

## 1 **Abstract**

2 Coordinated cell movement is a fundamental process in organ formation. During heart  
3 development, bilateral myocardial precursors collectively move towards the midline  
4 (cardiac fusion) to form the primitive heart tube. Along with extrinsic influences such as  
5 the adjacent anterior endoderm which are known to be required for cardiac fusion, we  
6 previously showed that the platelet-derived growth factor receptor alpha (Pdgfra) is also  
7 required. However, an intrinsic mechanism that regulates myocardial movement  
8 remains to be elucidated. Here, we uncover an essential intrinsic role in the myocardium  
9 for the phosphoinositide 3-kinase (PI3K) intracellular signaling pathway in directing  
10 myocardial movement towards the midline. *In vivo* imaging reveals that in PI3K-inhibited  
11 zebrafish embryos myocardial movements are misdirected and slower, while midline-  
12 oriented dynamic myocardial membrane protrusions become unpolarized. Moreover,  
13 PI3K activity is dependent on and genetically interacts with Pdgfra to regulate  
14 myocardial movement. Together our findings reveal an intrinsic myocardial steering  
15 mechanism that responds to extrinsic cues during the initiation of cardiac development.  
16

## 1 **Introduction**

2

3           During organogenesis, cell progenitor populations often need to move from their  
4 origin of specification to a new location in order to form a functional organ. Deficient or  
5 inappropriate movement can underlie congenital defects and disease. Directing these  
6 movements can involve extrinsic factors such as chemical and mechanical cues from  
7 neighboring tissues and the local environment as well as intrinsic mechanisms such as  
8 intracellular signaling and polarized protrusions (1). Progenitor cell movement occurs  
9 during cardiac development, where myocardial cells are specified bilaterally on either  
10 side of the embryo (2). To form a single heart that is centrally located, these bilateral  
11 populations must move to the midline and merge (3, 4). As they move, myocardial cells  
12 undergo a mesenchymal-to-epithelial (MET) transition forming intercellular junctions and  
13 subsequently moving together as an epithelial collective (5-9). This process is known as  
14 cardiac fusion and occurs in all vertebrates (10, 11).

15           External influence from the adjacent endoderm is essential for the collective  
16 movement of myocardial cells towards the midline. Mutations in zebrafish and mice  
17 which inhibit endoderm specification or disrupt endoderm morphogenesis result in  
18 cardia bifida – a phenotype in which the bilateral myocardial populations fail to merge  
19 (9, 12-21). Similar phenotypes also occur in chicks and rats when the endoderm is  
20 mechanically disrupted (22-24). Studies simultaneously observing endoderm and  
21 myocardial movement have found a correlation between the movements of these two  
22 tissues, suggesting a model in which the endoderm provides the mechanical force that

1 pulls myocardial cells towards the midline (24-27). Yet, these correlations do not occur  
2 at all stages of cardiac fusion, indicating that myocardial cells may also use intrinsic  
3 mechanisms to actively move towards the midline. Indeed, recent studies revealing a  
4 role for the receptor tyrosine kinase, platelet-derived growth factor receptor alpha  
5 (Pdgfra) in the movement of myocardial cells have suggested a paracrine chemotaxis  
6 model, in which the myocardium senses chemokine signals from the endoderm and  
7 responds to them (28). However, the existence and identity of these intrinsic myocardial  
8 mechanisms remain to be fully elucidated.

9         We have sought to identify the intracellular pathways downstream of Pdgfra that  
10 regulate the collective movement of the myocardium. The phosphoinositide 3-kinase  
11 (PI3K) pathway is known as an intracellular signaling mediator of receptor tyrosine  
12 kinases (e.g. Pdgfra). PI3K phosphorylates phosphatidylinositol (4,5)-bisphosphate  
13 (PIP2) to create phosphatidylinositol (3,4,5)-trisphosphate (PIP3), a regulator of cellular  
14 processes such as proliferation and cell migration (29). The PI3K pathway has been  
15 shown to be important for both individualistic cell migration such as in *Dictyostelium* and  
16 neutrophils (30, 31) as well as collective cell migration such as in the movement of  
17 border cells in *Drosophila* and the movement of the anterior visceral endoderm during  
18 mouse gastrulation (32, 33).

19         Using the advantages of external development and ease of live-imaging in the  
20 zebrafish model system (34), our studies reveal that myocardial PI3K signaling is  
21 required for proper directional movement towards the midline during cardiac fusion. In  
22 particular we find that inhibition of the PI3K pathway, throughout the embryo or only in

1 the myocardium, results in bilateral cardiomyocyte populations that fail to reach the  
2 midline (cardia bifida) or have only partially merged by the time wild-type myocardial  
3 cells are fully merged. High-resolution live imaging in combination with mosaic labeling  
4 further reveals that the orientation of myocardial membrane protrusions during cardiac  
5 fusion is dependent on PI3K signaling. Furthermore, we find that PI3K signaling and  
6 *Pdgfra* genetically interact to facilitate cardiac fusion. Altogether our work supports a  
7 model by which intrinsic *Pdgfra*-PI3K signaling regulates the formation of membrane  
8 protrusions that facilitate the collective movement of the myocardium towards the  
9 midline. Insight into the balance of extrinsic and intrinsic influences for directing  
10 collective movement of myocardial cells has implications for understanding a wide set of  
11 congenital and environmental cardiac defects as well as the pathogenic mechanisms of  
12 diseases broadly associated with collective movement.

13

## 1 **Results**

2

### 3 **The PI3K pathway is required for proper cardiac fusion**

4           In a search for intracellular signaling pathways that are important for cardiac  
5 fusion we examined the role of the phosphoinositide 3-kinase (PI3K) signaling pathway,  
6 by pharmacological inhibition of PI3K with LY294002 (LY) (35). Treatments were started  
7 at the bud-stage (10 hours post-fertilization - hpf), in order to exclude effects on  
8 mesodermal cells during gastrulation (36). In wild-type or DMSO-treated embryos,  
9 bilateral myocardial populations move towards the midline and merge to form a ring  
10 structure between 20-21 hpf, which corresponds to the 20-22 somite stage (s) (Fig. 1A,  
11 A', F). However, in LY-treated embryos myocardial movement is disrupted and the  
12 bilateral myocardial populations fail to properly merge by 22s (Fig. 1B, B', F, Suppl. Fig.  
13 1A-C, M). To rule out possible off-target phenotypic artifacts of LY (37), we exposed bud  
14 stage embryos to two other PI3K inhibitors, Dactolisib (Dac) or Pictilisib (Pic) (38, 39).  
15 Exposure to either of these inhibitors also causes cardiac fusion defects (Fig. 1C, C', F,  
16 G, Suppl. Fig. 1D-F, N; Fig. 1D, D', F, G, Suppl. Fig. 1G-I, O, respectively), as does the  
17 mRNA injection of a truncated form of p85 (Fig. 1E, E', F, G, Suppl. Fig. 1J-L, P), which  
18 acts as a dominant negative inhibitor of PI3K (dnPI3K) activity (40). Furthermore, to  
19 ensure our analysis was not complicated by a developmental delay, we used  
20 developmentally stage-matched embryos (somite stage) rather than time-matched  
21 embryos (hours post-fertilization; hpf) to assess cardiac fusion phenotypes (see Suppl.  
22 Fig. 2 for embryos analyzed at 20 hpf).

1           We also examined the morphology of the cardiac ring in PI3K-inhibited embryos  
2 and cellular processes known to be regulated by PI3K signaling. During the later stages  
3 of cardiac fusion as part of the subduction process, medial myocardial cells form a  
4 contiguous second dorsal layer (26) and develop epithelial polarity in which intercellular  
5 junction proteins such as ZO1 are localized to the outer-edge of the myocardium (5, 6)  
6 (Suppl. Fig. 3A-C). In PI3K-inhibited embryos, we found that myocardial cells form this  
7 second dorsal layer however, the localization of polarity markers and the tissue  
8 organization can appear mildly disorganized (Suppl. Fig. 3D-F). Furthermore, the PI3K  
9 signaling pathway is known to promote cell proliferation and cell survival (29) however,  
10 we did not find a difference in the number of cardiomyocytes in DMSO- or LY- treated  
11 embryos at 20s (Suppl. Fig. 3G-I). Similarly, no apoptotic cardiomyocytes were  
12 observed in DMSO- nor in 20  $\mu$ M LY- treated embryos (n = 17, 19 embryos,  
13 respectively from 3 biological replicates). Apoptotic cardiomyocytes were however  
14 observed in DNase-treated controls. These experiments reveal that PI3K signaling is  
15 required for proper cardiac fusion.

16

17 **The extent and duration of PI3K inhibition determines the penetrance and severity**  
18 **of cardiac fusion defects.**

19           PI3K-inhibited embryos display cardiac phenotypes at 22s that range from  
20 severe, in which the myocardial populations remain entirely separate (cardia bifida) (Fig.  
21 1G – red; examples - Suppl. Fig 1C, F, I, L), to more mildly affected hearts in which the  
22 myocardial populations form a U-shaped structure, having merged at the posterior but

1 not anterior end (Fig. 1G – orange; examples Suppl. Fig. 1B, E, H, K). A subset of the  
2 PI3K-inhibited embryos also appear phenotypically normal (~25% for 20  $\mu$ M LY, Fig. 1F,  
3 G) indicating incomplete penetrance. Increasing concentrations of PI3K inhibitor or  
4 dnPI3K mRNA increases the severity and penetrance of these phenotypes in a dose-  
5 dependent manner (Suppl. Fig. 1.). Similarly, we confirmed that LY inhibits PI3K activity  
6 in a dose-dependent manner, as measured by the ratio of phosphorylated AKT (pAKT)  
7 to AKT (Fig. 1H). AKT is phosphorylated as a direct consequence of PI3K activity (41).  
8 Thus, the severity and penetrance of cardiac fusion defects depends on the efficacy of  
9 PI3K inhibition.

10         Since differing modes of movement (9) as well as cellular processes such as  
11 MET (5, 6) and subduction (26) occur at different times during cardiac fusion, we also  
12 evaluated the developmental stages over which PI3K signaling is required. Short  
13 exposures (<3 hours) just prior to 22s or starting at bud stage had no effect on cardiac  
14 fusion. However, progressively longer times of exposure ending at 22s or starting at  
15 bud stage result in correspondingly more severe phenotypes and higher penetrance  
16 (Fig. 2A, B). These addition and wash-out experiments indicate that both the severity  
17 and penetrance of cardiac fusion phenotypes correlate with the duration of LY-  
18 incubation and not a specific developmental stage inside the 3-20s window. Thus,  
19 myocardial movement is responsive to both the levels and duration of PI3K signaling  
20 throughout cardiac fusion.

21

22

## 1 **PI3K signaling is required in the myocardium for proper cardiac fusion.**

2 Mutations affecting the specification or morphology of the anterior endoderm result  
3 in myocardial movement defects (13, 19, 42, 43), revealing a non-autonomous role for  
4 the anterior endoderm in cardiac fusion. However, when PI3K signaling is inhibited with  
5 15 or 25  $\mu$ M LY starting at bud stage we did not observe differences in the expression of  
6 endoderm markers such as *axial/foxa2* or *Tg(sox17:egfp)* compared to DMSO-treated  
7 embryos (Suppl. Fig 3J-L, N-P). Additionally, the overall morphology of the anterior  
8 endoderm appeared intact and the average anterior endoderm width was similar  
9 between PI3K-inhibited and DMSO-treated embryos (Suppl. Fig 3M, Q).

10 To determine if PI3K signaling is specifically required within the myocardium, as  
11 opposed to the endoderm, we created a myocardial-specific dominant negative  
12 transgenic construct, *Tg(myf7:dnPI3K)*. Our experimental design is outlined in Fig. 2C.  
13 In F1 embryos at 22s we observed embryos with normal cardiac rings and embryos with  
14 cardiac fusion defects (Fig. 2D-G'). Genotyping revealed that F1 embryos with normal  
15 cardiac rings (Fig. 2D-G) did not have the transgene (n = 71/71), while almost all sibling  
16 embryos with cardiac fusion defects (Fig. 2D'-G') were positive for the *Tg(myf7:dnPI3K)*  
17 transgene (n=40/41). And all embryos with the *Tg(myf7:dnPI3K)* transgene have a  
18 cardiac fusion defect (Fig. 2H). (F1 embryos from 4 independent founder pairs were  
19 analyzed since stable transgenics could not be propagated due to loss of viability, likely  
20 due to a requirement for PI3K signaling in cardiac contraction at later stages (44)).  
21 Statistical analysis reveals that the *Tg(myf7:dnPI3K)* transgene is significantly

1 associated with a cardiac fusion defect (Fisher's test  $p = 5.56 \times 10^{-31}$ ), indicating that  
2 PI3K signaling acts in the myocardium to regulate its movement during cardiac fusion.

