)) (risk ratio (RR) 1.03, 95% confidence interval (CI) 0.45 to 2.34; 703 participants; 3 studies). We also found the effect on modification of treatment due to adverse events to be unclear with very low certainty evidence based on one small study. Evidence of an effect on the incidence of a range of specific adverse events was also of very low certainty. The events reported included haematological- and gastrointestinal-related adverse events amongst others. Thus, it is unclear if there was a difference in events including reduced white blood cell (WBC) counts, neutropenia, oral cavity disorders, nausea and diarrhoea.

We found low-certainty evidence of a small effect of adjunctive *Coriolus* extract on survival at five years compared with no

adjunctive extract (RR 1.08, 95% CI 1.01 to 1.15; 1094 participants; 3 studies; $I^2 = 0\%$). The effect at earlier time points was unclear with very low-certainty evidence (three-year survival: RR 1.04, 95% CI 0.94 to 1.15; 958 participants; 4 studies; $I^2 = 59\%$). Similar results were found for disease recurrence and disease-free survival with very low-certainty evidence at one, three and five years in both cases. Evidence on survival and on disease-free survival at seven years was low certainty but indicated that there may be little or no difference with the addition of the *Coriolus* extract.

Only one of the seven studies located used *Coriolus* extract in combination with a chemotherapy regimen currently preferred in practice (capecitabine and oxaliplatin) ([Xu 2008](#)). Chemotherapeutic regimens in six studies consisted of an oral fluoropyrimidine which was preceded by weekly intravenous 5-FU in one study and by mitomycin C in two studies, and which was combined with folinic acid (Leucovorin) in two studies while, in one study, it was combined with radiotherapy preoperatively. No evidence was found on products other than PSK or on populations outside China and Japan.

Overall completeness and applicability of evidence

Six of the studies that we found in this review were conducted in Japan and one study was carried out in China. We did not find studies that had been carried out in other countries or with other populations/ethnic groups. Participants represented both sexes, a range of ages and different stages of colorectal cancer although all studies included patients with stage III cancer. One study only included patients with rectal cancer, a second included only patients with colon cancer with the other studies including both. Only one form of *Coriolus* was investigated in the studies. This was PSK, an extract that was first developed as a proprietary product in Japan and which is no longer manufactured in Japan. No studies of other extracts or of the whole mushrooms were identified. While there was consistency in the dosage regimen for PSK, the duration of treatment varied from four weeks to three years. The studies had been carried out over a long period: only two of the seven studies were published in the past 10 years, the remaining five being reported more than 10 years ago. This is apparent from the varied treatment regimens used in each of the studies. In five studies, this involved oral 5-FU or UFT and one study utilised oral S-1. Several studies used regimens that are no longer in regular use and only one study used a regimen that is current preferred practice with the use of XELOX. Current practice was based on guidelines from China ([CSCO 2020](#)), Japan ([JSCCR 2019](#)), UK ([NICE 2020](#)) and US ([NCNN 2017](#); [NCNN 2018](#)).

Reporting of adverse events was very variable; several studies focused on whether PSK reduced adverse events while others focused on the extent to which it caused adverse events. We found reporting of methods for eliciting adverse events to be limited or unclear. We also found varied terminology used to describe adverse events. For consistency, we categorised adverse events according to Common Terminology Criteria for Adverse Events (CTAE) headings where possible. Timing of adverse events was not clear nor was causality. Lack of causality means that it was unclear if any adverse events were due to the chemotherapy or to the *Coriolus* extract. One study, which was excluded as it did not involve adjunctive *Coriolus*, specifically assessed frequency of adverse effects due to PSK compared with placebo and found a statistically significant difference in pigmentation of nails and cough on administration compared with placebo ([Torisu 1990](#)).

Other adverse effects of PSK have been reported but these are described as 'mild and tolerable' (Natural Database 2022). Several could be due to *Coriolus* or chemotherapy.

Quality of life, one of the secondary outcomes of interest in this review, was only assessed in one trial.

One study was published only as a conference abstract and another study as a short report so that details were limited. Several studies were reported in a series of publications and there was some inconsistency in reporting across publications. We were unable to obtain any further information on published data or any existing unpublished studies from study authors.

Quality of the evidence

We judged several studies to be at unclear risk of selection bias because randomisation was not clearly reported. None of the included studies blinded participants or providers to treatment assignment. Thus, there was a high risk of performance and detection bias for outcomes based on self-report such as adverse events that were subjective. Reporting bias was also unclear as registration and/or protocols were not available for six of the seven studies. For most outcomes, evidence was downgraded for risk of bias, indirectness and imprecision. Where several studies reported the same outcomes, we found little heterogeneity so that only a few of the comparisons required downgrading for inconsistency. Where significant heterogeneity ($I^2 < 50\%$) was observed, this could be explained by differences in the chemotherapy regimens in the studies contributing to the analysis, although this could not be confirmed by formal statistical testing. Different disease stages may involve different treatments (surgery, chemotherapy or radiotherapy) which in themselves affect adverse events either primarily and after PSK treatment. Due to the heterogeneity of patients and treatments reported in the publications, it was not possible to examine these aspects separately. Overall, none of the evidence was judged to be moderate or high certainty with most findings being very low certainty.

Potential biases in the review process

We carried out extensive searches of databases in Chinese, English and Japanese but were unable to obtain any further information on unpublished studies. This was due to many of the trials having taken place some time ago so that it was difficult to locate current contact details while the Japanese manufacturer discontinued the product used in most trials in 2017. It is possible that further unpublished data are available but, due to the small number of studies, it was not possible to examine publication bias using funnel plots. We did identify a number of clinical trials in trial registers for which we were unable to identify any publications (see [Studies awaiting classification](#)).

Several studies had been reported in a series of publications and we had to select the primary publication in each case. Where there was a discrepancy in reporting across publications, we had to make a decision on which data should be used.

We had at least two independent review authors select studies, extract data, and conduct risk of bias assessments. Where we extracted data based on translations, we consulted a review author who was fluent in the language for any points of clarification. There is, however, a slight possibility that certain aspects could be misconstrued during this process.

Agreements and disagreements with other studies or reviews

Four previous systematic reviews have addressed similar questions to our own. The first review focused on the efficacy of PSK used as an adjuvant to conventional chemotherapy in patients with curatively resected colorectal cancer (Sakamoto 2006). Similar results to those in this current review were found for PSK as an adjuvant on overall survival and disease-free survival at five years but risk of bias and adverse events were not addressed. Two further meta-analyses concluded that *Coriolus* had a beneficial effect on survival, including in colorectal cancer. In the first meta-analysis, only research up to 2003 was included (Eliza 2012), while we included an additional five studies published subsequently. The second was a network meta-analysis examining PSK for gastrointestinal cancer, including colorectal cancer (Ma 2017). Ma and colleagues also assessed effects on adverse effects. PSK was found to reduce the occurrence of nausea and vomiting, and leukopenia but, in contrast to the current review, the evidence was graded as moderate to high. The final review assessed *Coriolus* efficacy and safety for a range of cancers (Zhong 2019). Again, beneficial effects on survival were reported along with reductions in adverse effects, the most commonly encountered being similar to those in this review: nausea, vomiting, leucopenia, diarrhoea, thrombocytopenia, liver dysfunction, fatigue and anorexia. However, three of the four trials in colorectal cancer contributing to these conclusions were excluded in this current review. Overall, while there is some agreement on a possible small effect on overall survival, we rated the evidence as lower certainty. We also only found very low-certainty evidence on whether there was any reduction in adverse events including preventing withdrawal of treatment due to adverse events.

