Supplementary Figure 1. Associations between plasma  $A\beta 42/A\beta 40$  ratio and enrichment of CSF tracer within CSF spaces at 24 and 48 hours. In the iNPH cohort (A-B), plots of associations between plasma  $A\beta 42/A\beta 40$  ratio and tracer enrichment in subarachnoid CSF spaces at (A) 24 hours and (B) 48 hours. In the total cohort (C-D), plots of associations between plasma  $A\beta 42/A\beta 40$  ratio and tracer enrichment in subarachnoid CSF spaces at (C) 24 hours and (D) 48 hours. For each scatter plot, the fit line is shown, including Pearson correlations and significance levels. Higher tracer levels at 24 hours compared to Pre (*i.e.* higher % change normalized T1 signal) is reflecting reduced clearance of tracer (interpreted as impaired glymphatic function), which was associated with lower  $A\beta 42/A\beta 40$  ratio, presumably due to reduced egress of  $A\beta 42$  to blood. Each scatter plot shows the linear fit line, including Pearson correlations and significance levels. Source data are provided as Source Data file.

Supplementary Figure 2. Associations between CSF-to-blood clearance parameters and plasma biomarker concentrations for the total cohort of patients. The associations between CSF-to-blood clearance pharmacokinetic variables and plasma biomarker concentrations are shown as Pearson's correlations (r) [95% confidence interval] for the total cohort of patients included in the study. Significance levels of Pearson correlation coefficients: \*P<0.05, \*\*P<0.01, \*\*\*P<0.001 (values in bold are statistically significant to P < 0.05). Source data are provided as Source Data file.

Supplementary Figure 3. Associations between plasma GFAP concentration and CSF-toblood clearance variables derived from our pharmacokinetic model. There was a significant positive correlation between average plasma concentration of GFAP and (A) absorption halflife ( $T_{1/2, abs}$ ), (B) time to maximum concentration ( $T_{max}$ ), and (C) lag-time ( $T_{lag}$ ). Hence, various measures of impaired CSF-to-blood clearance were associated with higher plasma GFAP concentration. Each scatter plots shows the fit line and the Pearson correlation coefficient with significance levels. Source data are provided as Source Data file.

Supplementary Figure 4. Associations between subjective sleep quality, assessed by the total score of the Pittsburg sleep quality index (PSQI), and plasma biomarker concentrations. There were no significant correlations between subjective sleep quality (measured as total score of PSQI) and plasma concentrations of (A) A $\beta$ 40, (B) A $\beta$ 42, (C) A $\beta$ 42/A $\beta$ 40 ratio, (D) T-tau, (E) GFAP and (F) NfL. Each scatter plots shows the fit line and the Pearson correlation coefficient with significance levels. Source data are provided as Source Data file.

Supplementary Table 1. Di	fferences in pla	sma metabol	ites between good (P	SQI score <u>&lt;</u> 5)	and poor sleepers	(PSQI score >6)
Sleep group	Ab40	Ab42	Ab42/Ab40 ratio	Log10Tau	GFAP	NFL
Good sleepers (n=10)	85.97±18.25	6.11±1.12	$0.073 {\pm} 0.009$	0.27±0.15	68.28±61.13	8.78±3.32
Poor sleepers (n=32)	88.30±21.98	6.19±1.28	$0.073 \pm 0.016$	$0.27 \pm 0.19$	$57.98 \pm 33.50$	$11.20 \pm 7.43$