3

4 **PI3K signaling is responsible for the steering and velocity of myocardial**  
5 **movements during cardiac fusion.**

6 Our analysis points to a role for PI3K signaling in the movement of myocardial  
7 cells. To identify the properties of myocardial movement regulated by PI3K signaling,  
8 we analyzed myocardial movement by performing *in vivo* time-lapse imaging with the  
9 *Tg(myf7:egfp)* transgene, which labels myocardial cells. A time-series using *hand2*  
10 expression to compare myocardial movement in DMSO-treated and PI3K-inhibited  
11 embryos reveals dramatic differences in myocardial movement beginning after 12s  
12 (Suppl. Fig. 4). We thus focused our time-lapse imaging on the 14-20s developmental  
13 window. In time-lapse movies of DMSO-treated embryos, myocardial cells display  
14 coherent medially directed movement (Fig. 3A-B, E, Suppl. Fig. 5A-A''', Video-1) with an  
15 average velocity of  $0.2334 \pm 0.007$  microns/min, which is consistent with previous  
16 studies (9, 28). In PI3K-inhibited embryos myocardial cells also display coherent,  
17 coordinated movement and do move in the general direction of the midline, however  
18 they make dramatically less progress (Fig. 3C-D, Suppl. Fig. 5B-B''', Video-2).  
19 Quantitative analysis of these myocardial cell tracks reveals that myocardial cells are  
20 slower ( $0.1879 \pm 0.008$  microns/min) and less efficient. Therefore, myocardial cells  
21 ultimately move less in LY-inhibited embryos compared to DMSO-treated embryos (Fig.  
22 3E, F, Video-3). Differences in velocity occur throughout cardiac fusion (Suppl. Fig. 5C).

1 However, the most dramatic difference between PI3K-inhibited and DMSO-treated  
2 myocardial cells is in the direction of their movement. Tracks of myocardial cells in  
3 DMSO-treated embryos are predominately oriented in a medial direction (average of  
4  $31.1 \pm 1.65$  degrees), while tracks in LY-treated embryos are mostly oriented in an  
5 angular anterior direction ( $60.6$  degrees  $\pm 1.73$ , p-value =  $2.77 \times 10^{-12}$ , Fig. 3G, H).  
6 Differences in directional movement occur mainly in the early stages of cardiac fusion  
7 when wild-type myocardial movement is mostly medial (Suppl. Fig. 5D). Together this  
8 analysis of myocardial cell tracks suggests that PI3K signaling is responsible for both  
9 steering and propelling myocardial cells towards the midline.

10

### 11 **Myocardial membrane protrusions are medially polarized by PI3K signaling**

12 The role of PI3K signaling in regulating the polarity of migratory protrusions in the  
13 dorsal epithelium in *Drosophila* and prechordal plate in zebrafish (36, 45) along with  
14 previous reports of the existence of myocardial membrane protrusions (7, 26), led us to  
15 next look for these protrusions in myocardial cells during cardiac fusion and to examine  
16 if they are disrupted in PI3K-inhibited embryos. To visualize membrane protrusions in  
17 the myocardium, we performed *in vivo* time-lapse imaging during cardiac fusion of  
18 embryos injected with *myl7:lck-egfp* plasmid DNA in order to mosaically label the  
19 plasma membrane of myocardial cells. Despite myocardial cells being connected via  
20 intercellular junctions (5, 28), we observed that the lateral edges of myocardial cells in  
21 wild-type/DMSO-treated embryos are highly dynamic; transitioning from appearing  
22 smooth and coherent to undulating and extending finger-like membrane protrusions

1 away from the cell (Fig. 4A-A''', Video-4). These protrusions are dynamic, actively  
2 extending and retracting, and are prevalent occurring on average  $20.3 \pm 6.7$  times per  
3 hour per cell and lasting for an average of  $2.3 \pm 0.6$  mins (Fig. 4A). In LY-treated  
4 embryos we observed similar membrane protrusions extending from myocardial cells  
5 (Fig. 4B, Video-4), which occur at a similar rate ( $17 \pm 7.4$  per hour per cell, p-value =  
6 0.36), but with slightly longer persistence ( $3.23 \pm 0.84$  mins, p-value = 0.008).

7 We further observed that in DMSO-treated embryos membrane protrusions occur  
8 predominantly in the medial direction ( $77.25 \pm 21.76\%$  of protrusions were in the  
9 forward direction, Fig. 4A-A''', C, D), suggesting an association with the medial  
10 movement of the myocardial tissue. In contrast, in LY-treated embryos myocardial  
11 membrane protrusions do not display the same medial polarity, instead extending from  
12 all sides of a myocardial cell equally (only  $46 \pm 11.6\%$  of protrusion were in the forward  
13 direction, Fig 4B-B''', C, D). The finding that myocardial membrane protrusions are  
14 medially polarized in wild-type embryos but not in PI3K-inhibited embryos where  
15 myocardial cells are misdirected and slower to reach the midline suggests that PI3K  
16 signaling helps to steer and propel myocardial cells towards the midline through the  
17 polarization of these active protrusions.

18

### 19 **PI3K signaling is regulated by *Pdgfra* during cardiac fusion**

20 The improperly directed myocardial cells in PI3K-inhibited embryos (Fig. 3) are  
21 reminiscent of the steering defects observed in *pdgfra* mutant embryos (28). This  
22 similarity led us to investigate whether *Pdgfra* activates PI3K signaling to regulate

1 myocardial movement. We found that PI3K activity as measured by the ratio of  
2 phospho-AKT to AKT levels (41), is severely diminished in *pdgfra* mutant embryos  
3 during cardiac fusion (Fig. 5A). Conversely, when *Pdgfra* activity is increased during  
4 cardiac fusion through the over-expression of *pdgf-aa*, PI3K activity is up-regulated (Fig.  
5 5B).

6 To determine if *Pdgfra*'s influence on PI3K activity is important for myocardial  
7 movement towards the midline, we examined whether these two genes genetically  
8 interact while regulating cardiac fusion. When *pdgfra* heterozygous mutant embryos are  
9 exposed to DMSO cardiac fusion occurs normally (Fig. 5D, F), even though there is a  
10 small reduction in PI3K activity (Fig. 5A). When wild-type embryos are exposed to 10 $\mu$ M  
11 LY, PI3K activity is modestly reduced (Fig. 1H) and a small percent of embryos display  
12 mild cardiac fusion defects (Average of  $10.9 \pm 7.39\%$  of 10 $\mu$ M LY-treated embryos  
13 display mild U-shaped cardiac fusion defects, n= 36, 3 replicates, Fig 5C, F). However,  
14 when *pdgfra* heterozygous mutant embryos are exposed to 10 $\mu$ M LY, there is a  
15 synergistic increase in both the severity and penetrance of cardiac fusion defects. 100%  
16 of *pdgfra* heterozygous embryos exposed to 10 $\mu$ M LY display cardiac fusion defects,  
17 with the majority of embryos displaying severe cardia bifida phenotypes (Fig. 5E, F).  
18 Together these results suggest that PDGF signaling activates PI3K activity to promote  
19 myocardial movement towards the midline.

20

21

## 1 Discussion

2

3 Our studies reveal an intrinsic PI3K-dependent mechanism by which the  
4 myocardium moves towards the midline during the formation of the primitive heart tube.  
5 Together with our previous studies revealing a role for the PDGF pathway in facilitating  
6 communication between the endoderm and myocardium (28), our current work  
7 suggests a model in which *Pdgfra* in the myocardium senses signals (PDGF ligands)  
8 from the endoderm and via the PI3K pathway directs myocardial movement towards the  
9 midline through the production of medially oriented membrane protrusions. While  
10 genetic and imaging studies in zebrafish and mice (5, 13, 18, 19, 25-27, 46, 47) along  
11 with embryological studies in chicks and rats (22-24, 48) have identified the importance  
12 of extrinsic influences – such as the endoderm and extracellular matrix, on myocardial  
13 movement to the midline, our studies using tissue-specific techniques identifies an  
14 active role for myocardial cells, providing insight into the balance of intrinsic and  
15 extrinsic influences that regulate the collective movement of the myocardial tissue  
16 during heart tube formation.

17 Specifically, we found a requirement for PI3K signaling in cardiac fusion which is  
18 complemented by previous studies in mice examining *Pten*, an antagonist of PI3K (29).  
19 *Pten* mutant mice also display *cardia bifida* (33), indicating that appropriate PIP3 levels  
20 and localization are required for proper cardiac fusion. Our spatial and temporal  
21 experiments further build on these studies by revealing a requirement for PI3K  
22 specifically in the myocardium and throughout the duration of cardiac fusion (Fig. 2). We

1 also observed a mild disorganization of the sub-cellular localization of intercellular  
2 junctions in the myocardium of PI3K-inhibited embryos (Suppl. Fig. 3). This finding is  
3 consistent with previous studies linking epithelial polarity to PI3K signaling (49).  
4 However, myocardial cells defective in apical-basal polarity still form a cardiac ring (50,  
5 51), suggesting that an apical-basal defect is unlikely to be the primary reason for  
6 myocardial movement defects. Instead, our studies showing that PI3K-inhibited  
7 myocardial cells move slower and most prominently are misdirected during the early  
8 stages of cardiac fusion indicate a role for PI3K signaling in the steering of myocardial  
9 movements medially towards the midline. Our finding that steering in PI3K-inhibited  
10 embryos is perturbed in the early stages of cardiac fusion is furthermore consistent with  
11 the different phases of myocardial movement identified by Holtzman et al. (9) and  
12 suggests that PI3K signaling could be part of a distinct molecular mechanism that drives  
13 these early medial phases of myocardial movement. We also found that similar to loss-  
14 of-function *pdgfra* mutants, inhibition of PI3K signaling causes defects in directional  
15 movement. However, inhibition of PI3K signaling affects myocardial velocity and  
16 efficiency (~ 20%  $\mu$ /min decrease in velocity, and a 25% decrease in efficiency  
17 compared to DMSO-treated embryos) more noticeably than *pdgfra* mutants, in which no  
18 significant difference in velocity or efficiency were detected (28). These differences  
19 could simply be a result of differences in the extent of PI3K inhibition by 20 $\mu$ M LY  
20 compared to extent of loss-of-*pdgfra* function by the *ref* mutation. Alternatively, similar to  
21 the role of PI3K signaling in the velocity of gastrulating mesoderm cells as well as in  
22 migrating *dictyostelium* and neutrophil cells (30, 31, 36, 52) these differences could also

1 indicate a *Pdgfra*-independent PI3K function in regulating the velocity of myocardial  
2 movement.

3 Myocardial membrane protrusions were postulated by De Haan et al. ~50 years  
4 ago as a mechanism by which myocardial cells move towards the midline (53). Here  
5 using mosaic membrane labeling of myocardial cells to visualize membrane protrusions,  
6 we have observed myocardial membrane protrusions that are oriented in the medial  
7 direction in a PI3K-dependent manner, confirming his hypothesis. These studies are  
8 complemented by previous studies in zebrafish which have observed myocardial  
9 protrusions prior to and after cardiac fusion (26, 54) as well as recent studies in the  
10 mice (7) indicating that these cellular processes are likely conserved. Indeed, similar  
11 observations of PI3K signaling orienting and stimulating protrusion formation in  
12 migrating *Dictyostelium* and neutrophil cells as well as in the collective movement of  
13 endothelial tip cells, the prechordal plate and the dorsal epithelium (30, 31, 36, 45, 55,  
14 56) support a conserved role for PI3K signaling in regulating protrusion formation.

15 However, the question of how active membrane protrusions facilitate the  
16 collective medial movement of the myocardium to the midline remains to be addressed.  
17 Our studies indicate that directionality and to a lesser extent velocity and efficiency are  
18 compromised, when membrane protrusions are improperly oriented in PI3K-inhibited  
19 embryos (Fig. 3). These observations could suggest that the observed membrane  
20 protrusions are force generating, similar to protrusions from leader cells in the lateral  
21 line or in endothelial and tracheal tip cells (57-59). Alternatively, these protrusions could  
22 act more like filopodia sensing extrinsic signals and the extracellular environment (60).