AUTHORS' CONCLUSIONS

Implications for practice

Due to the very low certainty of evidence, we are uncertain about the effect of *Coriolus* (in the form of an extract polysaccharide-Krestin (PSK)) on adverse events resulting from conventional chemotherapy for colorectal cancer. This was true for generic outcomes such as whether there was an effect on withdrawal of treatment due to adverse events and for specific adverse outcomes such as neutropenia and nausea. The uncertainty in the evidence also means that it was unclear whether any adverse events were due to the chemotherapy or to the extract itself. While there was low-certainty evidence of a small effect on overall survival at five years, the influence of reduced adverse effects on this could not be determined and evidence at other time points was unclear. Additionally, effect on survival was based on use of chemotherapy regimens which varied and included those that do not reflect current preferred practice. Thus, any benefits could not easily be translated into current practice.

Implications for research

We found a lack of research on the use of *Coriolus* extract in combination with currently prescribed chemotherapy regimens. Any future studies to assess whether there are beneficial effects, specifically in prevention or reduction of adverse events will need to systematically and comprehensively collect and collate data on all adverse events. Researchers would also need to record timing

of adverse events and carry out assessment of causality. Only PSK has been investigated in clinical trials and other products, such as Polysaccharide P, which are currently in use, require further assessment.

ACKNOWLEDGEMENTS

The review authors would like to acknowledge the valuable contribution of Dr. Janine Leach in first initiating this review, recruiting the team and to the development of the protocol. Dr Leach sadly passed away in June 2016.

The review authors are grateful for the advice of the NCRI Complementary Therapies Clinical Studies Development Group in the initial stages of this work, for the support of the Cochrane Colorectal Group and thanks to Marija Barbateskovic, Information Specialist, for the development of the search strategies.

Editorial and peer-reviewer contributions

The following people conducted the editorial process for this article.

Sign-off Editor (final editorial decision): Toby Lasserson, Cochrane Central Executive Team.

Managing Editor (selected peer reviewers, collated peer-reviewer comments, provided editorial guidance to authors, edited the article): Helen Wakeford, Cochrane Central Editorial Service.

Editorial Assistant (conducted editorial policy checks and supported editorial team): Leticia Rodrigues, Cochrane Central Executive Team.

Copy Editor (copy editing and production): Heather Maxwell.

Peer-reviewers (provided comments and recommended an editorial decision): Ping Chung Leung, Director of Centre for Clinical Trials on Chinese Medicine, Chinese University of Hong Kong (clinical/content review), Jeffrey D. White, Associate Director, Office of Cancer Complementary and Alternative Medicine, Division of Cancer Treatment and Diagnosis, National Cancer Institute, National Institutes of Health, US (clinical/content review), Nuala Livingstone, Cochrane Central Executive Team (methods review), Robin Featherstone, Cochrane Central Executive Team (search review). One additional peer reviewer provided clinical peer review, but chose not to be publicly acknowledged.

CHARACTERISTICS OF STUDIES
Characteristics of included studies [ordered by study ID]

Ito 2004
Study characteristics

Methods	Study design: parallel RCT
	Study location: Japan
	Study dates: enrolment February 1991 to March 1993
	Recruitment: patients recruited from 93 institutions in the Chubu region of Japan
	Number screened / eligible: not reported
	Inclusion criteria: quote: "primary colon cancer with curative resection and positive macroscopic lymph node metastases (macroscopic Dukes' C); under 75 years of age with PS 0 or 1; no serious complications; no preoperative treatment (radiation therapy, chemotherapy, immunotherapy) for can-

Coriolus (Trametes) versicolor mushroom to reduce adverse effects from chemotherapy or radiotherapy in people with colorectal cancer (Review)

34

Ito 2004 (Continued)

cer; no previous history of cancer; acceptable preoperative laboratory data (white blood cell count $\geq 3,000/\text{mm}^3$, platelet count $\geq 100,000/\text{mm}^3$, glutamic-oxaloacetic transaminase and glutamic-pyruvic transaminase ≤ 100 IU); preoperative records of serum carcinoembryonic antigen (CEA) level (below 5 ng/dl or not) and purified protein derivative (PPD) skin test reactions (smaller than 10 mm or not)"

Exclusion criteria: no additional criteria specified

Diagnostic criteria for inclusion/exclusion: quote: "primary colon cancer with curative resection and positive macroscopic lymph node metastases (macroscopic Dukes' C)"

Participants

Number randomised: 441; *Coriolus versicolor* (PSK) 220; control 221

Baseline imbalances: groups well-matched on most variables. Quote: "The clinical characteristics of the two study groups were similar at base line (Table 1). However, there was still an imbalance in the distribution of the patients' performance status (PS) between the two groups. Thus an adjusted analysis with two balancing factors (lymph node metastases, preoperative CEA level) and PS was adopted in the blinded review as a primary analysis."

Age: *Coriolus versicolor* (PSK) mean 60.4 years (87% age 50 or more); Control mean 60.0 (84% age 50 years or more). Overall mean = 60.0 years

Sex: *Coriolus versicolor* (PSK) male n = 123 (55.9%); Control male n = 121 (54.8%); Overall male n = 244 (55%)

Cancer type: colon

Cancer removed or present: removed

If cancer was present, was it local or metastatic: N/A. However note that there were positive lymph node metastases.

What was the aim of chemo/radiotherapy (if applicable)? adjuvant.

Withdrawals and exclusions: *Coriolus versicolor* (PSK) group withdrawals from treatment n = 25 (no hospital visits n = 11, adverse events n = 5, concomitant diseases n = 4, other n = 5); control group withdrawals from treatment n = 27 (no hospital visits n = 16, adverse events n = 4, concomitant diseases n = 2, others n = 5).

Interventions

***Coriolus versicolor* intervention:** oral protein-bound polysaccharide K (PSK) . Dose of 3 g/day from 29 days post-op for 4 weeks, followed by start of oral 5-FU for 4 weeks. Ten pairs of PSK followed by 5-FU treatments = 80 weeks of alternating treatment beginning at four weeks post-op.

Control intervention: chemotherapy alone

Chemotherapy regimen: 5-FU IV 1,000 mg/m²/24hr on postoperative days 1-2, 8, 9, 15, 16, 22 and 23, followed by 4 weeks PSK 3 g/day alternating with 4 weeks 5-FU oral 200 mg/day for a total of 10 cycles.

Planned length of treatment: 80 weeks.

Setting: not described but presumably hospital outpatient.

Co-interventions: none mentioned.

Outcomes

1. Survival
2. Disease-free survival
3. Treatment modification/withdrawal
4. Adverse events

Planned length of follow-up from treatment initiation: 7 years

Time points: Survival and disease-free survival reported at 5 and 7 year follow-up.

Ito 2004 (Continued)

Other outcomes: cancer-related deaths, survival from cancer-related death, and laboratory tests, including white blood cell, neutrophil, etc., oxidative stress index using the ROMs Test to measure hydroperoxide concentration, and salivary chromogranin A.

Adverse event assessment: no description of how adverse events were assessed. All adverse events are reported according to numbers of each event and to numbers of patients/year experiencing each event, not to numbers of people experiencing each adverse event as of Year 7 or any other time point.

Notes

Study name: Study Group of Immunochemotherapy with PSK for Colon Cancer

Funding source: no description of funding.

Declaration of interest: none declared.

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Quote: "Patients were allocated to either the PSK group (group P, n=220) or control group (group C, n=221) according to a dynamic balancing method (modified minimization method) using three balancing factors and institution"
Allocation concealment (selection bias)	Low risk	Quote: "based on central-registration method between 25 and 28 postoperative days. The randomized results processed in a computed system with the intention of concealment and adequate randomization"
Blinding of participants and personnel (performance bias) Survival	Low risk	No blinding however no likely influence of unblinding upon survival.
Blinding of participants and personnel (performance bias) Disease free survival/recurrence/response	Low risk	No blinding however no likely effect upon disease progression or recurrence.
Blinding of participants and personnel (performance bias) Adverse events - subjective	High risk	No blinding and may have affected experience of adverse events.
Blinding of participants and personnel (performance bias) Treatment modification/withdrawal	Unclear risk	No blinding and may have affected treatment decisions.
Blinding of participants and personnel (performance bias) Adverse events - objective	Unclear risk	No blinding and effect upon adverse events unclear.
Blinding of outcome assessment (detection bias) Survival	Low risk	No blinding of outcome assessors reported however low risk of bias in ascertainment of death.
Blinding of outcome assessment (detection bias)	Unclear risk	No blinding described and unclear how assessment carried out.

