Abstract:	Introduction The study was conducted to evaluate the effects of visualization-based training on lung auscultation during clinical clerkship (CC) in the department of Respiratory Medicine on student skills and confidence. Methods The study period was December 2020 to November 2021. In total, 79 students attended a lecture on lung auscultation featuring a simulator (Mr. Lung™). Out of these attendees, 35 students (visualization group) received additional training wherein they were asked to mentally visualize lung sounds using a diagram of graphical visualized lung sounds as an example. All students answered questions on their self-efficacy regarding lung auscultation before and after four weeks of CC. They also took a lung auscultation test with the simulator at the beginning of CC (pre-test) and on the last day of the third week (post-test) (maximum score: 25). We compared the answers in the questionnaire and the test scores between the visualization group and students who only attended the lecture (control group, n=30). Results Confidence in auscultation of lung sounds significantly increased in both groups (five-point Likert scale, visualization group: pre 1.5 ± 0.1 to post 3.2 ± 0.1, p<0.001; control group: 1.7 ± 0.1 to 2.9 ± 0.1, p<0.001), and was significantly higher in the visualization group than in the control group. Moreover, test scores increased in both groups (visualization group: pre-test 11.4 ± 0.5 to post-test 15.1 ± 0.6, p<0.001; control group: 11.1 ± 0.5 to 14.3 ± 0.6, p<0.001). Although there were no differences between the pre- and post-tests scores of both groups, the score of the visualization group tended to increase compared with that of the control group (p=0.623). Conclusion Visualizing lung sounds may increase medical students' confidence in their lung auscultation skills; notably, this may reduce their resistance to lung auscultation and encourage the repeated auscultation necessary to further improve their long-term auscultation abilities over the long term.

Abstract

Introduction: The study was conducted to evaluate the effects of visualization-based training on lung auscultation during clinical clerkship (CC) in the department of Respiratory Medicine on student skills and confidence.

Methods: The study period was December 2020 to November 2021. In total, 79 students attended a lecture on lung auscultation featuring a simulator (Mr. Lung™). Out of these attendees, 35 students (visualization group) received additional training wherein they were asked to mentally visualize lung sounds using a diagram of graphical visualized lung sounds as an example. All students answered questions on their self-efficacy regarding lung auscultation before and after four weeks of CC. They also took a lung auscultation test with the simulator at the beginning of CC (pre-test) and on the last day of the third week (post-test) (maximum score: 25). We compared the answers in the questionnaire and the test scores between the visualization group and students who only attended the lecture (control group, n=30).

Results: Confidence in auscultation of lung sounds significantly increased in both groups (five-point Likert scale, visualization group: pre 1.5 ± 0.1 to post 3.2 ± 0.1, $p<0.001$; control group: 1.7 ± 0.1 to 2.9 ± 0.1, $p<0.001$), and was significantly higher in the visualization group than in the control group. Moreover, test scores increased in both groups (visualization group: pre-test 11.4 ± 0.5 to post-test 15.1 ± 0.6, $p<0.001$; control group: 11.1 ± 0.5 to 14.3 ± 0.6, $p<0.001$). Although there were no differences between the pre- and post-tests scores of both groups, the score of the visualization group tended to increase compared with that of the control group ($p=0.623$).

Conclusion: Visualizing lung sounds may increase medical students' confidence in their lung auscultation skills; notably, this may reduce their resistance to lung auscultation and encourage the repeated auscultation necessary to further improve their long-term auscultation abilities over the long term.

Introduction

Lung auscultation is a fundamental part of physical examination; it is routinely performed by doctors and other medical professionals alike. Lung auscultation is a useful non-invasive method for clinical reasoning and identifying a respiratory condition using only a stethoscope [1]. Regarding clinical respiratory examination skills, auscultation of lung sounds is often learned during medical school [2]. However, it is not easy to accurately listen to lung sounds and assess respiratory condition. In a study comparing the auscultation skills of medical students and physicians, there was no difference in skill, except for pulmonologists [3, 4]. This finding suggests that physicians may not have better lung auscultation skills than medical students.