1 Future studies examining myocardial protrusions and their role in the biomechanical  
2 dynamics of the myocardium will help to elucidate the role of membrane protrusions in  
3 the collective movement of the myocardium during cardiac fusion.

4 Overall, our studies delineate a role for the PDGF-PI3K pathway in the  
5 mechanisms by which myocardial precursors sense and respond to extracellular signals  
6 to move into a position to form the heart. These mechanisms are likely relevant to other  
7 organ progenitors including neural crest cells, endothelial precursors, endodermal  
8 progenitors, and neuromasts, all of which must move from their location of specification  
9 to a different location for organ formation. Although varying in their morphogenesis,  
10 many of these movements are collective in nature. Indeed, a similar *Pdgfra*-PI3K  
11 signaling cassette is important in the collective directional migration of several organ  
12 progenitors including the migration of mesoderm and neural crest cells (36, 61-67).  
13 Receptor tyrosine kinase (RTK)-PI3K pathways are also important across several  
14 cardiac developmental processes, including epicardial development, cardiac neural  
15 crest addition, cardiomyocyte growth, cardiac fibroblast movement and cardiomyocyte  
16 contraction (44, 68-72). Similarly, PDGF-PI3K and more generally RTK-PI3K signaling  
17 cassettes are activated in several diseases including glioblastomas, gastrointestinal  
18 stromal tumors and cardiac fibrosis (73-76). Thus, the role of this RTK-PI3K cassette in  
19 sensing and responding to extracellular signals is likely to be broadly relevant to the  
20 etiology of a wide array of developmental processes as well as congenital diseases.

10 **Contributions:** R. Shrestha, T. McCann and J. Bloomekatz conceived of the project  
11 and experimental design. R. Shrestha, T. McCann, H. Saravanan, J. Lieberth, P. Koirala  
12 and J. Bloomekatz performed experimental studies. R. Shrestha, J. Bloomekatz and T.  
13 McCann prepared the manuscript.

14

15 **Competing interests**

16 The authors declare no competing interests

17

18 **Material Availability**

19 Materials not available commercially are available upon request to Dr. Joshua

20 Bloomekatz.

## 1 **Materials and methods**

2

### 3 **Zebrafish husbandry, microinjections and plasmid construction:**

4 All zebrafish work followed protocols approved by the University of Mississippi IACUC

5 (protocol #21-007). Wildtype embryos were obtained from a mixed zebrafish (*Danio*

6 *rerio*) AB/TL background. The following transgenic lines of zebrafish were used:

7 *Tg(myl7:eGFP)<sup>twu34</sup>* (RRID:ZFIN\_ZDB-GENO-050809-10)(77), *Tg(sox17:eGFP)<sup>ha01</sup>*

8 (ZFIN\_ZDB-GENO-080714-2)(78), *Tg(hsp70l:pdgfaa-2A-mCherry;cryaa:CFP)<sup>sd44</sup>*

9 abbreviated *hs:pdgfaa* (ZDB-GENO-170510-4), and *ref (pdgfra<sup>sk16</sup>)* (ZDB-GENO-

10 170510-2) (28). All embryos were incubated at 28.5 °C unless otherwise noted.

11 Transgenic *Tg(myl7:dnPI3K; Cryaa:CFP)* F0 founders were established using standard

12 Tol2-mediated transgenesis (79). F0 founders pairs were screened by intercrosses

13 looking for a high percentage of F1 embryos with CFP+ eyes and cardiac edema.

14 Stable transgenic lines could not be propagated due to loss of viability. Based on the

15 germline mosaicism of the F0 parents, only a proportion of the F1 embryos are

16 expected to have the transgene. Embryos from 4 different F0 pairs were analyzed for

17 cardiac fusion phenotypes. Due to germ-line mosaicism F1 embryos were genotyped

18 after *in situ* hybridization for the presence of the transgene using standard PCR

19 genotyping. Primer sequences are provided in Suppl. Table 1.

20 Truncated p85 (dnPI3K) capped mRNA was synthesized from the pBSRN3- $\Delta$ p85

21 construct (40) and injected at the 1-cell stage. To mosaically label cells in the

22 myocardium for protrusion imaging, *myl7:lck-eGFP* (30 ng/ $\mu$ l) DNA was injected along

1 with Tol2 transposase (40 ng/ $\mu$ l) into *Tg(myI7:eGFP)* heterozygous embryos at the 1  
2 cell stage and embryos were subsequently allowed to develop at 28.5 °C.

3 Plasmids were constructed by using gibson assembly (NEB, E2621) to transfer  
4 lck-eGFP (80) or a truncated version of p85 (40) into the middle-entry vector of the tol2  
5 gateway system (81), which were verified by sequencing. Primer sequences are  
6 provided in Suppl. Table 1. Then gateway recombination between p5E-myI7 promoter,  
7 the constructed middle-entry clones, p3E-polyA and either pDESTTol2pA2 (81) or  
8 pDESTTol2pA4-Cryaa:CFP (28) was used to produce plasmids containing *myI7:lck-*  
9 *eGFP* or *myI7:dnPI3K; Cryaa:CFP*, respectively.

10

#### 11 **Inhibitor treatments:**

12 The following inhibitors were used: LY294002 (LY, Millipore-Sigma 154447-36-6),  
13 Dactolisib (Dac, Millipore-Sigma 915019-65-7), and Pictilisib (Pic, Millipore-Sigma  
14 957054-30-7). For each treatment, inhibitors were freshly diluted serially from stocks  
15 such that the same percentage (0.1%) of DMSO (Goldbio 67-68-5, Millipore-Sigma 67-  
16 68-5) was added to 1X E3 in glass vials (Fisherbrand 03-339-22B). 0.1% DMSO was  
17 used as a control. 15 dechorionated embryos per vial were incubated in the dark at 28.5  
18 °C. In the course of these studies, we noticed that incubation with pharmacological  
19 PI3K-inhibitors caused a delay in trunk elongation and somite formation along with  
20 defects in cardiac fusion (Suppl. Fig. 2). To ensure our analysis was not obscured by  
21 a developmental delay, we used somite number to stage match embryos. PI3K-inhibited

1 embryos thus develop approximately 2-3 hours longer than DMSO-treated embryos,  
2 prior to analysis.

3

#### 4 **Immunoblot, Immunofluorescence, *in situ* hybridization:**

5 Embryos at 22s were prepared for immunoblots by deholking (82). Primary and  
6 secondary antibodies include phospho-AKT (1:2000, Cell Signaling 4060, RRID:  
7 AB\_2315049) and pan-AKT (1:2000, Cell Signaling 4691, RRID: AB\_915783), Anti-  
8 rabbit HRP-conjugated (1:5000, Cell Signaling 7074, RRID: AB\_2099233). pAKT and  
9 AKT immunoblots were visualized (Azure 600 Imaging system, Azure Biosystems) and  
10 quantified using ImageJ (83) by calculating the ratio of pAkt to Akt. Ratios were  
11 normalized to DMSO. To identify *pdgfra/ref* heterozygous and homozygous embryos,  
12 embryo trunks were clipped and genotyped as described (28). The body of the embryo  
13 including the heart was snapped frozen and stored at -80 °C. After genotyping, they  
14 were pooled via their genotype and analyzed via immunoblot. To activate *Pdgfra*,  
15 embryos expressing the *Tg(hsp701: pdgfaa-2A-mCherry)* transgene were heat-shocked  
16 at bud stage as described (28) and collected at 22s.

17 Immunofluorescence performed on transverse sections used standard  
18 cryoprotection, embedding and sectioning (46). Primary, secondary antibodies and dyes  
19 include: anti-GFP (1:1000, Abcam ab13970, RRID: AB\_300798), anti-ZO-1 (1:200,  
20 Thermo Fisher Scientific 33-9100, RRID: AB\_87181), donkey anti-chicken-488 (1:300,  
21 Thermo Fisher Scientific A32931TR, RRID: AB\_2866499), donkey anti-mouse-647  
22 (1:300, Thermo Fisher Scientific A32728, RRID:AB\_2633277). TUNEL was performed

1 using the Cell Death detection kit, TMR red (Millipore Sigma 12156792910). Addition of  
2 DNaseI was used to confirm we could detect apoptotic cells.

3 *In situ* hybridization was performed using standard protocols (Alexander et al.,  
4 1998), with the following probes: *myl7* (ZDB-GENE-991019–3), *axial* (ZDB-GENE-  
5 980526–404) and *hand2* (ZDB-GENE-000511–1). Images were captured with Zeiss  
6 Axio Zoom V16 microscope (Zeiss) and processed with ImageJ.

7

### 8 **Fluorescence Imaging:**

9 To analyze cardiac fusion (Fig. 1A'-E') *Tg(myl7:eGFP)* embryos were fixed,  
10 manually deyolked and imaged with a Leica SP8X microscope. To analyze the anterior  
11 endoderm (Suppl. Fig. 3N-P) *Tg(sox17: eGFP)* embryos were fixed and imaged with an  
12 Axio Zoom V16 microscope (Zeiss).

13 For live imaging, *Tg(myl7:eGFP)* embryos were exposed to DMSO or 20 $\mu$ M LY  
14 at bud stage and mounted at 12 somite stage as described (84). Mounted embryos  
15 were covered with 0.1% DMSO/20 $\mu$ M LY in Tricaine-E3 solution and imaged using a  
16 Leica SP8 X microscope with a HC PL APO 20X/0.75 CS2 objective in a chamber  
17 heated to 28.5 °C. GFP and brightfield stacks were collected approximately every 4 min  
18 for 3 hours. After imaging, embryos were removed from the mold and incubated for 24  
19 hrs in E3 media at 28.5 °C. Only embryos that appeared healthy 24 hours post imaging  
20 were used for analysis. The tip of the notochord was used as a reference point to  
21 correct embryo drift in the Correct 3D direct ImageJ plugin (85). Embryos were handled

1 similarly for imaging protrusions, except 15 confocal slices of 1  $\mu$ m thickness were  
2 collected every 1.5 min with a HC PL APO 40X/1.10 CS2 objective.

3

#### 4 **Image analysis:**

5 Embryonic length (Suppl. Fig. 2) was measured from the anterior tip of the head  
6 to the posterior tip of the tail of each embryo using the free-hand tool of ImageJ. The  
7 endoderm width was measured 300 microns anterior from the posterior point of  
8 intersection of the two sides of the endoderm. The distance between the *hand2*  
9 expressing domains was measured at three equidistant positions (~200 microns apart)  
10 along the anterior posterior axis. *Tg(myI7:eGFP)+* cardiomyocytes were counted from  
11 blinded and non-blinded 3D confocal images of 20s embryos from 4 biological replicates  
12 using the cell counter addon in ImageJ. No difference between the blinded (1) and non-  
13 blinded (3) replicates was detected.

14 For live imaging of cell movements – the mTrackJ addon in ImageJ (86) was  
15 used. 20-25 cells per embryo whose position could be determined at each timepoint  
16 were chosen from the two most medial columns of myocardial cells on each side of the  
17 embryos. From these tracks, cell movement properties including overall displacement,  
18 velocity (displacement/time), efficiency (displacement/distance) and direction  
19 ( $\text{atan}(\Delta y/\Delta x) \times 57.295$ ) were calculated. Rose plots in Fig. 3 display the direction of  
20 movement of the overall trajectory of individual cells. In these plots individual cells are  
21 grouped into 6 bins based on their net direction of movement; the length of each radial  
22 bar represents the percentage of cells in each bin.

1           For live imaging of myocardial membrane protrusions – stacks were processed in  
2 Leica LASX and/or Imaris Viewer (Bitplane) to position the medial edge to the right of  
3 the image. Videos of the myocardium were inspected frame by frame in ImageJ for a  
4 protrusion. Only cells that were not neighbored by other labeled cells on their medial  
5 and lateral edges were analyzed. The direction of protrusion was measured using the  
6 “straight line” function a line to draw a line from the bottom of the protrusion to the tip.  
7 All protrusions of each cell over the entire recording were measured. Graphs, cartoons  
8 and figures were created with Prism (Graphpad), Excel (Microsoft), and Indesign  
9 (Adobe).