Ito 2004 (Continued)

 Disease free survival/re-
 currence/response

Blinding of outcome assessment (detection bias) Adverse events - subjective	High risk	No blinding described and high risk that assessment may have been affected.
Blinding of outcome assessment (detection bias) Treatment modification/withdrawal	Unclear risk	No blinding described and unclear how assessment carried out.
Blinding of outcome assessment (detection bias) Adverse events - objective	Unclear risk	No blinding described and unclear how assessment carried out.
Incomplete outcome data (attrition bias) Survival	Low risk	Appears complete outcome assessment and reporting.
Incomplete outcome data (attrition bias) Disease free survival/re- currence/response	Low risk	Appears complete outcome assessment and reporting.
Incomplete outcome data (attrition bias) Treatment modification/withdrawal	Unclear risk	Appears complete outcome assessment and reporting.
Incomplete outcome data (attrition bias) Adverse events - objective	Unclear risk	Unclear whether complete assessment was conducted and reported.
Incomplete outcome data (attrition bias) Adverse events - subjective	Unclear risk	Unclear whether complete assessment was conducted and reported.
Selective reporting (reporting bias)	Unclear risk	Protocol is mentioned but a registration or publication was not accessible.
Other bias	Low risk	No potential biases were apparent that do not correspond to the above categories (including study-specific problems such as carryover in cross-over trials, more general problems in study conduct such as contamination between intervention arms, or that a study is claimed to be fraudulent).

Recruitment: patients recruited by attending physicians at 25 institutions in Kanagawa Prefecture.

Number screened / eligible: 462/448

Inclusion criteria: primary cancer of the colon and rectum, any TN1, 2, 3MO or T4NOMO; macroscopically curative resection, under 75 years old, informed consent

Exclusion criteria: had received cancer therapy before resection, multiple or duplicated carcinoma, severe complications, or abnormal laboratory values (WBC, PLT, protein, albumin, A/G, SGOT-SGPT, urine protein or creatinine)

Diagnostic criteria for inclusion/exclusion: primary cancer of the colon and rectum, any TN1, 2, 3MO or T4NOMO

Participants

Number randomised: 448; 227 control; 221 intervention

Baseline imbalances: groups well-matched on most variables except for rectal tumour size (larger in PSK group).

Age: PSK: under 40 n = 14; 40-49 n = 37; 50-59 n=67; 60-69 n = 71; 70+ n=32. Control: under 40 n = 13; 40-49 n = 41; 50-59 n = 74; 60-69 n = 63; 70+ n = 36. Overall (calculated): under 40 n = 27; 40-49 n = 78; 50-59 n = 141; 60-69 n = 134; 70+ n = 68.

Sex: *Coriolus versicolor* (PSK): 125 men/96 women; Control: 128 men/99 women; Overall: 253 men/195 women

Cancer type: colorectal. PSK group colon = 124 rectum = 97; Control group colon = 125 rectum n = 102; Overall colon = 249 rectum = 199

Cancer removed or present: removed

If cancer was present, was it local or metastatic?: N/A

What was the aim of chemo/radiotherapy (if applicable)? adjuvant

Withdrawals and exclusions: PSK group withdrawals from chemotherapy treatment n = 30 (reasons described as similar to those in control group) and withdrawals from PSK treatment n=26 (report states that few side effects were caused by PSK); control group withdrawals from treatment n =27 (side effects n = 13; postoperative complications n = 9; reasons not reported n = 5)

Interventions

***Coriolus versicolor* intervention:** oral protein-bound polysaccharide K (PSK) manufactured by Kureha Chemical Industry Co. Ltd., 3 g/day, quote: "for over three years" plus chemotherapy as below

Control intervention: chemotherapy alone

Chemotherapy regimen: Mitomycin C (6.0 mg/m²) IV on day of and day after surgery, followed by oral 5-FU (200 mg per day) administration quote: "for more than 6 months"

Planned length of treatment: at least 6 months or until recurrence for chemotherapy and 3 years for PSK

Setting: not described but presumably hospital outpatient

Co-interventions: none mentioned

Outcomes

1. Survival
2. Disease free-survival
3. Disease recurrence
4. Treatment modification/withdrawal
5. Adverse events

Mitomi 1992 (Continued)

Planned length of follow-up from treatment initiation: plans unclear; follow-up data to 5 years

Time points: survival and recurrence reported at 1-, 2-, and 3-year follow-up.

Adverse event assessment: no description of how adverse events were assessed. While the specific side effects for which treatment was abbreviated are reported and there is a total number of these in each group, there is no information on the timing or number of people experiencing side effects.

Adverse events - subjective

Blinding of outcome assessment (detection bias) Adverse events - objective	Unclear risk	No blinding and possible risk of bias in assessment.
Incomplete outcome data (attrition bias) Survival	Low risk	Appears complete assessment and reporting.
Incomplete outcome data (attrition bias) Disease free survival/recurrence/response	Unclear risk	Unclear whether all data captured and reported.
Incomplete outcome data (attrition bias) Adverse events - objective	Unclear risk	Unclear whether complete assessment was conducted and reported.
Incomplete outcome data (attrition bias) Adverse events - subjective	Unclear risk	Unclear whether complete assessment was conducted and reported.
Selective reporting (reporting bias)	Unclear risk	No protocol or registration available.
Other bias	Low risk	No potential biases were apparent that do not correspond to the above categories (including study-specific problems such as carryover in cross-over trials, more general problems in study conduct such as contamination between intervention arms, or that a study is claimed to be fraudulent).

Ohwada 2004
Study characteristics

Methods	<p>Study design: parallel RCT</p> <p>Study location: Japan</p> <p>Study dates: enrolment October 1994 to March 1997</p> <p>Recruitment: patients recruited at 19 affiliate hospitals of the Second Department of Surgery, Gunma University Hospital, Maebashi, Japan</p> <p>Number screened / eligible: not reported</p> <p>Inclusion criteria: age < 75 years, histologically-confirmed colorectal cancer, stage II or III primary tumour, measurable IAP levels</p> <p>Exclusion criteria: previous radiotherapy, chemotherapy, or immunotherapy, or had multiple cancers, or severe complications. Also, abnormal white blood cell or platelet count; total protein, serum alanine or aspartate aminotransferase level or creatinine level.</p> <p>Diagnostic criteria for inclusion/exclusion: histological confirmation, stage II or III</p>
Participants	<p>Number randomised: 205; <i>Coriolus versicolor</i> (PSK) 139 (137 analysed); control 68</p>

Ohwada 2004 (Continued)

Baseline imbalances: groups well-matched on most variables. Quote: "There were no striking differences between the groups with respect to stratification factors or the histopathologic characteristics, including pathologic staging, pathologic regional lymph nodes, lymphatic invasion, venous invasion, and residual tumour excluding histopathologic grade. The histopathologic grade was higher in the PSK group than in the control group (P = 0.009)."

