

New Phytologist Supporting Information

Article title: **Whole Genome Analyses Disentangle Reticulate Evolution of Primroses in a Biodiversity Hotspot**

Authors: Rebecca L. Stubbs^{1†}, Spyros Theodoridis^{2¶}, Emiliano Mora-Carrera¹, Barbara Keller¹, Narjes Yousefi¹, Giacomo Potente¹, Étienne Léveillé-Bourret³, Ferhat Celep⁴, Judita Kochjarová⁵, Giorgi Tedoradze⁶, Deren A.R. Eaton⁷, Elena Conti^{1*}

Article acceptance date: 26 September 2022

The following Supporting Information is available for this article:

Fig. S1 Multispecies coalescent phylogeny of *Primula* sect. *Primula* made in ASTRAL-III.

Fig. S2 gCF and sCF for all phylogenies.

Fig. S3 Chloroplast phylogeny of *Primula* sect. *Primula*.

Fig. S4 S-locus phylogeny of *Primula* sect. *Primula*.

Fig. S5 Fbranch (*fb*) analysis in Dsuite with multispecies coalescent topology.

Fig. S6 Ancestral range estimation under a Bayesian framework with phylogram.

Fig. S7 Ancestral range estimation under a Bayesian framework with chronogram.

Table S1 *Primula* specimens used in study.

Table S2 Fbranch values from Dsuite.

Table S3 Results from D_{FOIL}.

Table S4 D-statistics, f4-ratios, Z-score, and f4-ratio from Dsuite for all species trios.

Table S5 Posterior probabilities for every state in ancestral state estimation with phylogram.

Methods S1 Geographic Sampling.

Methods S2 Species networks estimation with NANUQ.

Methods S3 Supplementary D-statistic analyses.

Methods S4 Ancestral Range Estimation.