10

#### 11 **Statistics and replication:**

12 All statistical analysis was performed in R or Prism (Graphpad). Sample sizes were  
13 determined based on prior experience with relevant phenotypes and standards within  
14 the zebrafish community. Deviation from the mean is represented as standard error  
15 mean or box-whisker plots. In box-whisker plots, the lower and upper ends of the box  
16 denote the 25<sup>th</sup> and 75<sup>th</sup> percentile, respectively, with a horizontal line denoting the  
17 median value and the whiskers indicating the data range. All results were obtained from  
18 at least three separate biological replicates, blinded and non-blinded. All replicates are  
19 biological. Samples were analyzed before biological sex is determined (87). Raw data  
20 and full p-values included in the source file.

21

22

## 1 **Legends**

2

3 **Fig. 1. The PI3K pathway is required for cardiac fusion. A-E** Dorsal views, anterior

4 to the top, of the myocardium labeled with *myl7* (A-E) at 22 somite stage (s) or

5 *Tg(myI7:egfp)* (A'-E') at 20s. In contrast to a ring of myocardial cells in DMSO-treated

6 embryos (A, A'), in embryos treated with PI3K inhibitors LY294002 (LY, B, B'),

7 Dactolisib (Dac, C, C'), or Pictilisib (Pic, D, D') at bud stage or injected with *dnPI3K*

8 mRNA (750pg) at the one-cell stage (E, E') cardiac fusion fails to occur properly with

9 embryos displaying either cardia bifida (B, C) or fusion only at the posterior end (D, E).

10 **F, G** Graphs depict the percentage (F) and range (G) of cardiac fusion defects in control

11 and PI3K-inhibited embryos. Dots represent the percent of embryos with cardiac defects

12 per biological replicate. Total embryos analyzed n = 37 (DMSO), 31 (20 $\mu$ M LY), 39

13 (40 $\mu$ M Dac), 38 (50 $\mu$ M Pic), 86 (*dnPI3K*). Blue – cardiac ring/normal; Orange – fusion

14 only at posterior end/mild phenotype, Red – cardia bifida/severe phenotype. **H**

15 Representative immunoblot and ratiometric analysis of phosphorylated Akt (pAkt) to Akt

16 protein levels in DMSO and LY treated embryos reveals a dose-dependent decrease in

17 PI3K activation. Bar graphs indicate mean  $\pm$  SEM, dots indicate pAKT/AKT ratio per

18 biological replicate, normalized to DMSO. Three biological replicates per treatment.

19 One-Way ANOVA tests – letter changes indicate differences of  $p < 0.05$  (F, H). Scale

20 bars, 40  $\mu$ m (A-E), 42  $\mu$ m (A'-E'). Raw data and full p-values included in the source file.

21

1 **Fig 2: PI3K is required in the myocardium throughout cardiac fusion. A, B**  
2 Graphical representation of the PI3K inhibitor addition (A) and wash-out (B) experiments  
3 used to determine the developmental stage over which PI3K is required. In (A) LY is  
4 added to embryos at different developmental stages and incubated until 22s, when  
5 cardiac fusion is assessed. In (B) LY is added at bud stage and washed-out at different  
6 developmental stages, after which embryos are incubated in normal media till 22s,  
7 when cardiac fusion is assessed. Bar graphs indicate the average proportion of  
8 embryos displaying different phenotypes. Blue – cardiac ring/normal; Orange – fusion  
9 only at posterior end/mild phenotype, Red – cardia bifida/severe phenotype. n = 45  
10 embryos per treatment condition from three biological replicates. **C** Schematic outlines  
11 experimental design to test requirement for PI3K in the myocardium. Pink – cells with  
12 the *Tg(myl7:dnPI3K)* transgene. F0 animals are mosaic for the transgene, while all cells  
13 in F1 embryos either have the transgene (pink) or do not (clear). The *myl7* promoter  
14 restricts *dnPI3K* expression to the myocardium in *Tg(myl7:dnPI3K)* embryos. **D-G**  
15 Dorsal view of the myocardium labeled with *myl7* in embryos at 22s from 4 different  
16 founder pairs (D-D', E-E', F-F', G-G'). F1 embryos without the *Tg(myl7:dnPI3K)*  
17 transgene (as determined by genotyping) display normal cardiac fusion (D-G, n = 23/24,  
18 16/16, 16/16, 16/16, per founder pair), while F1 siblings with the *Tg(myl7:dnPI3K)*  
19 transgene display cardiac fusion defects (D'-G', n = 6/6, 13/13, 11/11, 13/13), indicating  
20 that PI3K signaling is required in myocardial cells. **H** Graph indicating the average % of  
21 wild-type and *Tg(myl7:dnPI3K)+* embryos with cardiac fusion defects. Letter difference  
22 indicates a significant Fisher's exact test  $p = 5.56 \times 10^{-31}$ . Scale bar, 40 $\mu$ m.

1 **Fig 3: PI3K signaling regulates the medial movement and velocity of the**  
2 **myocardium during cardiac fusion. A-D** Time points from a representative time-lapse  
3 video of myocardial cells visualized with the *Tg(myl7:egfp)* transgene in embryos  
4 treated with DMSO (A, B, Video-1) or 20 $\mu$ M LY (C, D, Video-2) from bud - 22s. 3D  
5 reconstructions of confocal slices (A, C) reveal the changes in conformation and  
6 location of the myocardium at 3 major stages of cardiac fusion: early medial movement  
7 towards the embryonic midline (A-A', C-C'), posterior merging of bilateral populations  
8 (A'', C'') and anterior merging to form a ring (A''', C'''). Representative tracks (B, D) show  
9 the paths of a subset of myocardial cells over ~2.5 hr timelapse. Yellow dots indicate  
10 the starting point of each track. **E-H** Graphs depict box-whisker plots of the velocity (E),  
11 efficiency index (F) and angle of movement (H) of myocardial cells. The direction of  
12 movement is visualized by rose plots (G). Myocardial cells in PI3K-inhibited (LY-treated)  
13 embryos show an overall direction of movement that is angular (60-90 degrees) and is  
14 slower than in DMSO-treated embryos. Scale bar, 60 $\mu$ m. 96 and 125 cells were  
15 analyzed from five DMSO- and six 20 $\mu$ M LY- treated embryos, respectively. Two  
16 sample t-test, letter change indicates  $p < 0.05$ . Raw data and full p-values included in  
17 the source file.

18

1 **Fig 4: Myocardial membrane protrusions are misdirected in PI3K-inhibited**  
2 **embryos. A-B''''** timepoints from representative timelapse videos (see Video-4) of  
3 myocardial cells whose membrane has been labeled with *myl7:lck-eGFP* (black), medial  
4 to the right, in a DMSO- (A-A''') or a 20 $\mu$ M LY- (B-B''') treated embryo. Red arrowheads  
5 indicate representative protrusions, which are oriented medially, coincident with the  
6 direction of movement in DMSO-treated embryos (A-A''') but are oriented in all  
7 directions in LY-treated embryos (B-B'''). **C, D** Rose (C) and Bar (D) graphs displaying  
8 the orientation of membrane protrusions in DMSO- (left) or LY- (right) treated embryos.  
9 The length of each radial bar in (C) represents the percentage of protrusions in each  
10 bin. Bar graph displays the total percentage of forward or backward protrusions.  
11 Forward protrusions: 270-90 degrees, pink. Backward protrusions: 90-270 degrees,  
12 black. n = 425 protrusions from 11 cells in 5 embryos (DMSO), and 480 protrusions  
13 from 11 cells in 4 embryos (20 $\mu$ M LY). Fisher's exact test, P value < 0.0001. Error bars,  
14 mean  $\pm$  SEM. Scale bar, 30  $\mu$ m. Raw data and full p-values included in the source file.

15  
16  
17  
18

1 **Fig 5: Pdgfra activates and genetically interacts with PI3K signaling to regulate**  
2 **cardiac fusion. A, B** Immunoblot and ratiometric analysis of phosphorylated Akt (pAkt)  
3 compared to total Akt levels reveals reduced pAkt levels in loss-of-function *pdgfra*<sup>sk16</sup>  
4 heterozygous (-/+) or homozygous (-/-) mutant embryos at 22s (A), and elevated pAkt  
5 levels at 22s when PDGF signaling is activated with the *hs:pdgfaa* transgene (B). Bar  
6 graphs display averages from three separate experiments. **C-E** Dorsal views, anterior to  
7 the top, of the myocardium labeled with *myl7* at 22s. In contrast to a normal ring of  
8 myocardial cells in wild-type embryos treated with 10 $\mu$ M LY starting at bud stage (C) or  
9 *pdgfra* heterozygous embryos (D), when *pdgfra* heterozygous mutants are exposed to  
10 10 $\mu$ M LY, cardiac fusion is defective with embryos displaying severe phenotypes such  
11 as cardia bifida (E). **F** Bar graph depicts the average distribution of cardiac fusion  
12 defects in DMSO-treated wild-type and *pdgfra* heterozygous mutants as well as 10 $\mu$ M  
13 LY-treated wild-type and *pdgfra* heterozygous mutant embryos. The total number of  
14 embryos examined over three separate biological replicates are 47 (DMSO, +/+), 25  
15 (DMSO, -/+), 36 (10 $\mu$ M LY, +/+), and 31 (10 $\mu$ M LY, -/+). Blue - cardiac ring/normal;  
16 Orange - fusion only at posterior end/mild, Red - cardia bifida/severe. Bar graphs, mean  
17  $\pm$  SEM. One-way ANOVA (A, C) or Student's T-test (B), letter change indicates  $p <$   
18 0.05. Scale bar, 60 $\mu$ m. Raw data and full p-values included in the source file.

19

1 **Supplemental Fig. 1: The penetrance and severity of cardiac fusion defects in**  
2 **PI3K-inhibited embryos is dose-dependent. A-L** Dorsal views, anterior to the top, of  
3 the myocardium labeled with *myl7* at 22s. Incubation of embryos with LY (A-C), Dac (D-  
4 F), Pic (G-I) from bud stage to 22s or injection of embryos with *dnPI3K* mRNA (J-L) at  
5 the one-cell stage results in dose-dependent cardiac fusion defects at 22s. **M-P** Graphs  
6 depict the distribution of cardiac fusion defects in embryos treated with increasing  
7 concentrations of LY (M), Dac (N), Pic (O) or injected with increasing amounts of  
8 *dnPI3K* mRNA (P). Graphs reveal that both the percentage of embryos displaying  
9 cardiac fusion defects and the severity of those defects are dose-dependent. Total  
10 number of embryos analyzed (n) from > 3 treatments or injections at the indicated  
11 concentrations in (M-P): LY- 40, 40, 30, 31, 31; Dac: 38, 34, 39; Pic: 37, 39, 38, *dnPI3K*  
12 mRNA: 73, 52, 61, 57, 52, respectively. Dots indicate the percent of embryos displaying  
13 a specific phenotype per incubation. Blue - Cardiac ring/normal; Orange - fusion only at  
14 posterior end/mild, Red - cardia bifida/severe. Bar graphs, mean  $\pm$  SEM. One-Way  
15 ANOVA comparing percent of cardiac fusion defects- letter change indicates  $p < 0.05$ .  
16 Scale = 60  $\mu$ m. Full p-values included in the source file.

17

1 **Supplemental Fig. 2: LY-incubation results in trunk extension and somite**  
2 **formation delays. A-B, D-E** Lateral brightfield views of 20 hours post fertilization (hpf)  
3 embryos treated with DMSO (A, D) or 20 $\mu$ M LY (B, E) at bud stage. **C, F** Box-whisker  
4 plot depicting the average embryonic length (yellow curved line in A, B) or somite  
5 number (yellow dots in D, E) at 20 hpf. Total number of embryos (n) from > 3 separate  
6 incubations = 40 (DMSO), 40 (20 $\mu$ M LY) for (C), and 39 (DMSO), 42 (20 $\mu$ M LY) for (F).  
7 Dots = measurements from individual embryos. Two sample t-test; p-value =  $4.527 \times 10^{-4}$   
8 and  $7.624 \times 10^{-5}$ , respectively. **G-H** Dorsal views, anterior to the top, of the myocardium  
9 labeled with *myl7* at 20 hpf. Embryos treated with DMSO at bud stage show cardiac  
10 rings (G) whereas those treated with 20 $\mu$ M LY show cardia bifida at 20 hpf (H). **I** Graph  
11 depicts the average percentage of cardiac fusion defects in embryos treated with DMSO  
12 or 20 $\mu$ M LY. The total number of embryos examined from three separate incubations (n)  
13 = 45 (DMSO), 45 (20 $\mu$ M LY). Two sample t-test; p-value =  $4.56 \times 10^{-5}$ . Dots indicate the  
14 percent of embryos with cardiac fusion defects per incubation. Letter changes (C, F, I)  
15 indicate p-values < 0.05. Raw data and full p-values included in the source file.