Age: *Coriolus versicolor* (PSK) age 25 to 49 n = 14 (10.5%), 50 to 59 n = 33 (24.1%), 60 to 69 n = 57 (41.6%), 70 to 75 n = 33 (24.1%). Control: age 25 to 49 n = 8 (11.9%), 50 to 59 n = 17 (25.0%), 60 to 69 n = 31 (45.6%), 70 to 75 n = 12 (17.9%). Overall: age 25 to 49 n = 22 (10.7%), 50 to 59 n = 50 (24.4%), 60 to 69 n = 88 (49.2%), 70 to 75 n = 45 (22%)

Sex: *Coriolus versicolor* (PSK) male n = 71, female n = 66; Control male n = 43, female n = 25; Overall male n = 114, female n = 91

Cancer type: colorectal. *Coriolus versicolor* (PSK) colon n = 88 (64.2%) rectum n = 49 (35.8%); Control colon n = 34 (50%) rectum n = 34 (50%); overall colon n = 122 rectum n = 83

Cancer removed or present: removed

If cancer was present, was it local or metastatic?: N/A

What was the aim of chemo/radiotherapy (if applicable)? adjuvant

Withdrawals and exclusions: *Coriolus versicolor* (PSK) = 6 (4 refusals and 2 ineligible); Control = 1 refusal

Interventions

***Coriolus versicolor* intervention:** quote: "oral PSK (3.0 g day⁻¹) and UFT (300 mg day⁻¹), starting 2 weeks after surgery and continuing for 2 years or until the diagnosis of tumour recurrence." plus chemotherapy as below

Control intervention: chemotherapy alone

Chemotherapy regimen: quote: "All registered patients received bolus injections of 12 and 8mgm-2 MMC (Kyowa Hakko, Inc., Japan) on postoperative days 1 and 2, respectively. All patients received UFT (300 mg day⁻¹), starting 2 weeks after surgery and continuing for 2 years or until the diagnosis of tumour recurrence."

Planned length of treatment: 2 years

Setting: not described but presumably hospital outpatient

Co-interventions: none mentioned

Outcomes

1. Survival
2. Disease-free survival
3. Disease recurrence
4. Treatment modification/withdrawal
5. Adverse events

Planned length of follow-up from treatment initiation: 5 years

Time points: survival and disease-free survival reported at 3 and 5-year follow-up, recurrences reported at 5 years.

Other outcomes: specific sites of recurrence.

Adverse event assessment: follow-up investigations (every 2 weeks for first month after discharge, then monthly for two years and then every 2-3 months until 3 years after surgery) included interview about drug toxicities which were recorded according to WHO criteria.

Other bias	Low risk	No potential biases were apparent that do not correspond to the above categories (including study-specific problems such as carryover in cross-over trials, more general problems in study conduct such as contamination between intervention arms, or that a study is claimed to be fraudulent).

Shichinohe 2013
Study characteristics

Methods

Study design: parallel RCT

Study location: Japan

Study dates: not reported

Recruitment: recruited from 35 different facilities but no detail about procedures

Number screened/eligible: not clear. 342 patients "registered"

Inclusion criteria: patients aged 20-80 years with primary colonic carcinoma or rectal carcinoma of histological stage III, who have undergone histological curability A or B surgeries; patients evaluated histologically as lymph node metastasis positive; performance status 0 to 2; no receipt of preoperative cancer therapy (radiotherapy, chemotherapy or immunotherapy); no diarrhoea (watery stool); no severe impairment of renal, hepatic and bone marrow functions; no serious concurrent complications (such as infection). (Data from trial registration NCT00209742)

Exclusion criteria: patients graded as curability C; with stenosis not capable of oral intake; if disease stage IIIa those that are si/n(-) and ai/n(-); fresh haemorrhage from the gastrointestinal tract; retention of body fluid necessitating treatment; infection, intestinal palsy or intestinal occlusion; lower end of the tumour involving the peritoneal reflection; lower rectal cancer (Rb), involving the anal canal (P) or perianal skin (E); active multiple cancers; or even if the multiple cancers are metachronous, have a disease-free period of less than 5 years (but excluding cancer in situ and skin cancer); pregnant or hope to become pregnant during the study period; poorly controlled diabetes or are treated by continuous use of insulin; a history of ischaemic heart disease; concurrent psychiatric disease or psychotic symptoms, and judged to have difficulties participating in the study; receiving continuous administration of steroids; serious drug allergy in the past. (Data from trial registration NCT00209742)

Diagnostic criteria for inclusion/exclusion: quote: "histological stage III and curability A or B colorectal cancer [according to General Rules for Clinical and Pathological Studies on Cancer of the Colon, Rectum and Anus, 6th edition (Japanese Classification of Colorectal Cancer, English edition), also according to pTNM classification to facilitate overseas publication]" (Data from trial registration NCT00209742)

Shichinohe 2013 (Continued)

Participants	<p>Number randomised: 340 "analyzed" presumably this also refers to number randomised however this is not explicit in the meeting abstract; <i>Coriolus versicolor</i> (PSK) with UFT+LV for 6 months and UFT for 12 months n = 171; UFT+LV for 6 months and UFT for 12 months n = 85; UFT+LV for 6 months n = 84.</p> <p>Baseline imbalances: quote: "At baseline, variation in QOL score was observed but histopathological parameters were not different among 3 groups."</p> <p>Age: NR</p> <p>Sex: NR</p> <p>Cancer type: colorectal (no further details)</p> <p>Cancer removed or present: removed</p> <p>If cancer was present, was it local or metastatic? : N/A. However, note that based on trial registration lymph node metastasis positive was an eligibility criterion.</p> <p>What was the aim of chemo/radiotherapy (if applicable)? adjuvant</p> <p>Withdrawals and exclusions: No mention of withdrawals or exclusions.</p>
Interventions	<p>Coriolus versicolor intervention: oral protein-bound polysaccharide K (PSK). Dose not reported. Given with UFT+LV "28 days/5 weeks for 6 months" then with UFT for 12 months plus chemotherapy as below</p> <p>Control intervention: chemotherapy as below</p> <p>Chemotherapy regimen: the chemotherapy regimen carried out with and without PSK was "UFT+LV 28 days/5 weeks for 6 months, then UFT for 12 months". A third group was given "UFT/LV 28 days/5 weeks for 6 months" and no UFT afterwards.</p> <p>Planned length of treatment: 18 months</p> <p>Setting: not described but presumably hospital outpatient</p> <p>Co-interventions: none mentioned</p>
Outcomes	<ol style="list-style-type: none"> 1. Survival 2. Disease-free survival 3. Quality of life (instrument not mentioned, percentage with "high score" reported) 4. Adverse events <p>Planned length of follow-up from treatment initiation: 5 years</p> <p>Time points: trial registration mentions outcomes to 5 and 7 years but abstract mentions only 3-year outcomes.</p> <p>Other outcomes: compliance and adverse events</p> <p>Adverse event assessment: methods of assessment and numbers of events or persons not mentioned, however adverse events were assessed and discussed: quote: "Adverse events \geq grade 3 included gastrointestinal symptoms and general status. There was no treatment-related death."</p>
Notes	<p>Study name: Hokkaido Gastrointestinal Cancer Study Group</p> <p>Funding source: no description of funding</p> <p>Declaration of interest: none declared</p>

Risk of bias

Baseline imbalances: none quote: "With respect to the patient backgrounds, i.e. gender, age, UFT administration dose, location and other clinicopathological factors, there were no significant differences between the PSK (–) group and the PSK (+) group (Table—1, 2."

Age: *Coriolus versicolor* (PSK) group mean (SD) 63.8 (10.9) years; non-PSK group mean (SD) 63.1 (8.4) years; Total not calculated.

Sex: *Coriolus versicolor* (PSK) group male/female 13/12; non-PSK group male/female 17/8; Total male/female 30/20

Cancer type: colorectal. PSK group colon n = 16/25 (64%) rectum n = 9/25 (36%); non-PSK group colon n = 14/25 (56%) rectum n = 11/25 (44%); Total colon n = 30/50 (60%) rectum n = 20/50 (40%)

Cancer removed or present: curative resection

If cancer was present, was it local or metastatic: N/A. However note possible metastatic cancer post resection, as Stage II colorectal cancers with lymphatic/venous invasion were defined as high-risk Stage II and eligible for inclusion.