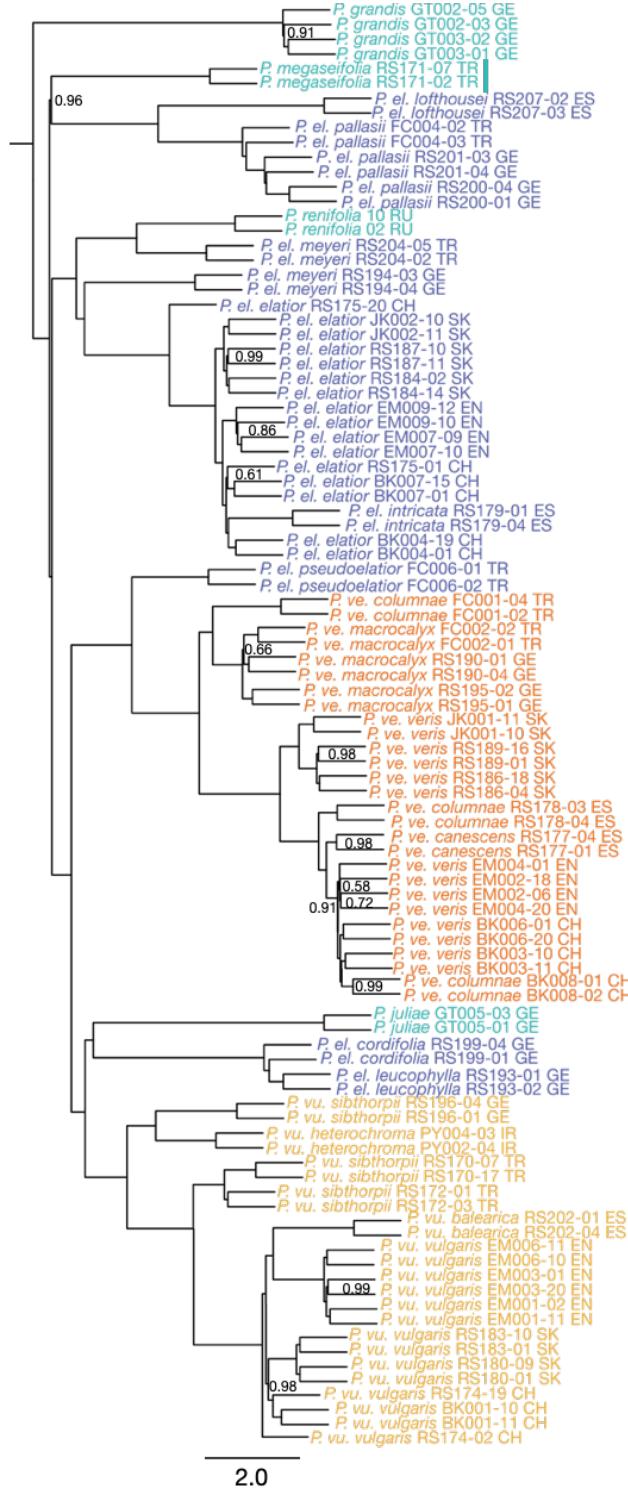

Fig. S1 Multispecies coalescent phylogeny of *Primula* sect. *Primula* made in ASTRAL-III. Branches with <1.0 local posterior probability (PP) are labeled. Branch lengths are presented in coalescent units. Outgroups not shown. Abbreviations: *P. ve.* = *P. veris*, *P. vu.* = *P. vulgaris*, *P. el.* = *P. elatior*, EN = England, CH = Switzerland, SK = Slovakia, GE = Georgia, TR = Turkey, ES = Spain, IR = Iran, RU = Russia.