Recent advances in digital stethoscopes have made it possible to record lung sounds and share them among multiple medical professionals, as well as to analyze lung sounds automatically, perform auscultation wirelessly, and provide telemedicine [5]. However, effective education for lung auscultation has not been developed. The skills of lung auscultation have been taught using simulators in addition to textbooks and audio sources [6]. Moreover, in recent years, it has become possible to listen to lung sounds through internet video-sharing sites and smartphone applications [7–9]. Medical students are often trained in auscultation at school, and after becoming doctors, may find on-the-job training to be their main learning opportunity for lung auscultation. Bernardi et al. examined the effects of simulator-based education on lung sounds and heart sounds and observed an improvement in the ability of auscultation of heart sounds, but no change in that of lung sounds [10]. The reason for this result could be that the participants were asked to choose the relevant lung sounds from a list of options, while the heart sounds were answered graphically. Therefore, the addition of visual information regarding lung sounds may improve lung auscultation learning.

74   Lung sounds have been visualized by spectrograms, which have been published in
75   textbooks, with the vertical axis representing sound pitch and the horizontal axis representing
76   time [11]. In the spectrogram, intermittent rales are represented by short vertical lines and
77   continuous rales are represented by horizontal lines. While it is useful to learn the
78   characteristics of lung sounds [12], spectrograms are not available in all institutions, and it is
79   difficult to visualize them with a personal stethoscope.

80   Herein, we created a simple graphical and mental visualization of lung sounds using a
81   combination of lines and circles in lung auscultation. This study, therefore, aimed to evaluate
82   the effect of educational methods of lung sound auscultation using visualization for medical
83   students in clinical clerkship (CC).

84

Materials and Methods

86   *Setting*

87   *Pre-clerkship course and CC*

88   In Chiba University's school of medicine, each grade comprises around 120 students. Medical
89   schools in Japan offer a six-year curriculum, with the final two years generally spent in CCs
90   [13]. In our university, the CC starts in December of the fourth year and ends in October of the
91   sixth year. Students are rotated from one department to the other every four weeks. In the third
92   year, before the CC, students attended a one-hour lecture on lung auscultation using a
93   simulator. Subsequently, each student performed self-learning using a textbook and/or the
94   simulator in preparation for the objective structured clinical examination (OSCE), which is
95   administered in the fall of the fourth year before CC.

96

97   *CC in the Respiratory Medicine department and study samples*

98   In our department's CC, groups of seven to eight medical students underwent a four-week

99   training program as members of a medical team of doctors and residents. All medical students

100   were assigned two to four patients during this four-week period and performed daily physical

101   examinations, including auscultation of the lungs.

102   A total of 89 medical students underwent CC in Respiratory Medicine at Chiba

103   University Hospital between December 2020 and November 2021. Informed consent was

104   procured during CC orientation from the participants for use of participants' test results

105   regarding lung auscultation as well as their questionnaire responses. Students who did not

106   answer all parts of the questionnaire or take the lung auscultation test were excluded from the

107   study. The 18 students who practiced in February and September 2021, during the COVID-19

108   pandemic in Japan, were also excluded, since the lectures and tests could not be held due to

109   hospital access restrictions.

110   This study was approved by the ethics committee of Chiba University (approval number

111   3425). The study database was anonymized.

112   ***Procedure of education on lung sound auscultation with visualization***

113   The lecture on lung auscultation lasted for an hour and was presented to all students on the first

114   day of CC in Respiratory Medicine. It consisted of an explanation of the mechanism of hearing

115   lung sounds and diseases, and auscultation of various lung sounds by students with the

116   simulator (Mr. Lung®, Kyoto-Kagaku, Kyoto). Mr. Lung® is a mannequin-type lung sounds

117   auscultation simulator widely used in medical schools in Japan [14].

118   The medical students were divided into two groups: a visualization group in which the

119   participants attended the lecture and visualized the lung sounds, and a control group in which

120   students only attended the lecture (Figure 1). The two groups were formulated on a rotational

121   basis (Visualization group: January, April, June, October, November; Control group:

122   December, March, May, July).

123

124   **Fig 1** Flow chart of the participants' selections and groups.

125

126   The students in the visualization group received additional training using a diagram of

127   graphically visualized lung sounds, as shown in Figure 2. In the diagram, the vertical axis

128   represents the pitch of lung sounds, and the horizontal axis represents the duration of lung

129   sounds. For respiratory sounds, the thickness of the line represents the loudness of the sound.