What was the aim of chemo/radiotherapy (if applicable)? adjuvant

Withdrawals and exclusions: PSK group 1 dose reduction due to adverse events, 1 discontinuation due to recurrence; non-PSK group colon 2 discontinuations due to adverse events, 1 discontinuation due to recurrence

Interventions

***Coriolus versicolor* intervention:** oral protein-bound polysaccharide K (PSK) (KRESTIN®), 3 g/day, every day. The PSK was started when the UFT/LV was started.

Control intervention: chemotherapy alone

Chemotherapy regimen: oral UFT/LV (UFT® ; tegafur/uracil, Taiho Pharmaceuticals Co., Japan, LV ; calcium leucovorin, Wako Pure Chemical Industries, Japan) dose was UFT 300mg/m²/day and LV 7.5mg/day. Dosing was started 4-8 weeks after surgery and continued for 6 months or until the diagnosis of tumour recurrence. The UFT/LV was administered for 5 consecutive days, followed by 2 days in which the drug was not administered (5 days-on/2 days-off schedule.)

Planned length of treatment: 6 months or until tumour recurrence

Setting: not described but presumably hospital outpatient

Co-interventions: none mentioned

Outcomes

1. Disease recurrence
2. Treatment modification/withdrawal
3. Adverse events

Planned length of follow-up from treatment initiation: 6 months or until diagnosis of tumour recurrence

Sugimoto 2012 (Continued)

Time points: survival and recurrence reported at 6 months, laboratory values assessed and reported at baseline and 1, 3, and 6 month follow-up.

Other outcomes: laboratory tests (NK cells, white blood cells, neutrophils, red blood cells, platelets, AST, ALT, total bilirubin, creatine, reactive oxygen metabolites, salivary chromogranin A)

Adverse event assessment: quote: "Assessment of adverse events was performed using the Common Terminology Criteria for Adverse Events ver. 4.0 (CTCAE ver. 4.0)" (Accessed June 12, 2011, via the NIH Cancer Therapy Evaluation Program (CTEP) at <http://ctep.cancer.gov>). The authors do not specify how this was assessed in the patients. The authors do not specify how they categorised adverse events as serious/not serious, however based on the description at <https://www.biooncology.com/clinical-trials/safety-endpoints.html> it would appear that Grade 3 or higher would qualify as serious.

Notes

Study name: none

Funding source: no description of funding

Declaration of interest: States that authors have no conflict of interest

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Method of generating random sequence is not specified.
Allocation concealment (selection bias)	Unclear risk	Not reported
Blinding of participants and personnel (performance bias) Disease free survival/recurrence/response	Low risk	No blinding however no likely effect upon disease progression or recurrence
Blinding of participants and personnel (performance bias) Adverse events - subjective	High risk	No blinding and effect upon experience of adverse events is at high risk of bias
Blinding of participants and personnel (performance bias) Treatment modification/withdrawal	Unclear risk	No blinding and effect upon treatment decisions unclear
Blinding of participants and personnel (performance bias) Adverse events - objective	Unclear risk	No blinding and effect upon adverse events unclear
Blinding of outcome assessment (detection bias) Disease free survival/recurrence/response	Unclear risk	No blinding and unclear how assessment carried out.
Blinding of outcome assessment (detection bias)	High risk	No blinding and subjective assessment of outcomes at high risk of bias.

Sugimoto 2012 (Continued)

Adverse events - subjective

Blinding of outcome assessment (detection bias) Treatment modification/withdrawal	Unclear risk	No blinding and unclear how assessment carried out.
Blinding of outcome assessment (detection bias) Adverse events - objective	Unclear risk	No blinding and unclear how assessment carried out.
Incomplete outcome data (attrition bias) Disease free survival/recurrence/response	Low risk	Assessment and reporting of outcome appears complete.
Incomplete outcome data (attrition bias) Treatment modification/withdrawal	Low risk	Assessment and reporting of outcome appears complete.
Incomplete outcome data (attrition bias) Adverse events - objective	Low risk	Assessment and reporting of outcome appears complete.
Incomplete outcome data (attrition bias) Adverse events - subjective	Low risk	Assessment and reporting of outcome appears complete.
Selective reporting (reporting bias)	Unclear risk	No protocol available
Other bias	Low risk	No potential biases were apparent that do not correspond to the above categories (including study-specific problems such as carryover in cross-over trials, more general problems in study conduct such as contamination between intervention arms, or that a study is claimed to be fraudulent).

Xu 2008
Study characteristics

Methods	<p>Study design: parallel RCT</p> <p>Study location: China</p> <p>Study dates: enrolment June 2003 to June 2005.</p> <p>Recruitment: patients recruited at Nanfang Hospital, Guangzhou, China. Details of recruitment process not reported.</p> <p>Number screened / eligible: NR/NR</p> <p>Inclusion criteria: diagnosed as advanced or metastatic colorectal cancer; Karnofsky\geq60; acceptable laboratory data including electrocardiograph, routine blood tests, liver function tests; measurable nidus by imaging examinations or physical checkup; expected survival life \geq3 months; patients have not received the chemotherapy in which the regimens include oxaliplatin.</p>
---------	---

Xu 2008 (Continued)

Exclusion criteria: not reported.

Diagnostic criteria for inclusion/exclusion: confirmed diagnosis of advanced colorectal cancer by histopathology.

Participants

Number randomised: 53; *Coriolus versicolor* (PSK) 27; control 26

Baseline imbalances: paper states that groups are comparable and the clinical status elements at baseline in Table 1 do not differ between groups.

Age: PSK 64.3 ± 11.3 years; placebo 57.6 ± 10.7 years: overall median = 61 years, range 41-71 years

Sex: total male n = 31 (58%)

Cancer type: colorectal (no further details)

Cancer removed or present: unclear

If cancer was present, was it local or metastatic?: there was mention of metastases (liver, lung, bone, abdomen, pelvis, lymph nodes, local recurrence)

What was the aim of chemo/radiotherapy (if applicable)? unclear

Withdrawals and exclusions: not reported.

Interventions

***Coriolus versicolor* intervention:** Yunzhi [PSK] polysaccharide capsules 6 g/day, continuous oral administration for over one year plus chemotherapy as below

Control intervention: chemotherapy alone

Chemotherapy regimen: XELOX regimen: oxaliplatin 130 mg/m² intravenous infusion for 2 hours on the first day, capecitabine 2 000 mg/m² taken orally with morning and evening meal from the first day to the 14th day. 21 days are defined as a cycle. All patients received 3 to 8 cycles of chemotherapy

Planned length of treatment: over 1 year

Setting: not described

Co-interventions: not described

Outcomes

1. Overall survival
2. Complete remission (CR)
3. Partial remission (PR)
4. Stable disease (SD)
5. Progression (PD)
6. Quality of life (ECOG PS score, 0-5, lower is better)
7. Adverse events

Planned length of follow-up from treatment initiation: not reported

Time points: reported at 3 years with the exception of Quality of life which was quote: "evaluated after 3 cycles of chemotherapy" and the Response Evaluation Criteria in Solid Tumors (RECIST) factors (i.e., CR, PR, SD, PD), which were "evaluated after at least 3 cycles of chemotherapy".

Other outcomes: Effective rate (RR)=CR+PR, clinical benefit rate (CBR) = CR+PR+SD. Time to disease progression (TTP). Duration of overall survival.

Adverse event assessment: quote: "Adverse events are evaluated according to the National Cancer Institute Common Toxicity Criteria. The study assessed nausea, vomiting, bone marrow suppression tox-

Xu 2008 (Continued)

icity, hematotoxicity, neurotoxicity and non-hematological toxicity." The timing of the AEs is not described, and the total number of people with any AE, or with any SAEs, is not given. Adverse events are reported according to the numbers of each events occurring in each group. In the Yunzhi group there were a total of 51 AEs and in the control group there were a total of 112 adverse events.