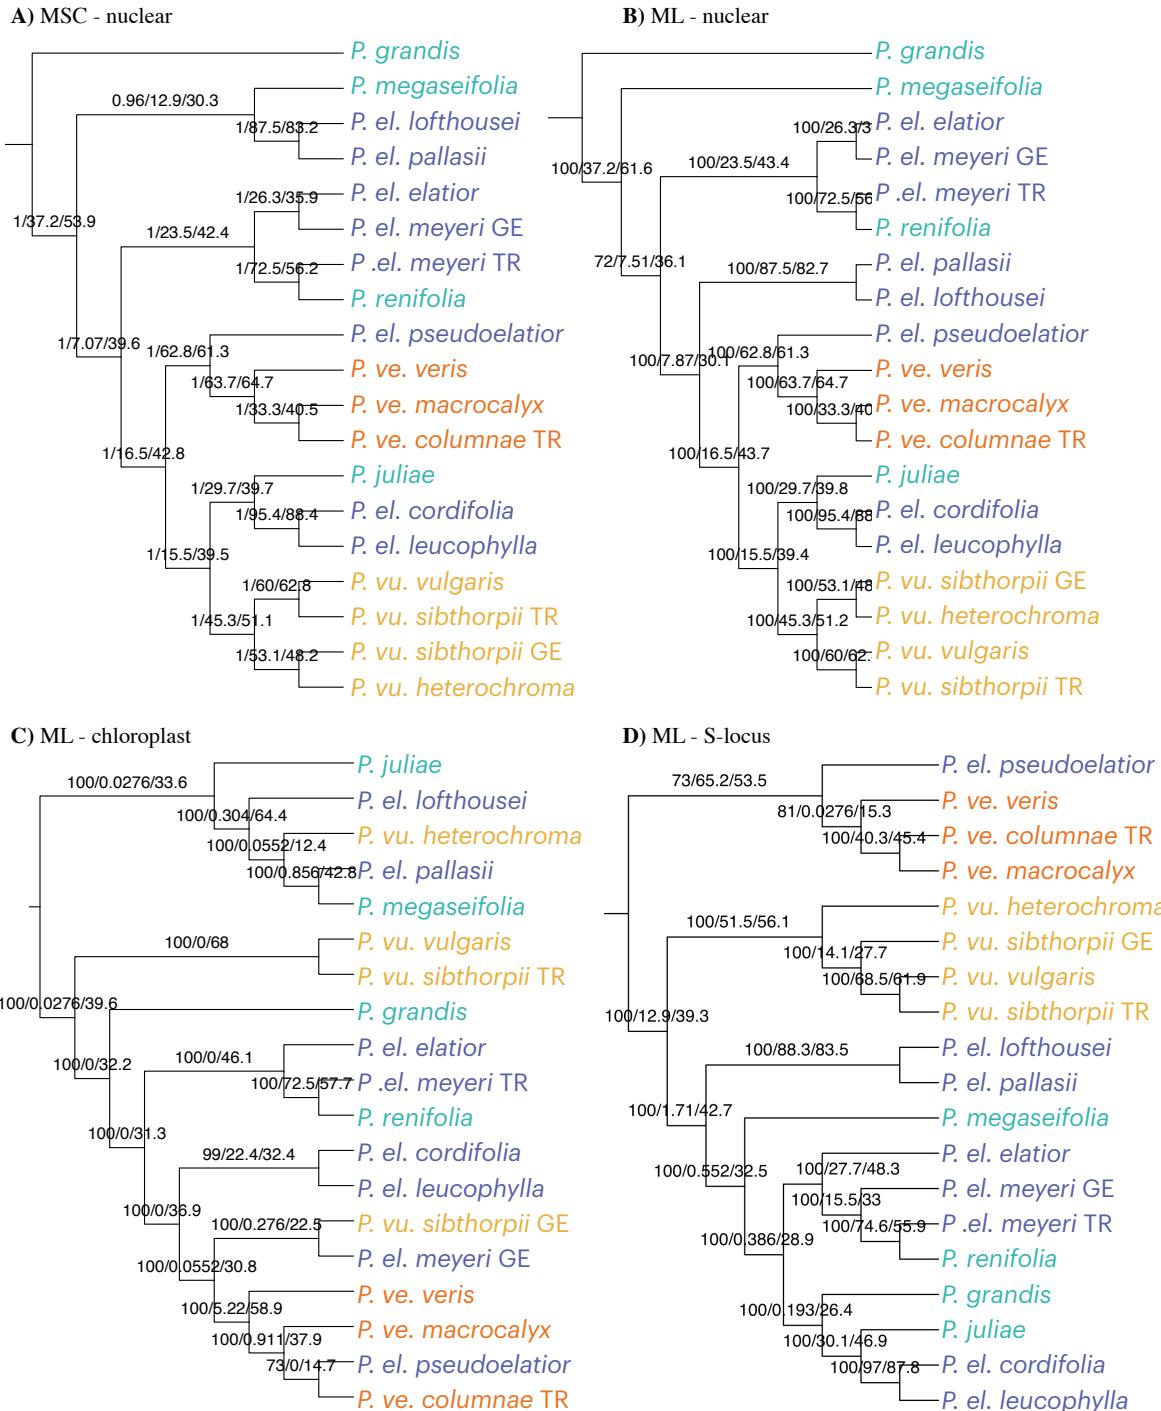

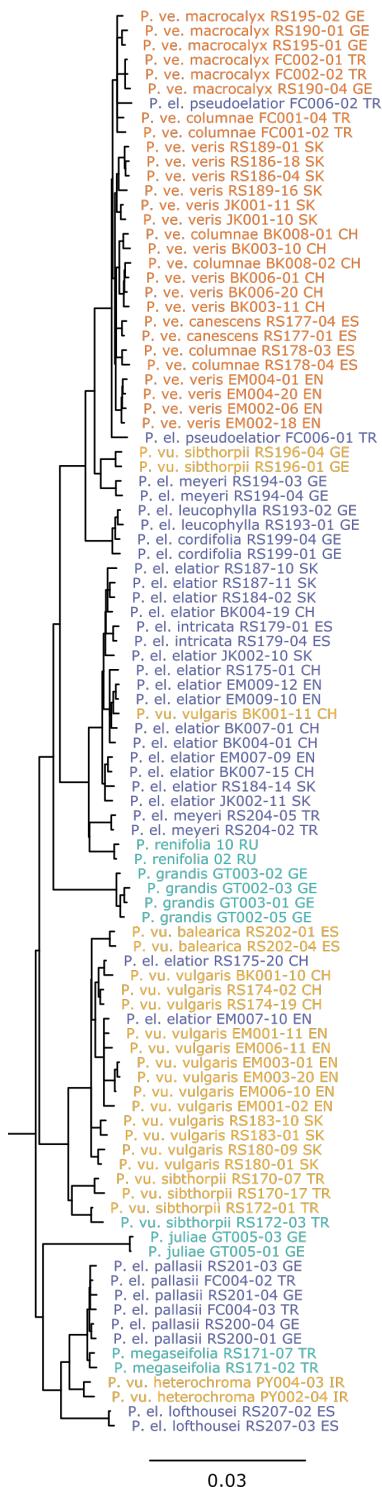

Fig. S2 Gene and site concordance factors (gCF and sCF, respectively) for different genomic compartments. Branch labels are as follows (from left to right): branch support, gCF, sCF. Branch support is local posterior probability in A and bootstrap support in B, C, and D. MSC = Multispecies Coalescent, ML= Maximum Likelihood.