21

1 **Supplemental Fig 3: The morphologies of the myocardium and anterior endoderm**  
2 **are not compromised in PI3K-inhibited embryos. A-F** Representative transverse  
3 cryosections, dorsal to the top, compare the morphology of the myocardium, visualized  
4 with *Tg(myl7:eGFP)* (green), ZO1 (purple) and DAPI (blue) between DMSO- (A-C) and  
5 20 $\mu$ M LY- (D-F) treated (bud-20s) embryos. Box (A, D) indicate region magnified in B,  
6 C, E, F. **G-I** Representative 3D confocal images of the myocardium at 20s, which were  
7 used to count myocardial cells in DMSO- (G) or 20 $\mu$ M LY - (H) treated embryos. Yellow  
8 dots indicate individual myocardial cells counted using ImageJ. Graph depicts box-  
9 whisker plots for the average number of myocardial cells. 21 (DMSO) and 25 (LY)  
10 embryos from 4 separate bud-20s incubations were analyzed (I). **J-Q** Dorsal views,  
11 anterior to the top, of the anterior endoderm labeled with *axial* (J-L) or the  
12 *Tg(sox17:eGFP)* transgene (N-P) at 30s. Embryos incubated with either DMSO (J, N) or  
13 15 $\mu$ M LY (K, O) or 25 $\mu$ M LY (L, P) from the bud stage to 30s show no observable  
14 difference in the appearance or width of the anterior endoderm. Box-whisker plots of the  
15 average width of the anterior endoderm labeled with either *axial* (M) or *Tg(sox17:eGFP)*  
16 (Q). 47 (*axial*) and 42 (*Tg(sox17:egfp)*) embryos per inhibitor concentration from three  
17 separate incubations were analyzed. Yellow lines: width of the endodermal sheet.  
18 Purple dots (I, M, Q) indicate individual embryos. Letter differences indicate a p-value <  
19 0.05 as tested by 1-way ANOVA. Scale bars, 10 (A-F), 42 (G-H), 60 (J-L), and 50 (N-P)  
20  $\mu$ m. Raw data and full p-values included in the source file.

1  
2 **Supplemental Fig. 4: Myocardial movement towards the midline is disrupted in**  
3 **PI3K-inhibited embryos throughout cardiac fusion. A-H** Dorsal views, anterior to the  
4 top, of embryos displaying the expression of *hand2* in the anterior lateral plate  
5 mesoderm (ALPM) at (A, E) 12s, (B, F) 14s, (C, G) 18s and (D, H) 20s, treated with  
6 either DMSO (A-D) or 20 $\mu$ M LY (E-H) at bud stage. **I** Box-whisker plots depict the  
7 average distance between the sides of the ALPM. Although, *hand2* is properly  
8 expressed in LY-exposed embryos, ALPM convergence is affected as early as the 10s  
9 stage, with a dramatic difference in convergence starting at 12s. The total number of  
10 embryos analyzed (n), from 3 separate incubations at the noted stages (I) are: n = 34,  
11 33, 31, 32, 34, 34 (DMSO); 32, 29, 30, 34, 31, 28 (20 $\mu$ M LY), respectively. Dots indicate  
12 the distance between ALPM sides per embryo. Student's t-test: asterisk indicates p  
13 values < 0.05. Scale bar, 100 $\mu$ m. Raw data and full p-values included in the source file.  
14  
15  
16

1 **Supplemental Fig. 5. PI3K signaling directs myocardial movement during the**  
2 **early stages of cardiac fusion and regulates velocity throughout cardiac fusion.**

3 **A-B** Time-lapse confocal reconstructions from Figure 3 overlaid with cell movement  
4 tracks, starting at  $t = 0$  (yellow dots). Scale bar,  $60\mu\text{m}$ . **C, D** Box-whisker plots display  
5 the average velocity (C) and direction of movement (D) sub-divided at three distinct  
6 stages of cardiac fusion: early movement (0 - 48min), posterior fusion (49 - 99min) and  
7 anterior fusion (100 - 153min). The average velocity of myocardial cells in LY-treated  
8 embryos is consistently slower than the velocity of DMSO-treated embryos which is  
9 consistent throughout cardiac fusion (C). However, in LY-treated embryos myocardial  
10 cells display a more angular average direction of movement compared to DMSO-treated  
11 embryos during the early stages of cardiac fusion (Early movement, Posterior fusion),  
12 after which wild-type myocardial cell movement becomes more angular matching  
13 myocardial cell movements in LY-treated embryos. Two sample t-test, letter change  
14 indicates  $p < 0.05$ .

15  
16

1 **Video 1. Myocardial cells in DMSO-treated embryos collectively move towards the**  
2 **midline and form a ring during cardiac fusion. A-C** Representative time-lapse movie  
3 of myocardial cells visualized with *Tg(myI7:egfp)* during cardiac fusion in a DMSO-  
4 treated embryo (A), tracks show movement of selected cells from the timelapse video  
5 (B) and overlay of eGFP and tracks (C). Time-lapse images are of three-dimensional  
6 reconstruction of confocal slices taken at 4:32 min intervals for 2.5 hours, beginning at  
7 14s.  
8

1 **Video 2. Myocardial cells in PI3K-inhibited embryos fail to move properly towards**  
2 **the midline. A-C** Representative time-lapse movie of myocardial cells visualized with  
3 *Tg(myl7:egfp)* (A), tracks of selected cells (B), and overlay of tracks and eGFP (C) from  
4 an embryo treated with 20 $\mu$ M LY from bud-20s. Time-lapse was acquired as described  
5 in Video 1.  
6  
7

1 **Video 3. PI3K signaling promotes the medial directional movement of myocardial**  
2 **cells towards the midline. A, B** Side-by-side comparison of myocardial movement in  
3 DMSO- (A, video 1) and LY- (B, video 2) treated embryos reveals that inhibition of PI3K  
4 signaling by LY prevents myocardial cells from being adequately directed towards the  
5 midline. Selected analyzed tracks (white lines) overlaying 3D reconstructions of the  
6 *Tg(myf7:egfp)* transgene (green) in DMSO (A) and 20 $\mu$ M LY (B) treated embryos.  
7  
8

1 **Video 4. Dynamic medially oriented myocardial membrane protrusions are**  
2 **lacking in PI3K-inhibited embryos.** Representative time-lapse movies of myocardial  
3 membrane protrusions during cardiac fusion, visualized by injecting *myl7:lck-eGFP*  
4 plasmids at the 1-cell stage, in DMSO- (left panel) or 20 $\mu$ M LY – (right panel) treated  
5 embryos. **Left panel** highlights membrane protrusions (red arrowheads) in a set of  
6 posterior myocardial cells in a DMSO-treated embryo. Myocardial membrane  
7 protrusions in DMSO-treated embryos are mostly directed in the medial orientation  
8 (towards the right in both panels). **Right panel** highlights myocardial membrane  
9 protrusions (red arrowheads) in PI3K-inhibited embryos during cardiac fusion. Medial  
10 membrane protrusions (towards the right) are lacking in PI3K-inhibited embryos. DMSO  
11 or LY treatment from bud-20s. Time-lapse movies are 3D reconstruction of confocal  
12 images of membrane protrusions taken at  $\sim$ 90s intervals for 2 hours. Scale bar, 10 $\mu$ m.  
13  
14  
15

1 **Supplemental Table S1. Primers for genotyping and cloning.**

2

	<b>Name</b>	<b>Sequence (5'-3')</b>
Primers to screen for the <i>Tg(myl7:dnPI3K)</i> transgene in F1 embryos	dnPI3K_F1	GCGGGAAGAGGACATTGACT
	dnPI3K_R1	GCGGGAAGAGGACATTGACT
Primers to clone lck-emGFP into the middle-entry vector of the tol2 gateway system	Hifi_lck_1F	CAGTCGACTGGATCCGGTACAGATCCGCTAGCCACCATG
	Hifi_lck_1R	CAGTCGACTGGATCCGGTACAGATCCGCTAGCCACCATG
	Hifi_emgfp_2F	GGTCGCCACCGTGTCCAAGGGCGAGGAG
	Hifi_emgfp_2R	GGTCGCCACCGTGTCCAAGGGCGAGGAG