Declaration of interest: none declared

Risk of bias

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No details reported.
Allocation concealment (selection bias)	Unclear risk	No details reported.
Blinding of participants and personnel (performance bias) Survival	Low risk	No blinding however no likely influence of unblinding upon survival
Blinding of participants and personnel (performance bias) Disease free survival/recurrence/response	Low risk	No blinding however no likely effect upon disease progression or recurrence
Blinding of participants and personnel (performance bias) Adverse events - subjective	High risk	No blinding and effect upon experience of adverse events at high risk of bias
Blinding of participants and personnel (performance bias) Adverse events - objective	Unclear risk	No blinding and effect upon adverse events unclear
Blinding of participants and personnel (performance bias) Quality of life	High risk	No blinding and effect upon quality of life at high risk of bias
Blinding of outcome assessment (detection bias) Survival	Low risk	No blinding of outcome assessors reported however low risk of bias in ascertainment of death
Blinding of outcome assessment (detection bias) Disease free survival/recurrence/response	Unclear risk	No blinding and unclear how assessment carried out.
Blinding of outcome assessment (detection bias)	High risk	No blinding and assessment of outcomes requiring judgment at high risk of bias.

Xu 2008 (Continued)

Adverse events - subjective

Blinding of outcome assessment (detection bias) Adverse events - objective	Unclear risk	No blinding and unclear how outcome assessment carried out.
Blinding of outcome assessment (detection bias) Quality of life	High risk	No blinding and assessment of outcomes requiring judgment at high risk of bias.
Incomplete outcome data (attrition bias) Survival	Unclear risk	Unclear processes for assessment and whether assessment was complete.
Incomplete outcome data (attrition bias) Disease free survival/recurrence/response	Unclear risk	Unclear processes for assessment and whether assessment was complete.
Incomplete outcome data (attrition bias) Quality of life	Low risk	Outcome appears to have been assessed on all participants and presented fully.
Incomplete outcome data (attrition bias) Adverse events - objective	Unclear risk	Unclear processes for assessment and whether assessment was complete.
Incomplete outcome data (attrition bias) Adverse events - subjective	Unclear risk	Unclear processes for assessment and whether assessment was complete.
Selective reporting (reporting bias)	Unclear risk	No protocol available.
Other bias	Low risk	No potential biases were apparent that do not correspond to the above categories (including study-specific problems such as carryover in cross-over trials, more general problems in study conduct such as contamination between intervention arms, or that a study is claimed to be fraudulent).

Characteristics of studies awaiting classification *[ordered by study ID]*

JPRN-UMIN000004351

Methods	Parallel Randomised
Participants	Adults with colon cancer
Interventions	FOLFOX4

JPRN-UMIN000004351 (Continued)

	FOLFOX6
	FOLFOX/Krestin
Outcomes	Frequency of neutropenia
	Other adverse events
	Medication adherence
	QOL
Notes	OPEN PUBLIC RECRUITING (as of 19/10/2012)

JPRN-UMIN000005286

Methods	Parallel Randomised
Participants	Adults with gastric and colorectal cancer clinical stage II/III
Interventions	TS-1 chemotherapy alone group
	TS-1 with PSK group
Outcomes	Transition of PSK and induction of infiltration of cytotoxic T lymphocytes into primary tumour
Notes	COMPLETED (as of 09/08/2016)

JPRN-UMIN000005484

Methods	Parallel Randomised
Participants	Adults with colorectal cancer
Interventions	Group A (standard therapy group:UFT/LV 6M)
	Group B (trial therapy group: PSK/UFT/LV 6M).
	Group C (trial therapy group: PSK/UFT/LV 12M)
Outcomes	3 year disease-free survival rate
	Survival time
	Adverse event rate
	Completion rate
Notes	COMPLETED (as of 28/10/2018)

JPRN-UMIN000006134

Methods	Parallel Randomised
---------	---------------------

JPRN-UMIN000006134 (Continued)

Participants	Adults with colon cancer
Interventions	Group A: mFOLFOX6 Group A': XELOX Group B: mFOLFOX6(or XELOX)/Krestin
Outcomes	The percentage of patients who complete scheduled treatment Adverse events IL-12 and the number of NK cells in peripheral blood
Notes	TERMINATED (as of 16/07/2014)

JPRN-UMIN000006541

Methods	Parallel Randomised
Participants	Adults with colon cancer
Interventions	Group A (capecitabine group) Group B (capecitabine/PSK group)
Outcomes	Adverse events rate 3 year disease-free survival 3 year relapse-free survival 3 year overall survival Compliance QOL
Notes	Complete: follow-up continuing (as of 02/04/2019)

JPRN-UMIN000007252

Methods	Parallel Randomised
Participants	Adults with colon cancer
Interventions	Group A(XELOX) Group B(XELOX+PSK)
Outcomes	Peripheral neuropathy as adverse event frequency Time to the peripheral neuropathy as adverse event Rate of treatment accomplishment Tolerated dose

JPRN-UMIN000007252 (Continued)

	Disease-free survival time
	Other adverse events
Notes	NO LONGER RECRUITING (as of 16/05/2017)

JPRN-UMIN000010046

Methods	Parallel Randomised
Participants	Adults with colorectal cancer
Interventions	1)Curative resection 2)UFT (Stage II) or UFT/LV (Stage III) for 1 year 1)Curative resection 2)UFT (Stage II) or UFT/LV (Stage III) combined with PSK for 1 year
Outcomes	3 year disease-free survival
Notes	OPEN PUBLIC RECRUITING (as of 09/09/2013)

NCT00209742

Methods	Parallel Randomised
Participants	Adults with histological stage III colorectal cancer
Interventions	Drug: UFT Drug: USEL/Leucovorin Drug: Krestin
Outcomes	3-year disease-free survival rate Dose intensity (compliance) 5-year disease-free survival rate 3- and 5-year survival rate Incidence of other adverse drug reactions QOL
Notes	STATUS UNKNOWN (as of 26/05/2010)

NCT00497107

Methods	Parallel Randomised
---------	---------------------

NCT00497107 (Continued)

Participants	Adults with histological stage IIIa/IIIb colorectal cancer
Interventions	Drug: UFT, Calcium Folate Drug: UFT + Calcium Folate + PSK
Outcomes	Disease-free survival Overall survival Compliance Adverse events QOL Tumour markers
Notes	STATUS UNKNOWN (as of 31/07/2008)

Ogawa 2021

Methods	Randomised Parallel
Participants	Patients with high-risk stage II/III colorectal cancer
Interventions	6 months of UFT/LV 6 months UFT/LV+PSK 12 months UFT/LV+PSK
Outcomes	3-year disease-free survival
Notes	

NK cells: natural killer cells; **PSK:** Polysaccharide Krestin **QoL:** quality of life.