130   For the intermittent rales, each crackle is represented by a circle, and the height of the circle's

131   position indicates the pitch of the sound, while the size of the circle indicates the loudness of

132   the sound. Coarse crackles are presented as circles which are drawn at a lower position on

133   inspiratory and/or expiratory. Fine crackles are presented as circles that are drawn at the end

134   of the inspiratory and are concentrated at a high position. For continuous rales, a horizontal bar

135   was used. The height of the horizontal bar position indicates the pitch of the sound, and the

136   thickness of the bar indicates the loudness of the sound. Wheezes are mainly represented by a

137   horizontal bar at the high end of the expiration, and rhonchi are also mainly represented by a

138   horizontal bar at the low end of the expiration.

139

140   **Fig 2** The graphical visualization of lung sounds using a combination of lines and circles. (A

141   diagram showing inspiration and expiration was used to visualize the lung sounds. In the

142   diagram, the vertical axis represents the pitch of lung sounds and the horizontal axis represents

143   the duration of lung sounds. For respiratory sounds, the thickness of the line represents the

144   loudness of the sound. For the intermittent rales, each crackle is represented by a circle, the

145   height of position of the circle indicates the pitch of the sound, and the size of the circle

6

146 indicates the loudness of the sound. Coarse crackles are presented as circles that are drawn at

147 a lower position on inspiratory and/or exspiratory. Fine crackles are presented as circles that

148 are drawn at the end of the inspiratory and are concentrated at a high position. For continuous

149 rales, a horizontal bar was used. The height of position of the horizontal bar indicates the pitch

150 of the sound and the thickness of the bar indicates the loudness of the sound. Wheezes are

151 mainly represented by a horizontal bar at the high end of the expiration and rhonchi are also

152 mainly represented by a horizontal bar at the low end of the expiration.)

153

154   During the lecture, the students drew the various lung sounds they heard on a blank

155 diagram. Then, the students were instructed to mentally visualize lung sounds while performing

156 lung auscultation for patients.

157

158 ***Evaluation of the effects of education on lung sound auscultation with visualization***

159 *Questionnaire*

160 At the beginning and end of the department's CC, students responded to the following

161 questions on their experience and confidence with lung auscultation: (1) How is your current

162 lung sound auscultation ability? (2) Have you ever heard each lung sound from a patient? (3)

163 How confident are you in each of the lung sounds? Questions 1 and 3 were rated on a five-

164 point Likert scale, with scores ranging from 1 (Not confident [cannot listen at all]) to 5

165 (Confident [able to listen and distinguish between lung sounds and rales]). Moreover, for

166 questions 2 and 3, the students responded to each of the following: decreased respiratory

167 sounds, bronchial breathing, prolonged expiration, coarse crackles, fine crackles, wheezes,

168 rhonchi, squawk, and pleural friction rub. The classification of lung sounds was based on a

169 review by Bohadana et al. [15]. In addition to the above three questions, the students reported

170 their satisfaction levels with the education on lung auscultation at the end of CC in Respiratory

171 Medicine.

172 **Fig 3** Protocol for lung auscultation education and questionnaire and test regarding lung

173 auscultation.

174

175 *Performance of lung auscultation*

176 Students' lung auscultation performance was evaluated by an auscultation test of 10 cases using

177 the Mr. Lung™ simulator. The pre-test was performed at the beginning of CC in Respiratory

178 Medicine before the lecture. The post-test was performed on the last day of the third week of

179 the CC. The pre- and post-tests consisted of the same 10 sounds, while each case was given in

180 a different order (Table 1). In each case, one point was given for each correct answer of lung

181 sound abnormality and location. In four cases, in which more than one abnormal lung sound

182 could be heard, one point was given for each sound. Therefore, the maximum score was 25

183 points. Both the pre-test and post-test taken by the control group were multiple-choice forms

184 (Supplemental Figure 1A). The pre-test taken by the visualization group was a multiple-choice

185 form, while the post-test was a multiple-choice form that included a space to draw a figure

186 where there was an abnormality (Supplemental Figure 1B).

187

188 **Table 1** Abnormal lung sounds and where they were listened, as used in the lung auscultation

189 examination

Case of abnormal lung sounds	Location
Decreased breath sound	Left lower lung field

Coarse crackles	Right upper middle lung field
Coarse crackles	Bilateral upper lung fields
Fine crackles	Bilateral lower pulmonary region
Fine crackles	Bilateral whole lung fields
Wheezes, Prolonged expiration	Bilateral upper lung fields
Ronchi, Prolonged expiration	Bilateral upper lung fields
Wheezes, Ronchi, Prolonged expiration	Bilateral upper lung fields
Squawk, Coarse crackles	Right upper and middle lung fields
Pleural friction rub	Right middle and lower lung fields

190 The pre- and post-tests consisted of the same ten sounds, while each case was given in a

191 different order.