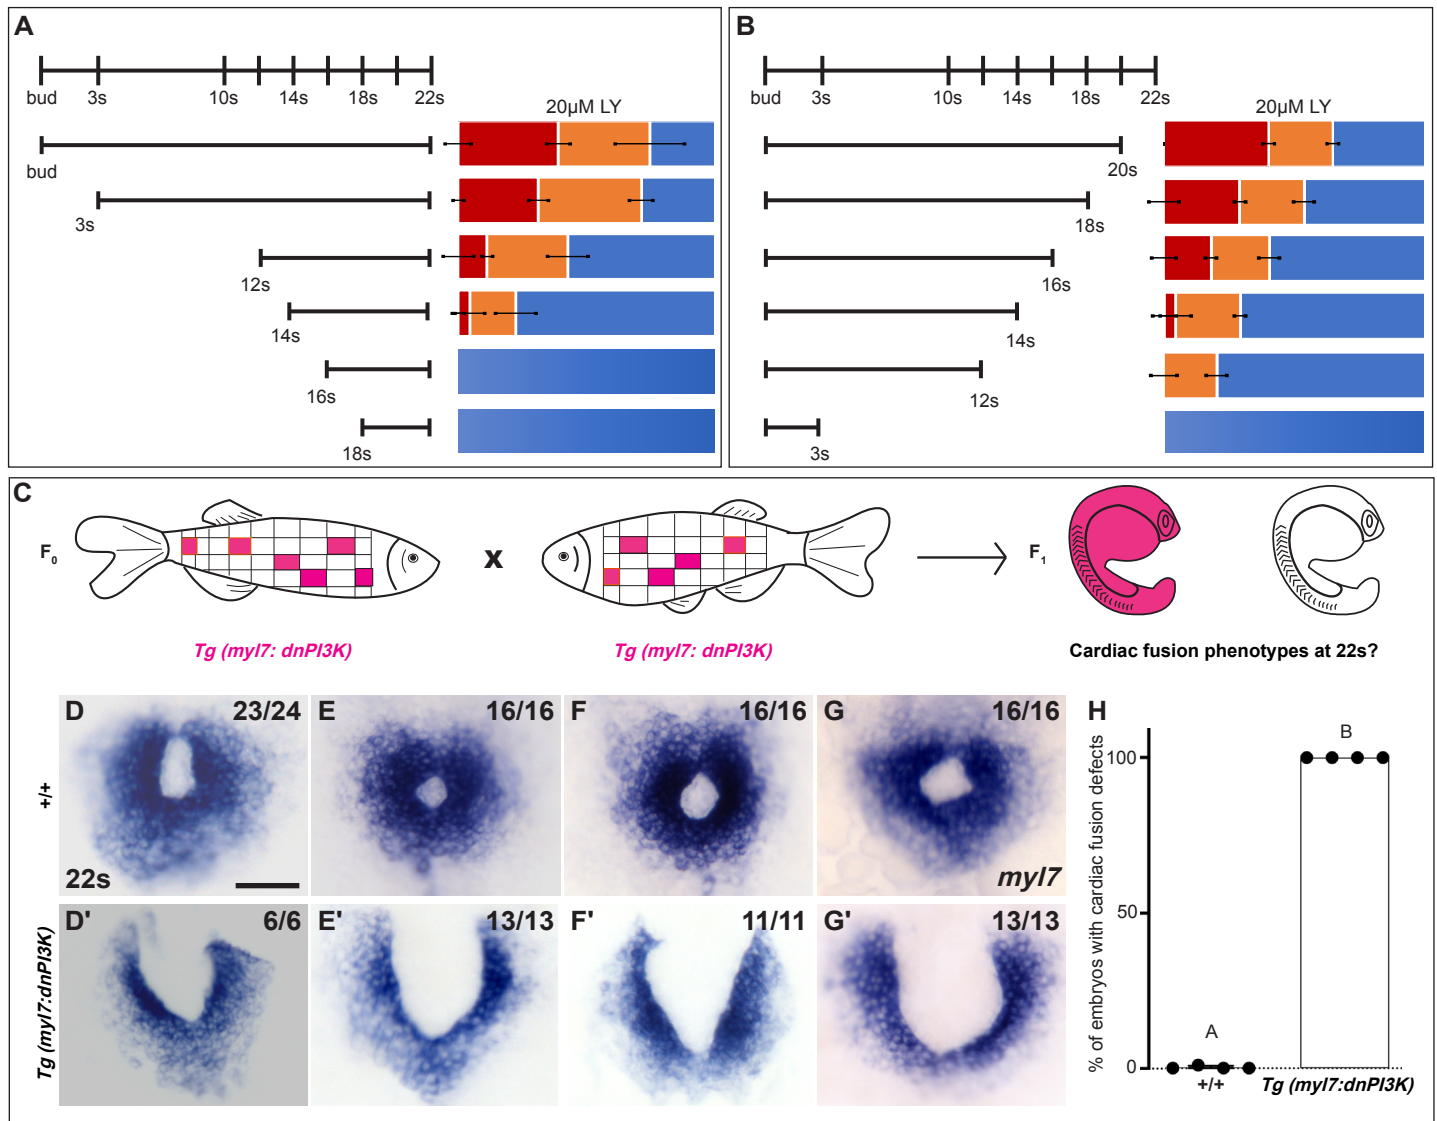

## Figure 1

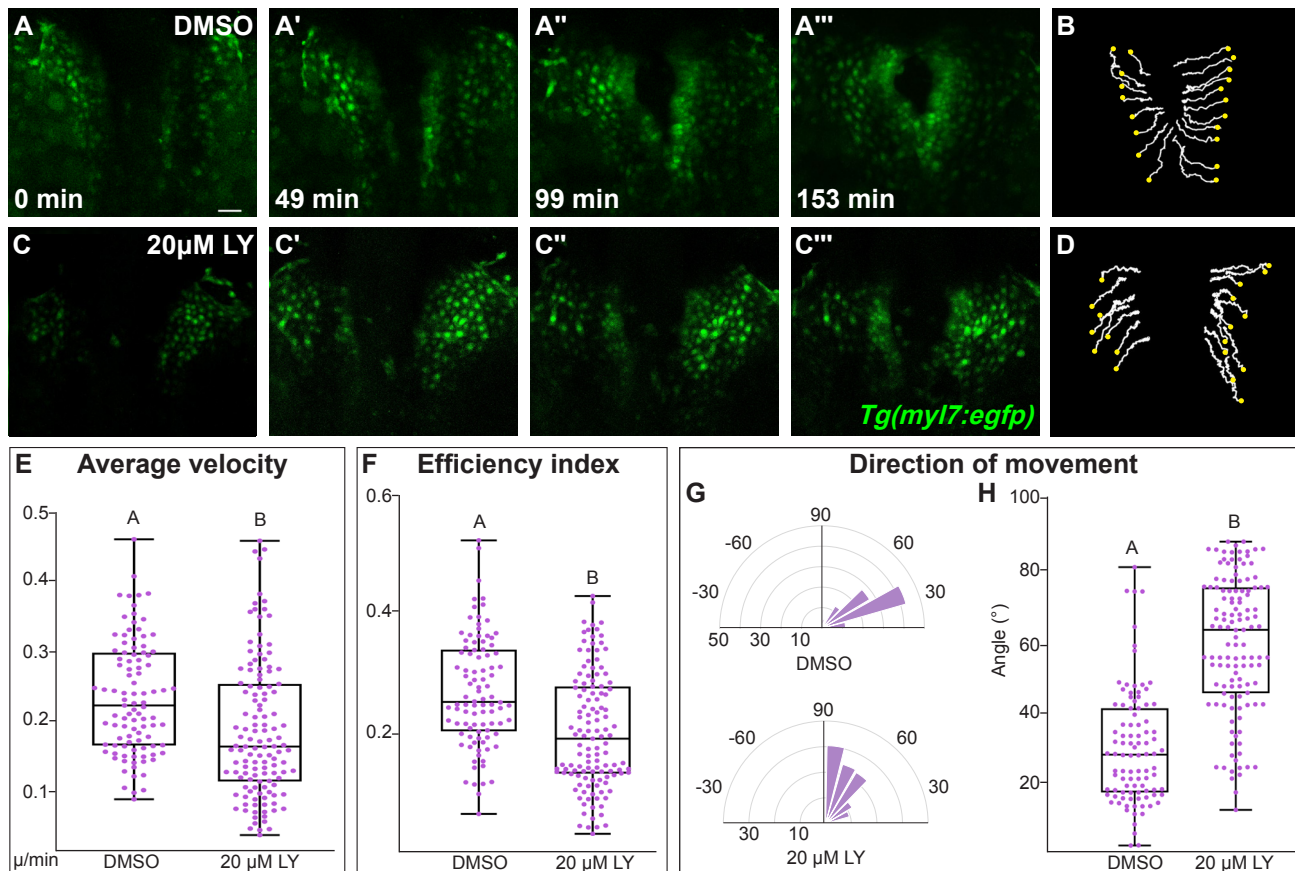

**Fig. 1. The PI3K pathway is required for cardiac fusion.** **A-E** Dorsal views, anterior to the top, of the myocardium labeled with *myl7* (A-E) at 22 somite stage (s) or *Tg(myl7:egfp)* (A'-E') at 20s. In contrast to a ring of myocardial cells in DMSO-treated embryos (A, A'), in embryos treated with PI3K inhibitors LY294002 (LY, B, B'), Dactolisib (Dac, C, C'), or Pictilisib (Pic, D, D') at bud stage or injected with *dnPI3K* mRNA (750pg) at the one-cell stage (E, E') cardiac fusion fails to occur properly with embryos displaying either cardia bifida (B, C) or fusion only at the posterior end (D, E). **F, G** Graphs depict the percentage (F) and range (G) of cardiac fusion defects in control and PI3K-inhibited embryos. Dots represent the percent of embryos with cardiac defects per biological replicate. Total embryos analyzed n = 37 (DMSO), 31 (20 $\mu$ M LY), 39 (40 $\mu$ M Dac), 38 (50 $\mu$ M Pic), 86 (*dnPI3K*). Blue - cardiac ring/normal; Orange - fusion only at posterior end/mild phenotype, Red - cardia bifida/severe phenotype. **H** Representative immunoblot and ratiometric analysis of phosphorylated Akt (pAkt) to Akt protein levels in DMSO and LY treated embryos reveals a dose-dependent decrease in PI3K activation. Bar graphs indicate mean  $\pm$  SEM, dots indicate pAKT/AKT ratio per biological replicate, normalized to DMSO. Three biological replicates per treatment. One-Way ANOVA tests - letter changes indicate differences of  $p < 0.05$  (F, H). Scale bars, 40  $\mu$ m (A-E), 42  $\mu$ m (A'-E'). Raw data and full p-values included in the source file.

**Figure 2**

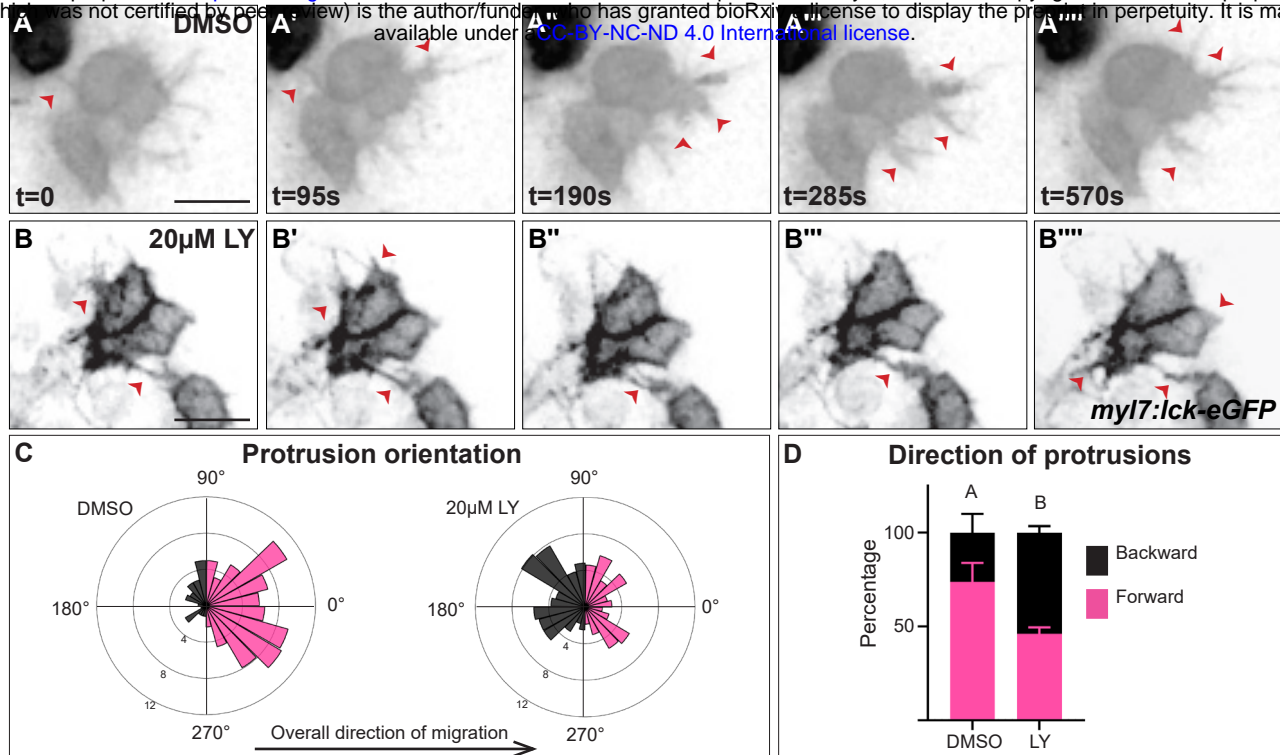

**Fig 2: PI3K is required in the myocardium throughout cardiac fusion. A, B** Graphical representation of the PI3K inhibitor addition (A) and wash-out (B) experiments used to determine the developmental stage over which PI3K is required. In (A) LY is added to embryos at different developmental stages and incubated until 22s, when cardiac fusion is assessed. In (B) LY is added at bud stage and washed-out at different developmental stages after which embryos are incubated in normal media till 22s when cardiac fusion is assessed. Bar graphs indicate the average proportion of embryos displaying different phenotypes. Blue - cardiac ring/normal; Orange - fusion only at posterior end/mild phenotype, Red - cardia bifida/severe phenotype. n = 45 embryos per treatment condition from 3 biological replicates. **C** Schematic outlines experimental design to test requirement for PI3K in the myocardium. Pink – cells with the *Tg(myl7:dnPI3K)* transgene. F0 animals are mosaic for the transgene, while all cells in F1 embryos either have the transgene (pink) or do not (clear). The *myl7* promoter restricts *dnPI3K* expression to the myocardium in *Tg(myl7:dnPI3K)* embryos. **D-G** Dorsal view, anterior to the top, of the myocardium labeled with *myl7* in embryos at 22s from 4 different founder pairs (D-D', E-E', F-F', G-G'). F1 embryos without the *Tg(myl7:dnPI3K)* transgene (as determined by genotyping) display normal cardiac fusion (D-G, n = 23/24, 16/16, 16/16, 16/16, per founder pair), while F1 siblings with the *Tg(myl7:dnPI3K)* transgene display cardiac fusion defects (D'-G', n = 6/6, 13/13, 11/11, 13/13), indicating PI3K signaling is required in the myocardium. **H** Graph indicating the average % of wild-type and *Tg(myl7:dnPI3K)*+ embryos with cardiac fusion defects. Letter difference indicates a significant Fisher's exact test  $p = 5.56 \times 10^{-31}$ . Scale bar, 40 $\mu$ m.