DATA AND ANALYSES
Comparison 1. Adjuvant Coriolus versicolor vs no adjunctive treatment

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 Survival	5		Risk Ratio (M-H, Random, 95% CI)	Subtotals only
1.1.1 Survival at 1 year	1	448	Risk Ratio (M-H, Random, 95% CI)	1.02 [0.99, 1.05]
1.1.2 Survival at 3 years	4	958	Risk Ratio (M-H, Random, 95% CI)	1.04 [0.94, 1.15]

***Coriolus (Trametes) versicolor* mushroom to reduce adverse effects from chemotherapy or radiotherapy in people with colorectal cancer (Review)**

ADDITIONAL TABLES

Table 1. Included studies: cancer type, stage and treatment regimen

Study	Type of cancer	Included patients (as reported)	Surgery	Radiotherapy	Post-surgery, pre-PSK treatment	PSK and chemotherapy	Comparison	Duration
Ito 2004	Colon	Stage III (Dukes C)	macroscopic curative resection		5-FU 48-h IV infusion at a dose of 1,000 mg per m ² weekly for 3–4 weeks	Oral PSK 3g/day from the 29th postoperative day for 4 weeks followed by 4-week oral 5-FU treatment (200 mg/day)	oral 5-FU chemotherapy (200 mg per day) at 4-week intervals	10 courses (10 months)
Mitomi 1992	Colorectal	Stage II and III (Any TN1,2,3 M0 T4N0M0)	macroscopic curative resection		Mitomycin C (6mg/m ²) IV on day of and day after surgery	Oral PSK 3g/day for 3 years plus oral 5-FU (200mg/day) for 6 months	oral 5-FU (200mg/day) for 6 months	3 years
Ohwada 2004	Colorectal	Stage II or III	macroscopic curative resection		Mitomycin C (bolus injections of 12 and 8mg/m ²) on post-operative days 1 and 2 respectively	Oral PSK (3g/day) and UFT (300 mg/day), starting 2 weeks after surgery and continuing	UFT (300 mg/day), starting 2 weeks after surgery and continuing	2 years or until recurrence
Sadahiro 2010	Rectal	Stage II and III (cT3-T4, Tx N+, M0)	pre-surgery	Preoperative CRT. External beam RT for a total dose of 20 Gy, 5 days a week for two weeks		PSK 3.0 g/day in 3 daily doses plus oral S-1 80 mg/m ² /day in 2 daily doses for 4 weeks until 3 days before surgery	oral S-1 (Taiho Pharmaceutical Co., Japan) 80 mg/m ² /day in 2 daily doses for 4 weeks until 3 days before surgery	4 weeks
Shichonoh 2013	Colorectal	Stage III	curative resection			UFT+LV+PSK 28 days/5 weeks for 6 months, then UFT+PSK for 12	UFT+LV 28 days/5 weeks for 6 months, then UFT for 12 months	Up to 18 months

Table 1. Included studies: cancer type, stage and treatment regimen (Continued)

				months (started within 6 months of surgery)		
Sugimoto 2012	Colorectal	Stage II and III (high-risk stage II (T3–4N0M0) or stage III (T1–4N1–3M0))	curative resection	PSK (3 g/day) plus UFT (300 mg/m ² day) and LV (75 mg/day) starting 4~8 weeks after surgery and continuing for 6 months or until recurrence (5 days-on/2 days-off schedule)	UFT (300 mg/m ² day) and LV (75 mg/day) starting 4~8 weeks after surgery and continuing for 6 months or until recurrence (5 days-on/2 days-off schedule)	6 months or until recurrence
Xu 2008	Colorectal	Stage III and IV		Yunzhi polysaccharide (PSK) capsules 6 g/day for continuous oral administration plus XELOX regimen: oxaliplatin 130 mg/m ² intravenous infusion for 2 hours and capecitabine 2 000 mg/m ² from 1 day for a total of 14 days; 21 days is a course of treatment.	XELOX regimen: oxaliplatin 130 mg/m ² intravenous infusion for 2 hours and capecitabine 2 000 mg/m ² from 1 day for a total of 14 days; 21 days is a course of treatment.	3-8 cycles (median 4)

Appendix 2. Assessment of risk of bias

Risk of bias in randomised trials

Extracted from the *Cochrane Handbook for Systematic Reviews of Interventions* (<http://handbook.cochrane.org/>).

Table 8.5.d: Criteria for judging risk of bias in the 'Risk of bias' assessment tool

RANDOM SEQUENCE GENERATION	
Selection bias (biased allocation to interventions) due to inadequate generation of a randomised sequence.	
Criteria for a judgement of 'low risk' of bias	<p>The investigators describe a random component in the sequence generation process such as:</p> <ul style="list-style-type: none"> · referring to a random number table; · using a computer random number generator; · coin tossing; · shuffling cards or envelopes; · throwing dice; · drawing of lots; · minimisation*. <p>*Minimisation may be implemented without a random element, and this is considered to be equivalent to being random.</p>
Criteria for the judgement of 'high risk' of bias	<p>The investigators describe a non-random component in the sequence generation process. Usually, the description would involve some systematic, non-random approach, for example:</p> <ul style="list-style-type: none"> · sequence generated by odd or even date of birth; · sequence generated by some rule based on date (or day) of admission; · sequence generated by some rule based on hospital or clinic record number. <p>· other non-random approaches happen much less frequently than the systematic approaches mentioned above and tend to be obvious. They usually involve judgement or some method of non-random categorisation of participants, for example:</p> <ul style="list-style-type: none"> · allocation by judgement of the clinician; · allocation by preference of the participant; · allocation based on the results of a laboratory test or a series of tests; · allocation by availability of the intervention.
Criteria for the judgement of 'unclear risk' of bias	Insufficient information about the sequence generation process to permit judgement of 'low risk' or 'high risk'.
ALLOCATION CONCEALMENT	
Selection bias (biased allocation to interventions) due to inadequate concealment of allocations prior to assignment.	
Criteria for a judgement of 'low risk' of bias	<p>Participants and investigators enrolling participants could not foresee assignment because one of the following, or an equivalent method, was used to conceal allocation:</p> <ul style="list-style-type: none"> · central allocation (including telephone, web-based and pharmacy-controlled randomisation);

(Continued)

- sequentially numbered drug containers of identical appearance;
- sequentially numbered, opaque, sealed envelopes.

Criteria for the judgement of 'high risk' of bias

Participants or investigators enrolling participants could possibly foresee assignments and thus introduce selection bias, such as allocation based on:

- using an open random allocation schedule (e.g. a list of random numbers);
- assignment envelopes were used without appropriate safeguards (e.g. if envelopes were unsealed or nonopaque or not sequentially numbered);
- alternation or rotation;
- date of birth;
- case record number;
- any other explicitly unconcealed procedure.

Criteria for the judgement of 'unclear risk' of bias

Insufficient information to permit judgement of 'low risk' or 'high risk'. This is usually the case if the method of concealment is not described or not described in sufficient detail to allow a definite judgement – for example if the use of assignment envelopes is described, but it remains unclear whether envelopes were sequentially numbered, opaque and sealed.

BLINDING OF PARTICIPANTS AND PERSONNEL

Performance bias due to knowledge of the allocated interventions by participants and personnel during the study.

Criteria for a judgement of 'low risk' of bias

Any one of the following:

- no blinding or incomplete blinding, but the review authors judge that the outcome is not likely to be influenced by lack of blinding;
- blinding of participants and key study personnel ensured, and unlikely that the blinding could have been broken.

Criteria for the judgement of 'high risk' of bias

Any one of the following:

- no blinding or incomplete blinding, and the outcome is likely to be influenced by lack of blinding;
- blinding of key study participants and personnel attempted, but likely that the blinding could have been broken, and the outcome is likely to be influenced by lack of blinding.

Criteria for the judgement of 'unclear risk' of bias

Any one of the following:

- insufficient information to permit judgement of 'low risk' or 'high risk';
- the study did not address this outcome.

BLINDING OF OUTCOME ASSESSMENT

Detection bias due to knowledge of the allocated interventions by outcome assessors.

Criteria for a judgement of 'low risk' of bias

Any one of the following:

- no blinding of outcome assessment, but the review authors judge that the outcome measurement is not likely to be influenced by lack of blinding;
- blinding of outcome assessment ensured, and unlikely that the blinding could have been broken.

Criteria for the judgement of 'high risk' of bias

Any one of the following:

(Continued)

- no blinding of outcome assessment, and the outcome measurement is likely to be influenced by lack of blinding;
- blinding of outcome assessment, but likely that the blinding could have been broken, and the outcome measurement is likely to be influenced by lack of blinding.