0.03

Fig. S3 Chloroplast phylogeny of *Primula* sect. *Primula*. Branches with <90% bootstrap (BS) are collapsed. Outgroups not shown. Abbreviations: *P. ve.* = *P. veris*, *P. vu.* = *P. vulgaris*, *P. el.* = *P. elatior*, EN = England, CH = Switzerland, SK = Slovakia, GE = Georgia, TR = Turkey, ES = Spain, IR = Iran, RU = Russia.

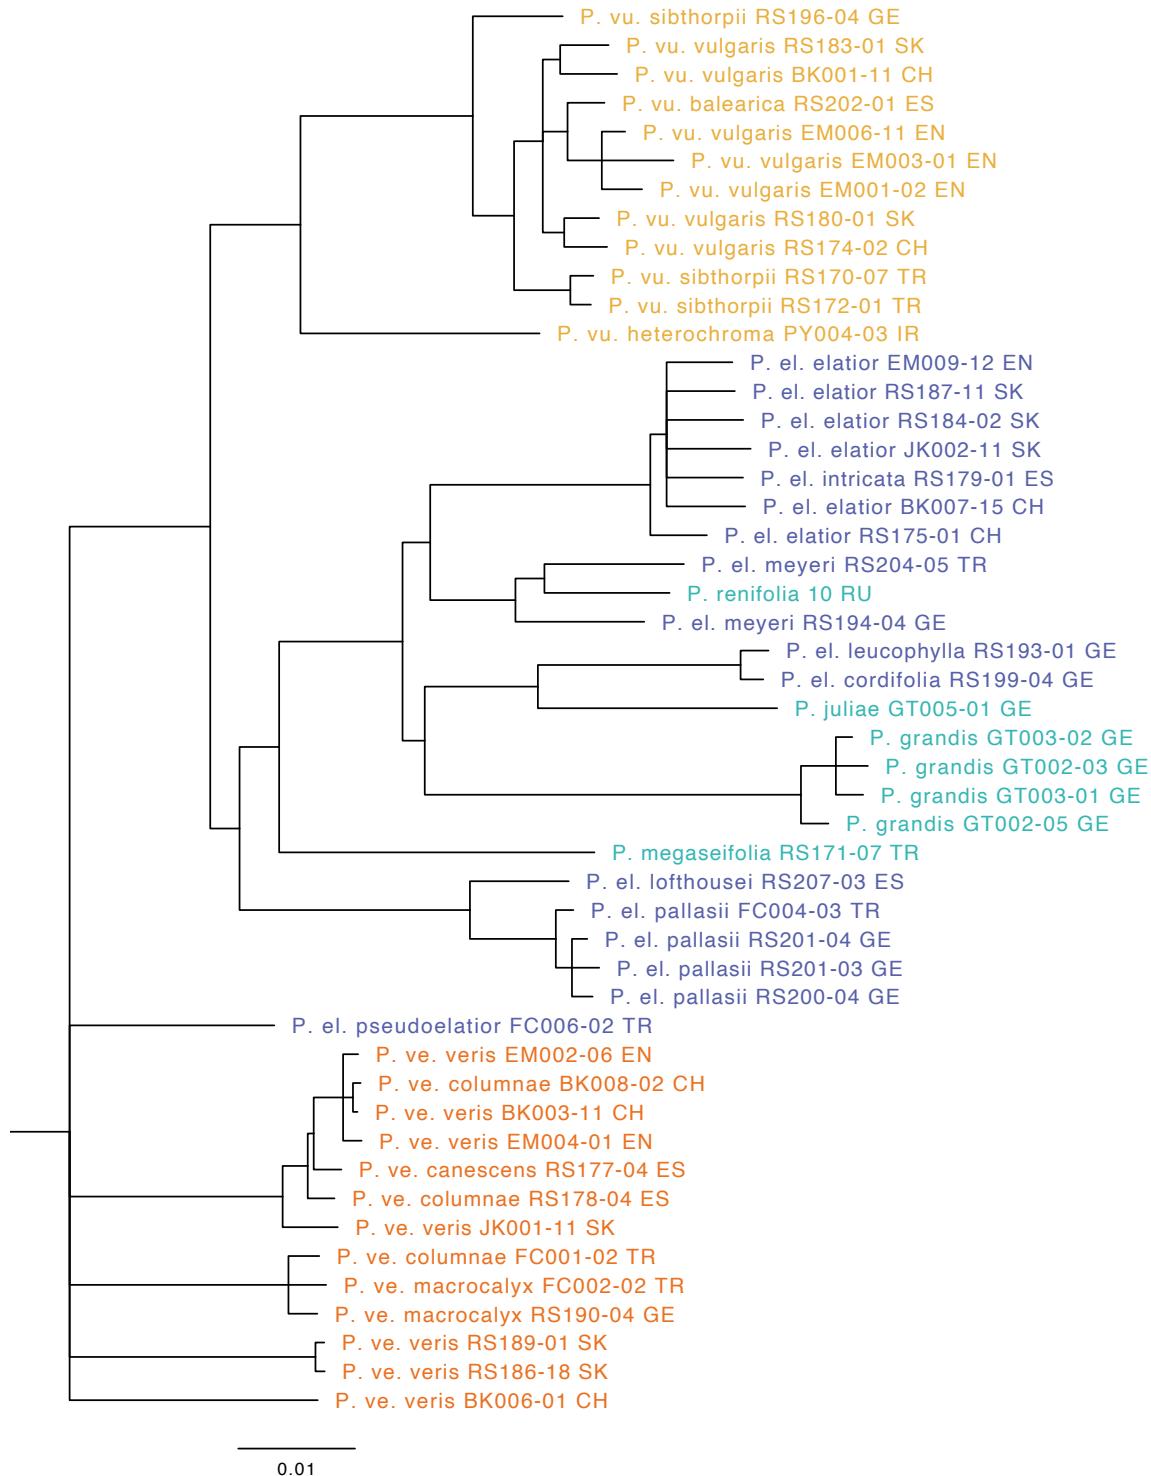

Fig. S4 S-locus phylogeny of *Primula* sect. *Primula*. Branches with <90% bootstrap (BS) are collapsed. S-locus phylogeny constructed from specimens with S-morph (short-styled) and homostylous specimens. Outgroups not shown. Abbreviations: *P. ve.* = *P. veris*, *P. vu.* = *P. vulgaris*, *P. el.* = *P. elatior*, EN = England, CH = Switzerland, SK = Slovakia, GE = Georgia, TR = Turkey, ES = Spain, IR = Iran, RU = Russia.