**Figure 3**

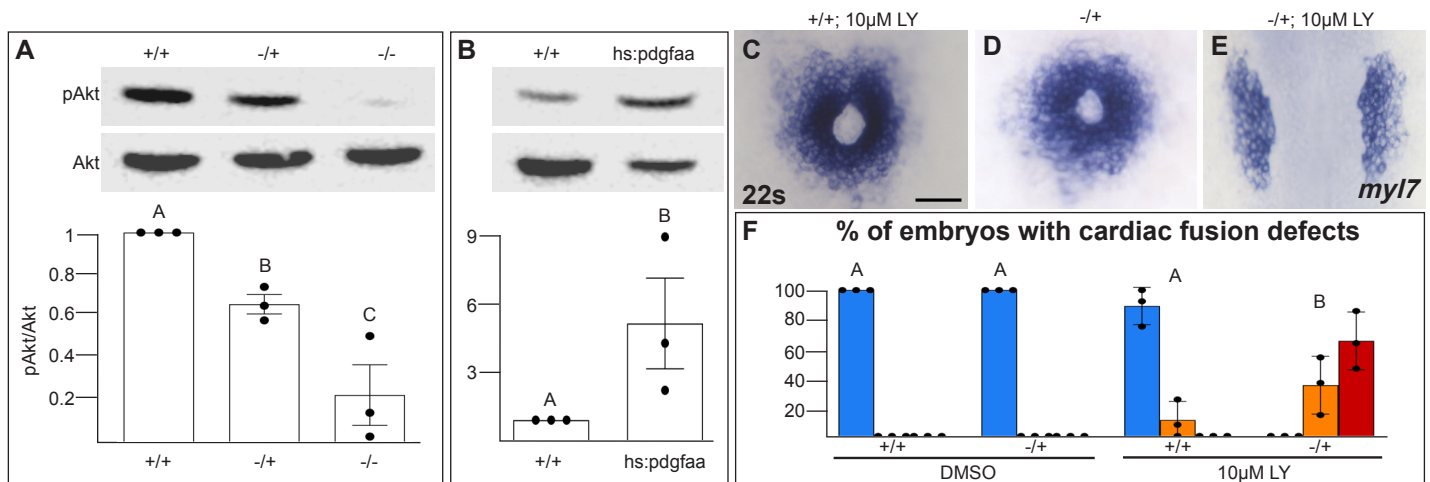

**Fig 3: PI3K signaling regulates the medial movement and velocity of the myocardium during cardiac fusion.** A-D Time points from a representative time-lapse video of myocardial cells visualized with the *Tg(myl7:egfp)* transgene in embryos treated with DMSO (A, B, Video-1) or 20µM LY (C, D, Video-2) from bud - 22s. 3D reconstructions of confocal slices (A, C) reveal the changes in conformation and location of the myocardium at 3 major stages of cardiac fusion: early medial movement towards the embryonic midline (A-A', C-C'), posterior merging of bilateral populations (A'', C'') and anterior merging to form a ring (A''', C'''). Representative tracks (B, D) show the paths of a subset of myocardial cells over ~2.5 hr timelapse. Yellow dots indicate the starting point of each track. E-H Graphs depict box-whisker plots of the velocity (E), efficiency index (F) and angle of movement (H) of myocardial cells. The direction of movement is visualized by rose plots (G). Myocardial cells in PI3K-inhibited (LY-treated) embryos show an overall direction of movement that is angular (60-90 degrees) and is slower than in DMSO-treated embryos. 96 and 125 cells were analyzed from five DMSO- and six 20µM LY- treated embryos respectively. Two sample t-test, letter change indicates p < 0.05. Scale bars, 60 µm. Raw data and full p-values included in the source file.

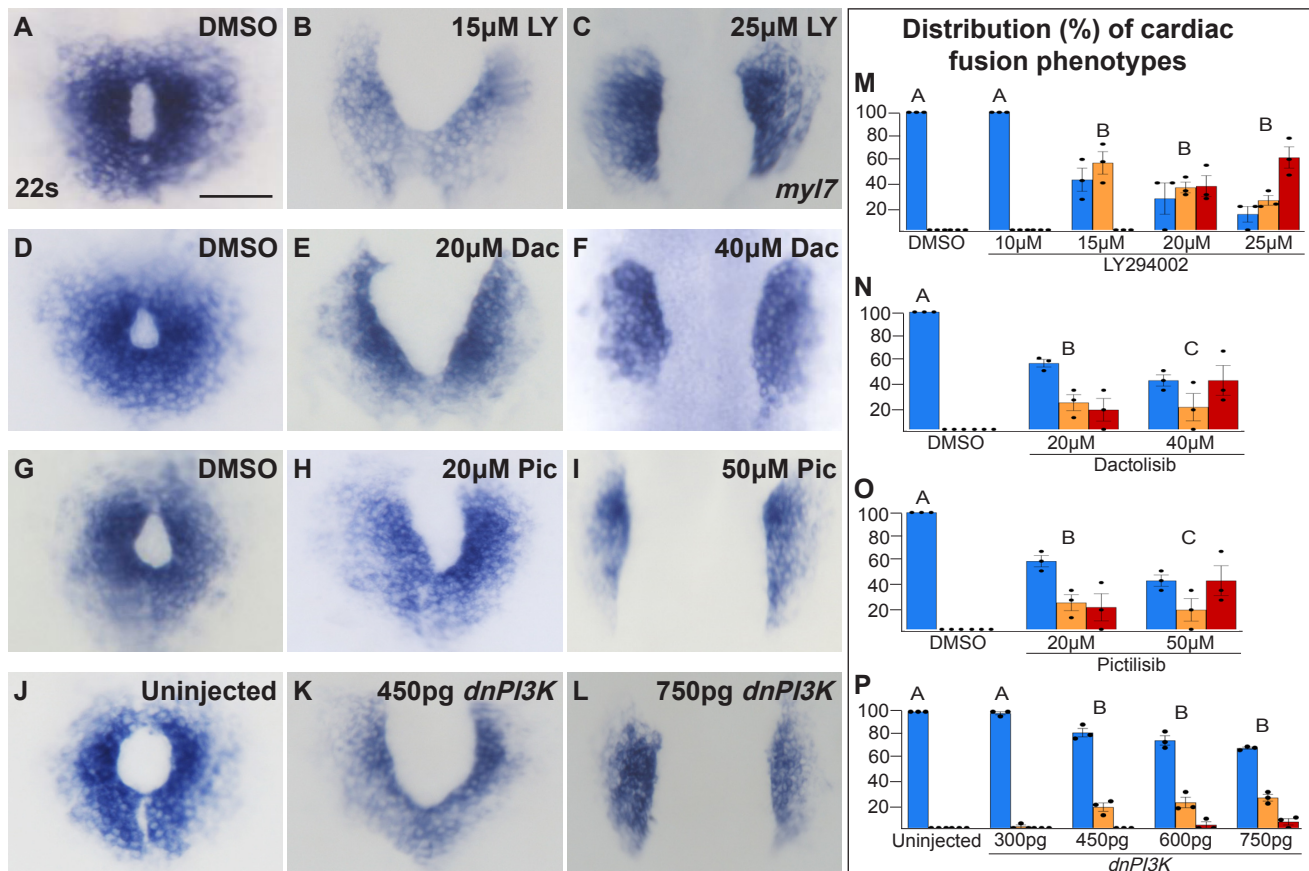

**Fig 4: Myocardial membrane protrusions are misdirected in PI3K-inhibited embryos.** **A-B''''** timepoints from a representative timelapse video (see Video-4) of myocardial cells whose membrane has been labeled with *myl7:lck-eGFP* (black), medial to the right, in a DMSO- (A-A''') or a 20 µM LY- (B-B''') treated embryo. Red arrowheads indicate representative protrusions, which are oriented medially coincident with the direction of movement in DMSO-treated embryos (A-A''') but are oriented in all directions in LY-treated embryos (B-B'''). **C, D** Rose (C) and bar (D) graphs displaying the orientation of membrane protrusions in DMSO- (left) or LY- (right) treated embryos. The length of each radial bar in (C) represents the percentage of protrusions in each bin. Bar graph displays the total percentage of forward or backward protrusions. Forward protrusions: 270-90 degrees, pink. Backward protrusions: 90-270 degrees, black.  $n = 425$  protrusions from 11 cells in 5 embryos (DMSO), and 480 protrusions from 11 cells in 4 embryos (20µM LY). Fisher's exact test,  $P$  value  $< 0.0001$ . Error bars, mean  $\pm$  SEM. Scale bar, 30 µm. Raw data and full  $p$ -values included in the source file.

**Figure 5**

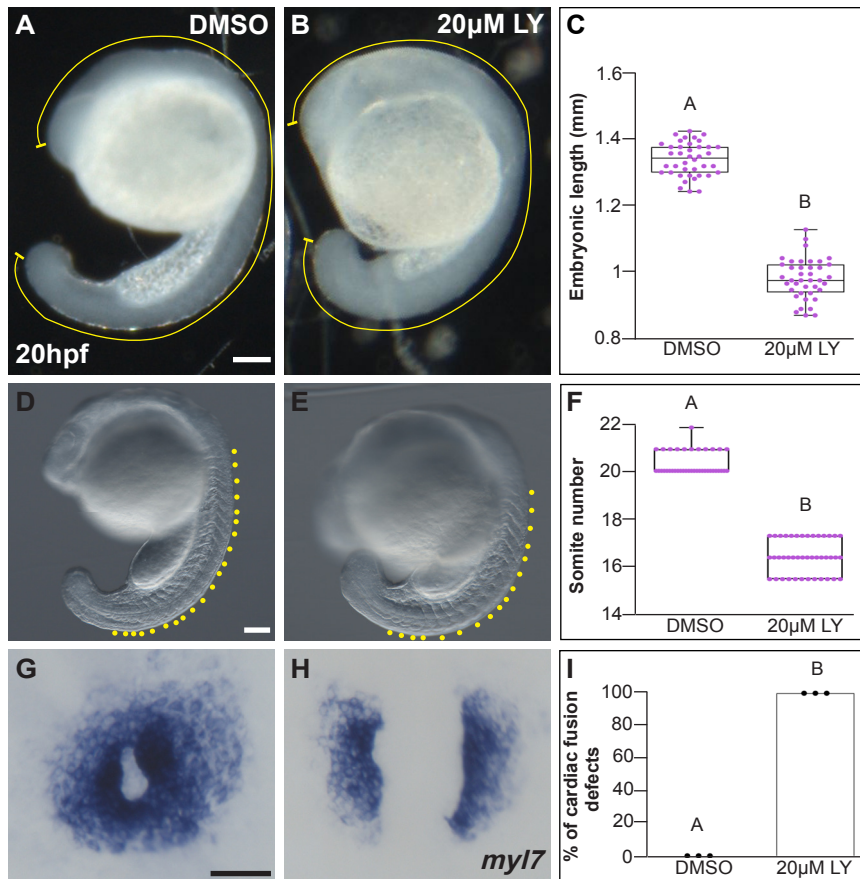

**Fig 5: Pdgfra activates and genetically interacts with PI3K signaling to regulate cardiac fusion.** **A, B** Immunoblot and ratiometric analysis of phosphorylated Akt (pAkt) compared to total Akt levels reveals reduced pAkt levels in loss-of-function *pdgfra*<sup>sk16</sup> heterozygous (-/+) or homozygous (-/-) mutant embryos at 22s (A), and elevated pAkt levels at 22s when PDGF signaling is activated with the *hs:pdgfaa* transgene (B). Bar graphs display averages from three separate experiments. **C-E** Dorsal views, anterior to the top, of the myocardium labeled with *myl7* at 22s. In contrast to a normal ring of myocardial cells in wild-type embryos treated with 10µM LY starting at bud stage (C) or *pdgfra* heterozygous embryos (D), when *pdgfra* heterozygous mutants are exposed to 10µM LY, cardiac fusion is defective with embryos displaying severe phenotypes such as cardia bifida (E). **F** Bar graph depicts the average distribution of cardiac fusion defects in DMSO-treated wild-type and *pdgfra* heterozygous mutants as well as 10µM LY-treated wild-type and *pdgfra* heterozygous mutant embryos. The total number of embryos examined over three separate replicates are 47 (DMSO, +/+), 25 (DMSO, -/+), 36 (10µM LY, +/+), and 31 (10µM LY, -/+). Blue - cardiac ring/normal; Orange - fusion only at posterior end/mild, Red - cardia bifida/severe. Bar graphs, mean ± SEM. One-way ANOVA (A, C) or Student's T-test (B), letter change indicates p < 0.05. Scale bar, 60µm. Raw data and full p-values included in the source file.