192

193   We then compared the answers in the questionnaire and the test scores between the

194 visualization group and control group.

195

196 ***Statistical analysis***

197 All results are expressed in terms of mean ± standard deviation (SD), unless otherwise

198 indicated. The Wilcoxon signed-rank test was used to compare the answers before and after

199 our education. Confidence in and scores on lung auscultation in the two groups before and after

200 our lecture were compared using analysis of covariance (ANCOVA), by adjusting the values

201 of the pre-questionnaire and pre-test results for each group. A p-value < 0.05 was considered

202 statistically significant. All statistical analyses were performed using JMP 15.0 software (Cary,

203 North Carolina, USA) and SAS software version 9.4 (SAS Institute, Cary, USA).

204

Results

In total, 71 students completed the lecture for auscultation of lung sounds. Of these students, three did not take the post-test and were therefore excluded from the study. Another three students were also excluded because their questionnaires had insufficient data. Finally, 65 students were included in the study (Figure 1).

Questionnaire

Based on an analysis of their responses, students' satisfaction level with our education was high in both groups, but slightly higher in the visualization group (visualization group: 4.5±0.1 vs. control group: 4.2±0.1, $p = 0.150$). There was no significant difference between the two groups in the experience of listening to each lung sound at the beginning and end of CC in Respiratory Medicine (Supplemental Figure 2).

Confidence in lung auscultation significantly increased in both groups (five-point Likert scale; visualization group, pre-test: 1.5±0.6 to post-test: 3.3±0.7, $p < 0.001$; control group, 1.7±0.6 to 2.9±0.8, $p < 0.001$). Confidence in lung auscultation after CC was found to be significantly higher in the visualization group than in the control group ($p = 0.028$; adjusted mean difference between pre- and post-test, 1.7±0.1 vs. 1.3±0.1, $p = 0.020$). In contrast, there was no difference between the two groups in self-assessment of listening to each lung sound (Supplemental Figure 3).

Results of tests of lung auscultation

The test score increased in both groups (visualization group, pre- 11.4±2.5 to post-test 15.1±3.5, $p < 0.001$; control group, 11.1±3.3 to 14.3±3.2, $p < 0.001$) as shown in Table 2. Although there was no difference between the scores of the pre- and post-tests of both groups

227   (pre-test, $p = 0.827$; post-test, $p = 0.290$), the visualization group scores tended to increase as

228   compared to that of the control group (adjusted mean difference between pre- and post-tests,

229   3.7±0.5 vs. 3.1±0.6, $p = 0.424$).

230

231

232 **Table 2** Changes in the confidence level pertaining to lung auscultation and the score of lung auscultation before and after education ($n = 65$).

	Visualization group (n = 35)	Control group (n = 30)	p-value
Confidence in lung auscultation, mean (SD)			
Pre-questionnaire	1.5 (0.6)	1.7 (0.6)	0.128
Post-questionnaire	3.3 (0.7)	2.9 (0.8)	**0.028**
Mean difference	1.8 (0.7)	1.2 (1.0)	**0.005**
Adjusted mean difference, least mean square (SE)	1.7 (0.1)	1.3 (0.1)	**0.020***
Score of lung auscultation, mean (SD)			
Pre-test	11.4 (2.5)	11.1 (3.3)	0.827
Post-test	15.1 (3.5)	14.3 (3.2)	0.290
Mean difference	3.7 (3.4)	3.2 (3.6)	0.623
Adjusted mean difference, least mean square (SE)	3.7 (0.5)	3.1 (0.6)	0.424*

233 * Analysis of covariance (ANCOVA) was performed and pre-score was adjusted.

234 (SD: standard deviation; SE: standard error)

Discussion

To the best of our knowledge, this is the first study to evaluate the effect of graphical and mental visualization of lung sounds in lung auscultation teaching during CC. There are two main findings. First, the visualization of lung sounds can improve medical students' confidence in their lung auscultation. Second, the visualization of lung sounds may improve medical students' ability to auscultate lung sounds, although the effect is limited. Our method does not require any special tools and can be easily and quickly implemented into usual education.