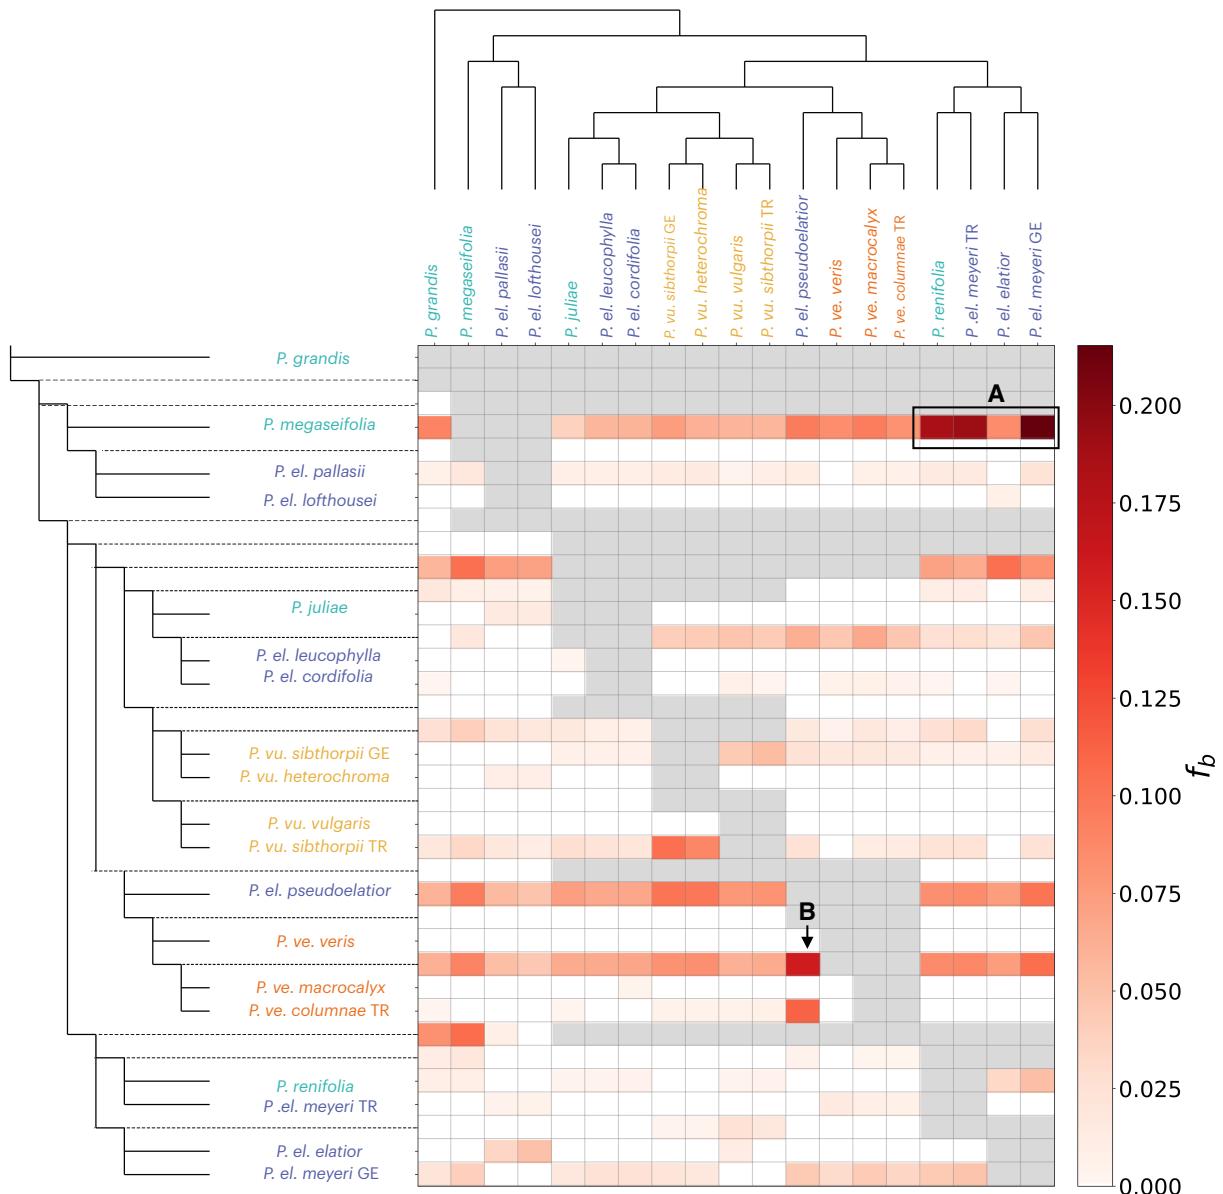

Fig. S5 Evidence of gene flow in *Primula* sect. *Primula* with multispecies coalescent topology. Results of the Fbranch (f_b) analysis in Dsuite. The values in the matrix signify excess allele sharing between the branch identified on the tree on the y-axis, which includes internal branches, and the species identified on the x-axis, relative to its sister branch. The light violet to dark purple gradient in the matrix refers to excess allele sharing, and white squares correspond to 0, non-significant values, or correspond to tests that are not consistent with the phylogeny. The tree is displayed in an ‘expanded’ form along the y axis, so that each branch, including internal branches, points to a corresponding row in the matrix. The two highest number of shared alleles are designated with A and B. A) Excess of shared alleles between *P. megaseifolia* and the ancestor of *P. el. elatior*, *P. el. meyeri*, and *P. renifolia*. B) Excess of shared alleles between *P. el. pseudoelatior* and the ancestor of *P. ve. macrocalyx* and *P. columnae*.