## Suppl. Figure 1

**Supplemental Fig. 1: The penetrance and severity of cardiac fusion defects in PI3K-inhibited embryos is dose-dependent.** A-L Dorsal views, anterior to the top, of the myocardium labeled with *myl7* at 22s. Incubation of embryos with LY (A-C), Dac (D-F), Pic (G-I) from bud stage to 22s or injection of embryos with *dnPI3K* mRNA (J-L) at the one-cell stage results in dose-dependent cardiac fusion defects at 22s. M-P Graphs depict the distribution of cardiac fusion defects in embryos treated with increasing concentrations of LY (M), Dac (N), Pic (O) or injected with increasing amounts of *dnPI3K* mRNA (P). Graphs reveal that both the percentage of embryos displaying cardiac fusion defects and the severity of those defects are dose-dependent. Total number of embryos analyzed (n) from > 3 treatments or injections at the indicated concentrations in (M-P): LY- 40, 40, 30, 31, 31; Dac: 38, 34, 39; Pic: 37, 39, 38, *dnPI3K* mRNA: 73, 52, 61, 57, 52, respectively. Dots indicate the percent of embryos displaying a specific phenotype per incubation. Blue - Cardiac ring/normal; Orange - fusion only at posterior end/mild, Red - cardia bifida/severe. Bar graphs, mean  $\pm$  SEM. One-Way ANOVA comparing percent of cardiac fusion defects-letter change indicates  $p < 0.05$ . Scale = 60  $\mu$ m. Data with full p-values included in the source file.

## Suppl. Figure 2

**Supplemental Fig. 2: LY-incubation results in trunk extension and somite formation delays.** **A-B, D-E** Lateral brightfield views of 20 hours post fertilization (hpf) embryos treated with DMSO (**A, D**) or 20µM LY (**B, E**) at bud stage. **C, F** Box-whisker plot depicting the average embryonic length (yellow curved line in **A, B**) or somite number (yellow dots in **D, E**) at 20 hpf. Total number of embryos (n) from >3 separate incubations = 40 (DMSO), 40 (20µM LY) for (**C**), and 39 (DMSO), 42 (20µM LY) for (**F**). Dots = measurements from individual embryos. Two sample t-test; p-value =  $4.527 \times 10^{-4}$  and  $7.624 \times 10^{-5}$ , respectively. **G-H** Dorsal views, anterior to the top, of the myocardium labeled with *myl7* at 20 hpf. Embryos treated with DMSO at bud stage show cardiac rings (**G**) whereas those treated with 20µM LY show cardia bifida at 20 hpf (**H**). **I** Graph depicts the average percentage of cardiac fusion defects in embryos treated with DMSO or 20µM LY. The total number of embryos examined over three separate incubations (n) = 45 (DMSO), 45 (20µM LY). Two sample t-test; p-value =  $4.56 \times 10^{-5}$ . Dots indicate the percent of embryos with cardiac fusion defects per incubation. Letter changes (**C, F, I**) indicate p-values < 0.05. Raw data and full p-values included in the source file.

Suppl. Figure 3

**Supplemental Fig 3: The morphologies of the myocardium and anterior endoderm are not compromised in PI3K-inhibited embryos.** **A-F** Representative transverse cryosections, dorsal to the top, compare the morphology of the myocardium, visualized with *Tg(my17:eGFP)* (green), ZO1 (purple) and DAPI (blue) between DMSO- (**A-C**) and 20µM LY- (**D-F**) treated (bud-20s) embryos. Box (**A**, **D**) indicate region magnified in **B**, **C**, **E**, **F**. **G-I** Representative 3D confocal images of the myocardium at 20s, which were used to count myocardial cells in DMSO- (**G**) or 20µM LY - (**H**) treated embryos. Yellow dots indicate individual myocardial cells counted using ImageJ. Box-whisker plots depict the average number of myocardial cells. 21 (DMSO) and 25 (LY) embryos from 4 separate bud-20s incubations were analyzed (**I**). **J-Q** Dorsal views, anterior to the top, of the anterior endoderm labeled with *axial* (**J-L**) or the *Tg(sox17:eGFP)* transgene (**N-P**) at 30s. Embryos incubated with either DMSO (**J**, **N**) or 15µM LY (**K**, **O**) or 25µM LY (**L**, **P**) from the bud stage to 30s show no observable difference in the appearance or width of the anterior endoderm. Box-whisker plots of the average width of the anterior endoderm labeled with either *axial* (**M**) or *Tg(sox17:eGFP)* (**Q**). 47 (*axial*) and 42 (*Tg(sox17:egfp)*) embryos per inhibitor concentration from three separate incubations were analyzed. Yellow lines: width of the endodermal sheet. Purple dots (**I**, **M**, **Q**) indicate individual embryos. Letter differences indicate a p-value < 0.05 as tested by 1-way ANOVA. Scale bars, 10 (**A-F**), 42 (**G-H**), 60 (**J-L**), and 50 (**N-P**) µm. Raw data and full p-values included in the source file.

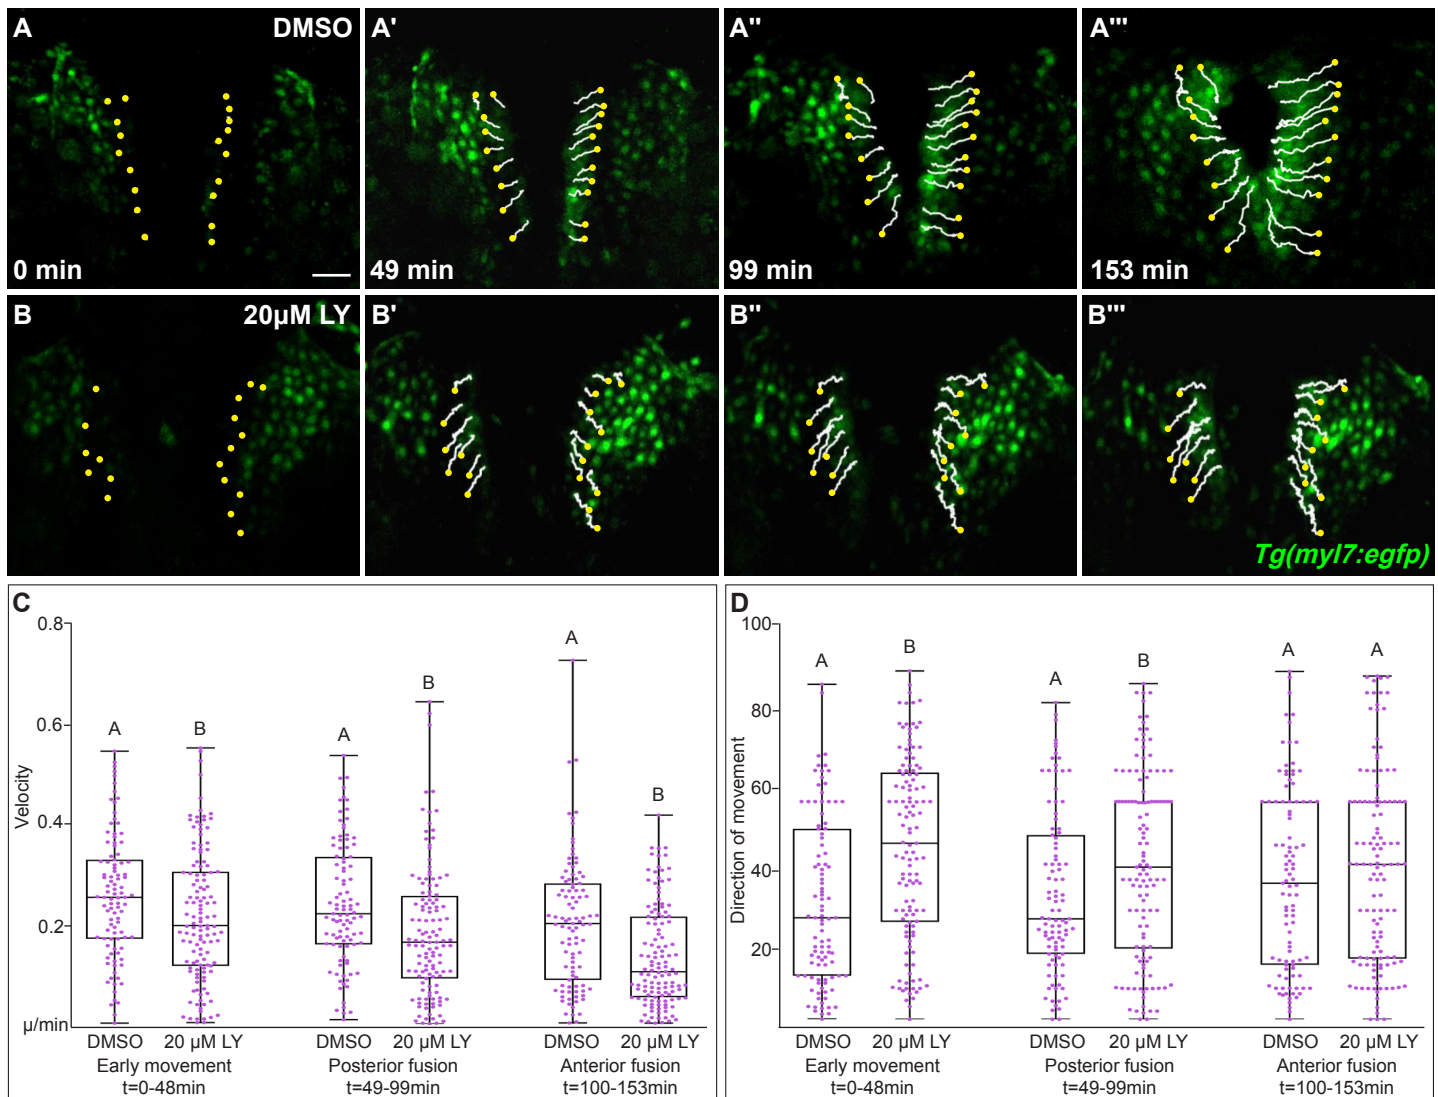

## Suppl. Figure 4

**Supplemental Fig. 4: Myocardial movement towards the midline is disrupted in PI3K-inhibited embryos throughout cardiac fusion.** A-H Dorsal views, anterior to the top, of embryos displaying the expression of *hand2* in the anterior lateral plate mesoderm (ALPM) at (A, E) 12s, (B, F) 14s, (C, G) 18s and (D, H) 20s, treated with either DMSO (A-D) or 20µM LY (E-H) at bud stage. I Box-whisker plots depict the average distance between the sides of the ALPM. Although, *hand2* is properly expressed in LY-exposed embryos, ALPM convergence is affected as early as the 10s stage, with a dramatic difference in convergence starting at 12s. The total number of embryos analyzed (n), from 3 separate incubations at the noted stages (I) are: n = 34, 33, 31, 32, 34, 34 (DMSO); 32, 29, 30, 34, 31, 28 (20µM LY), respectively. Dots indicate the distance between ALPM sides per embryo. Student's t-test: asterisk indicates p values < 0.05. Scale bar, 100µm. Raw data and full p-values included in the source file.

Suppl. Figure 5

**Supplemental Fig. 5. PI3K signaling directs myocardial movement during the early stages of cardiac fusion and regulates velocity throughout cardiac fusion. A-B** Time-lapse confocal reconstructions from Figure 3 overlaid with cell movement tracks, starting at t = 0 (yellow dots). Scale bar, 60 $\mu$ m. **C, D** Box-whisker plots display the average velocity (C) and direction of movement (D) sub-divided at three distinct stages of cardiac fusion: early movement (0 - 48min), posterior fusion (49 - 99min) and anterior fusion (100 - 153min). The average velocity of myocardial cells in LY-treated embryos is consistently slower than the velocity of DMSO-treated embryos which is consistent throughout cardiac fusion (C). However, in LY-treated embryos myocardial cells display a more angular average direction of movement compared to DMSO-treated embryos during the early stages of cardiac fusion (Early movement, Posterior fusion), after which wild-type myocardial cell movement becomes more angular matching myocardial cell movements in LY-treated embryos. Two sample t-test, letter change indicates p < 0.05. Raw data and full p-values included in the source file.
