

Figure S2. Hyperfluorescence without histologic correlate, OS 2

A. Fluorescein angiography (FA, **A1**) venous phase, 11 months before death, shows multiple instances of hyperfluorescence. An optical coherence tomography (OCT) B-scan (green line) displays drusen, a double-layer sign (white arrowhead), choroidal hypertransmission, and hyperreflective foci (**A2**).

B, C. At 4 and 2 months before death, with 5 (**B**) and 6 (**C**) total injections, respectively, the lesion is stable, without intraretinal cysts.