The visualization of lung sounds in lung auscultation can boost medical students' confidence in lung auscultation and help develop their lung auscultation skills. In the auscultation of heart sounds, the visualization of the timing of rhythm and murmur has been used [16]. Lung sounds have often been visualized in textbooks and reports [1]. Sestini et al. reported that a multimedia presentation of acoustic and graphic characteristics of lung sounds could improve lung auscultation learning among medical students. In their study, the questionnaire completed by the students indicated that the association of the acoustic signals with their visual image was useful for learning and understanding lung sounds [12]. However, there have been few opportunities to visualize lung sounds in daily practice. In addition to lectures using spectrograms and sound sources as presented in the report, we evaluated how simple graphical and mental visualization of lung sounds affected the lung auscultation of medical students in CC. Although the primary objective was to identify the lung sound abnormalities that were present in the patient, limited interest has been shown in determining the timing of breathing and/or the pitch of the abnormal sounds that can be heard. However, it is important to recognize the timing of breathing and the pitch of abnormal lung sounds for the evaluation of the respiratory status and for clinical reasoning. Moreover, there are four learning styles: visual, auditory, reading/writing, and kinesthetic [17]. The acquisition of auscultation

13

skills can basically be referred to as an auditory style of learning. Visualization of lung sounds can make lung auscultation learning multimodal by combining visual and auditory styles and this may help the students to be more aware of the timing and pitch of lung sounds. The visualization group showed greater confidence in lung auscultation, supporting this possibility. Since post-test scores were only around half the maximum number of points, only having confidence in lung auscultation will not suffice. However, the satisfaction level was also significantly higher in the visualization group, suggesting that visualization may have facilitated students' better understanding of lung sounds. Moreover, without confidence in lung auscultation, students may be hesitant to perform lung auscultation on patients. There is a possibility that students who are more confident in lung auscultation actively repeat lung auscultation more often. The repetitive practice of clinical skills can contribute to the retention of these skills [18]. In these students, auscultation skills may improve further in the long term.

The effect on the improvement score of lung auscultation was limited. Although there was no significant difference between the post-test scores of both groups, the visualizing group's scores tended to improve more than that of the control group. There are several possible reasons for the limited effect of our educational method. During the lecture, we presented a visualization of lung sounds and asked the students to draw a lung sound which they heard during the lecture. Then, the students were also instructed to imagine lung sounds during their daily practice of lung auscultation. However, it was not clear how often the students continued to visualize lung sounds in their daily practice. Instruction to repeatedly visualize lung sounds may be insufficient. It is possible that retention by instructing the students to repeatedly visualize lung sounds during their daily practice may have been more effective. Additional opportunities to draw lung sounds using the simulator or recorded lung sounds may have enhanced the effectiveness of our educational method; this possibility, along with the aforementioned one, could be addressed by future research. Furthermore, it is not clear how

the medical students actually heard the lung sounds from their answers that a lung sound abnormality was heard. By providing regular opportunities to capture lung sounds that can be heard using our method, it will be possible to clarify the gap between the findings of medical students and those of the supervising physician. As a result, lung auscultation can be effectively taught. In any case, our educational method of lung sound visualization does not require any additional tools, nor does it require much effort to implement. Although its effectiveness may be limited, it is a method that can be easily introduced into regular education and practice.

Study limitations

The present study has three main limitations. First, as it was performed at just one university in Japan, the number of students was small. Second, the experience of lung auscultation in other departments, the diseases of the cases that each student oversaw during CC in Respiratory Medicine, and each student's learning status may have influenced the results. Third, long-term effects have not been explored in our study.

Conclusion

The visualization of lung sounds may improve medical students' lung auscultation skills and their confidence in auscultation. Although the effect of lung sound visualization is limited, it can be undertaken without additional devices such as special simulators and serve as a useful educational strategy. Further improvement in teaching methods may increase the learning effect of visualization.

Supplementary Figure 1. Answer sheet for lung sound auscultation test.

A multiple-choice form (A) was used as the pre-test for the control and visualization group and the post-test for the control group. A multiple-choice form that combined a space in which to draw a figure where there was an abnormality (B) was used as the post-test for the visualization group.

Supplementary Figure 2. The responses of the visualization group ($n = 35$) and the control group ($n = 30$) regarding the experience of listening to each lung sound. C, control group; NS, not significant; V, visualization group

Supplementary Figure 3. The responses of the visualization group ($n = 35$) and the control group ($n = 30$) regarding self-assessment of listening to each lung sound.