Criteria for the judgement of 'unclear risk' of bias

- Any one of the following:
- insufficient information to permit judgement of 'low risk' or 'high risk';
 - the study did not address this outcome.

INCOMPLETE OUTCOME DATA

Attrition bias due to amount, nature or handling of incomplete outcome data.

Criteria for a judgement of 'low risk' of bias

- Any one of the following:
- no missing outcome data;
 - reasons for missing outcome data unlikely to be related to true outcome (for survival data, censoring unlikely to be introducing bias);
 - missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups;
 - for dichotomous outcome data, the proportion of missing outcomes compared with the observed event risk is not enough to have a clinically relevant impact on the intervention effect estimate;
 - for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes not enough to have a clinically relevant impact on observed effect size;
 - missing data have been imputed using appropriate methods.

Criteria for the judgement of 'high risk' of bias

- Any one of the following:
- reason for missing outcome data likely to be related to true outcome, with either imbalance in numbers or reasons for missing data across intervention groups;
 - for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk enough to induce clinically relevant bias in intervention effect estimate;
 - for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes enough to induce clinically relevant bias in observed effect size;
 - 'as-treated' analysis done with substantial departure of the intervention received from that assigned at randomisation;
 - potentially inappropriate application of simple imputation.

Criteria for the judgement of 'unclear risk' of bias

- Any one of the following:
- insufficient reporting of attrition/exclusions to permit judgement of 'low risk' or 'high risk' (e.g. number randomised not stated, no reasons for missing data provided);
 - the study did not address this outcome.

SELECTIVE REPORTING

Reporting bias due to selective outcome reporting.

(Continued)

Criteria for a judgement of 'low risk' of bias	<p>Any of the following:</p> <ul style="list-style-type: none"> · the study protocol is available and all of the study's pre-specified (primary and secondary) outcomes that are of interest in the review have been reported in the pre-specified way; · the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were pre-specified (convincing text of this nature may be uncommon).
Criteria for the judgement of 'high risk' of bias	<p>Any one of the following:</p> <ul style="list-style-type: none"> · not all of the study's pre-specified primary outcomes have been reported; · one or more primary outcomes is reported using measurements, analysis methods or subsets of the data (e.g. subscales) that were not pre-specified; · one or more reported primary outcomes were not pre-specified (unless clear justification for their reporting is provided, such as an unexpected adverse effect); · one or more outcomes of interest in the review are reported incompletely so that they cannot be entered in a meta-analysis; · the study report fails to include results for a key outcome that would be expected to have been reported for such a study.
Criteria for the judgement of 'unclear risk' of bias	Insufficient information to permit judgement of 'low risk' or 'high risk'. It is likely that the majority of studies will fall into this category.

OTHER BIAS

Bias due to problems not covered elsewhere in the table.

Criteria for a judgement of 'low risk' of bias	The study appears to be free of other sources of bias.
Criteria for the judgement of 'high risk' of bias	<p>There is at least one important risk of bias. For example, the study:</p> <ul style="list-style-type: none"> · had a potential source of bias related to the specific study design used; or · has been claimed to have been fraudulent; or · had some other problem.
Criteria for the judgement of 'unclear risk' of bias	<p>There may be a risk of bias, but there is either:</p> <ul style="list-style-type: none"> · insufficient information to assess whether an important risk of bias exists; or · insufficient rationale or evidence that an identified problem will introduce bias.

Appendix 3. Methods planned but not used in this review

Unit of analysis issues

For individual trials, the unit of analysis will be the individual patient. In the case of including cluster-randomised study designs, the unit of analysis will be the cluster. We will extract data if the authors have adjusted for the sample size in each cluster, so that it is appropriately weighted in the following analysis. For studies in which control of clustering is not performed or reported adequately by the authors (after we have contacted them), and individual patient data are not available, we will correct for the intervention effects of cluster-RCTs by reducing the size of each trial to its 'effective sample size', which is the number of the original sample size divided by the 'design effect'. We will calculate the design effect as $1 + (M-1) \times ICC$, where M is the average cluster size and ICC is the intracluster correlation coefficient, as described in chapter 16.3.4 in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011).

Dealing with missing data

We will contact study authors to provide missing data. Where this proves unsuccessful, we will investigate the potential impact of the missing data. If trials reported the number of patients with data missing for the primary outcome, we will take a worst-case scenario approach to data analyses, that is, taking those with missing data in the treatment group as treatment failures, while taking those with missing data in the control group as treatment successes (Gamble 2005). We will compare per protocol analysis of available data with the analysis incorporating missing data. If the effect estimate is in the same direction and there is a significant difference between groups, we will be able to make a conclusion with more confidence. If the effect estimates from the two analyses are different, then we will need to interpret the findings with more caution and make a more conservative conclusion about the treatment effect.

HISTORY

Protocol first published: Issue 2, 2016

CONTRIBUTIONS OF AUTHORS

Drafting of the protocol: Janine Leach, Jianping Liu, Karen Pilkington, Dawn Storey, Lida Teng.

Development of search strategies and conduct of searches: Karen Pilkington, Lida Teng, Xin Yan Jin, Jianping Liu.

Development of data extraction template: Karen Pilkington, L. Susan Wieland, Dawn Storey.

Selection and translation of trials, extraction of data: Karen Pilkington, L. Susan Wieland, Lida Teng, Xin Yan Jin, Jianping Liu.

Data entry into RevMan: L. Susan Wieland, Karen Pilkington.

Conduct and interpretation of the analysis: L. Susan Wieland, Karen Pilkington.

Preparation and editing of the review: Karen Pilkington, L. Susan Wieland, Lida Teng, Xin Yan Jin, Dawn Storey, Jianping Liu.

DECLARATIONS OF INTEREST

Karen Pilkington: none known

L. Susan Wieland: none known

Lida Teng: none known

Xin Yan Jin: none known

Jianping Liu: none known

SOURCES OF SUPPORT

Internal sources

- Innovative Research Team of Beijing University of Chinese Medicine, China

Jianping Lui's work on the review was partially supported by an internal grant (No. 2011-CXTD-09)

External sources

- National Center for Complementary and Integrative Health (NCCIH) of the US National Institutes of Health (www.nccih.nih.gov), USA

Jianping Lui's work on the review was partially funded by grant number R24 AT001293 (NCCIH)

The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We amended the review title to more clearly show the focus on adverse event reduction and to include the current preferred name for *Coriolus* (*Trametes*).

We amended the objectives to clarify that *Coriolus* was to be used adjunctively with chemotherapy or radiotherapy (and to match the inclusion criteria).

***Coriolus* (*Trametes*) *versicolor* mushroom to reduce adverse effects from chemotherapy or radiotherapy in people with colorectal cancer (Review)**

95

We amended adverse effect to adverse event in describing the data extracted and analysed in view of the lack of reporting of causality in the studies.

For searching of the Japanese databases, we searched only Ichushi Web (<http://www.jamas.or.jp>), web version of Igaku Chuou Zasshi (Japana centra revuo medicina). The clinical trial registration site of Japan UMIN-CTR is included in the WHO-clinical trial registration site. The remaining two databases listed in the protocol were not found to be appropriate for searching for randomised controlled trials. Searching of the US National Cancer Institute was not carried out as the trials are included on existing trials databases nor was Current Controlled Trials searched as this website is not longer available. BIOSIS Previews could only be searched to 2008 .

We had planned to contact study authors and manufacturers for unpublished trials and any missing data. We attempted to do so, but it was difficult to locate current contact details for study authors, and we did not obtain any responses while the Japanese manufacturer had discontinued the product used in the included trials .

We changed examples in the text of other sources of risk of bias to more closely conform to the description of this category in [Appendix 2](#).

We added that two review authors independently assessed all estimates of effect for certainty of evidence using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.