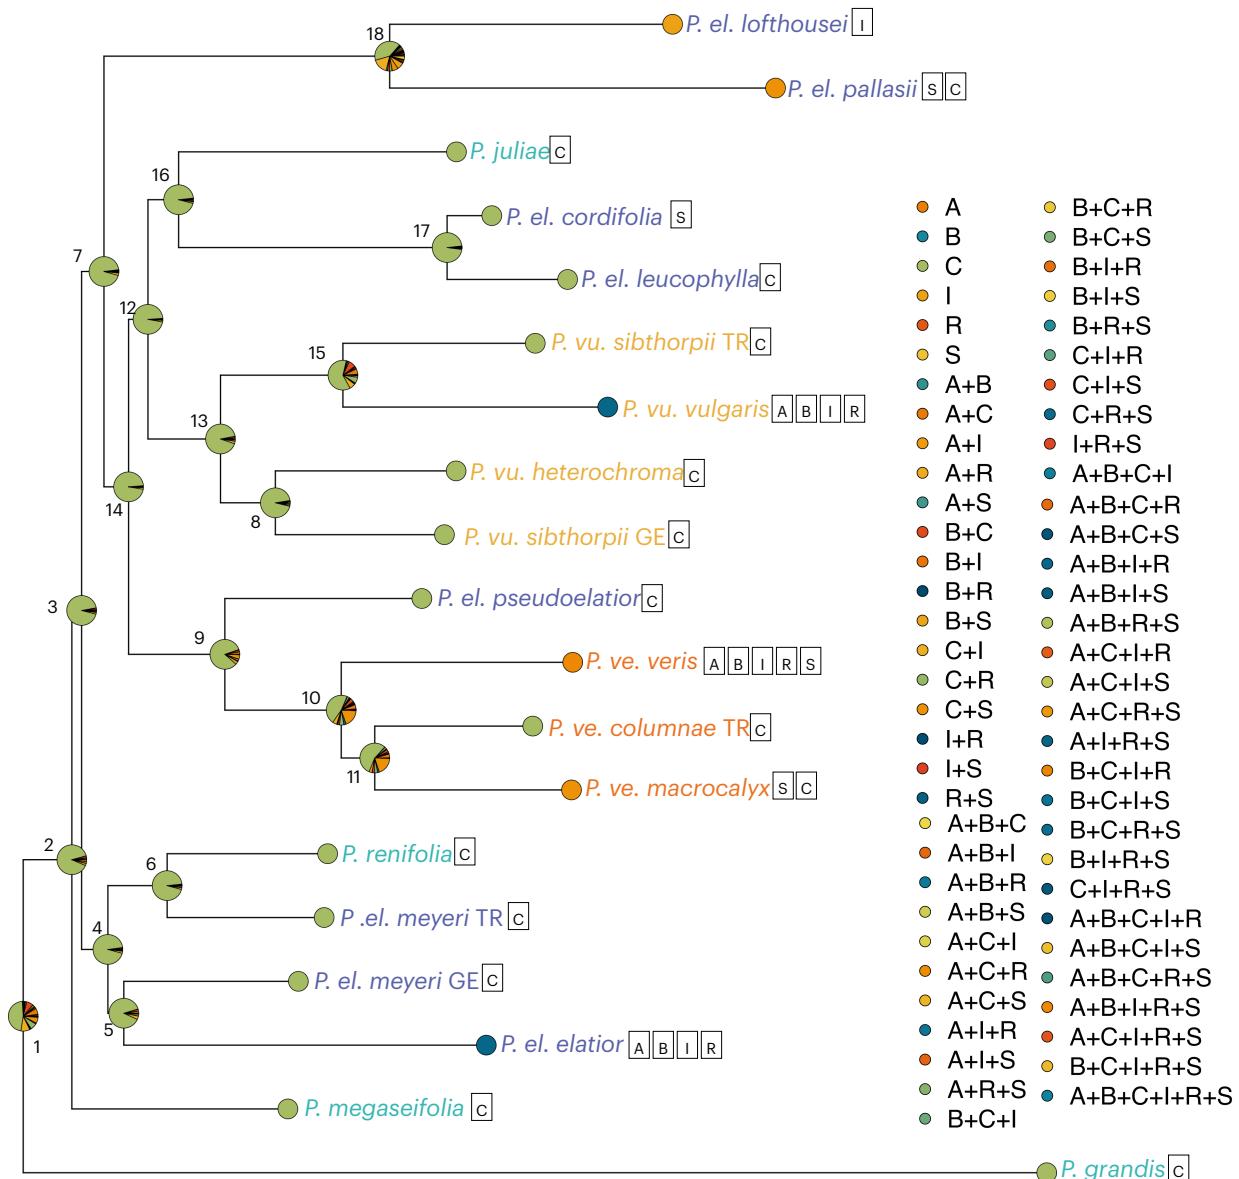

Fig. S6 Ancestral range estimation under a Bayesian framework with phylogram. Branch lengths in units of molecular divergence. Pie chart at each node corresponds to the probability of each state at that node. All nodes reconstructed the Caucasus (green) as the range with the highest probability. All nodes are numbered to correspond to Supplementary Table S5, which provides the probability of every state at each node. A = Alps, B = British Isles, C = Caucasus, I = Iberian Peninsula, R = Carpathians, S = Siberia/northern Asia.

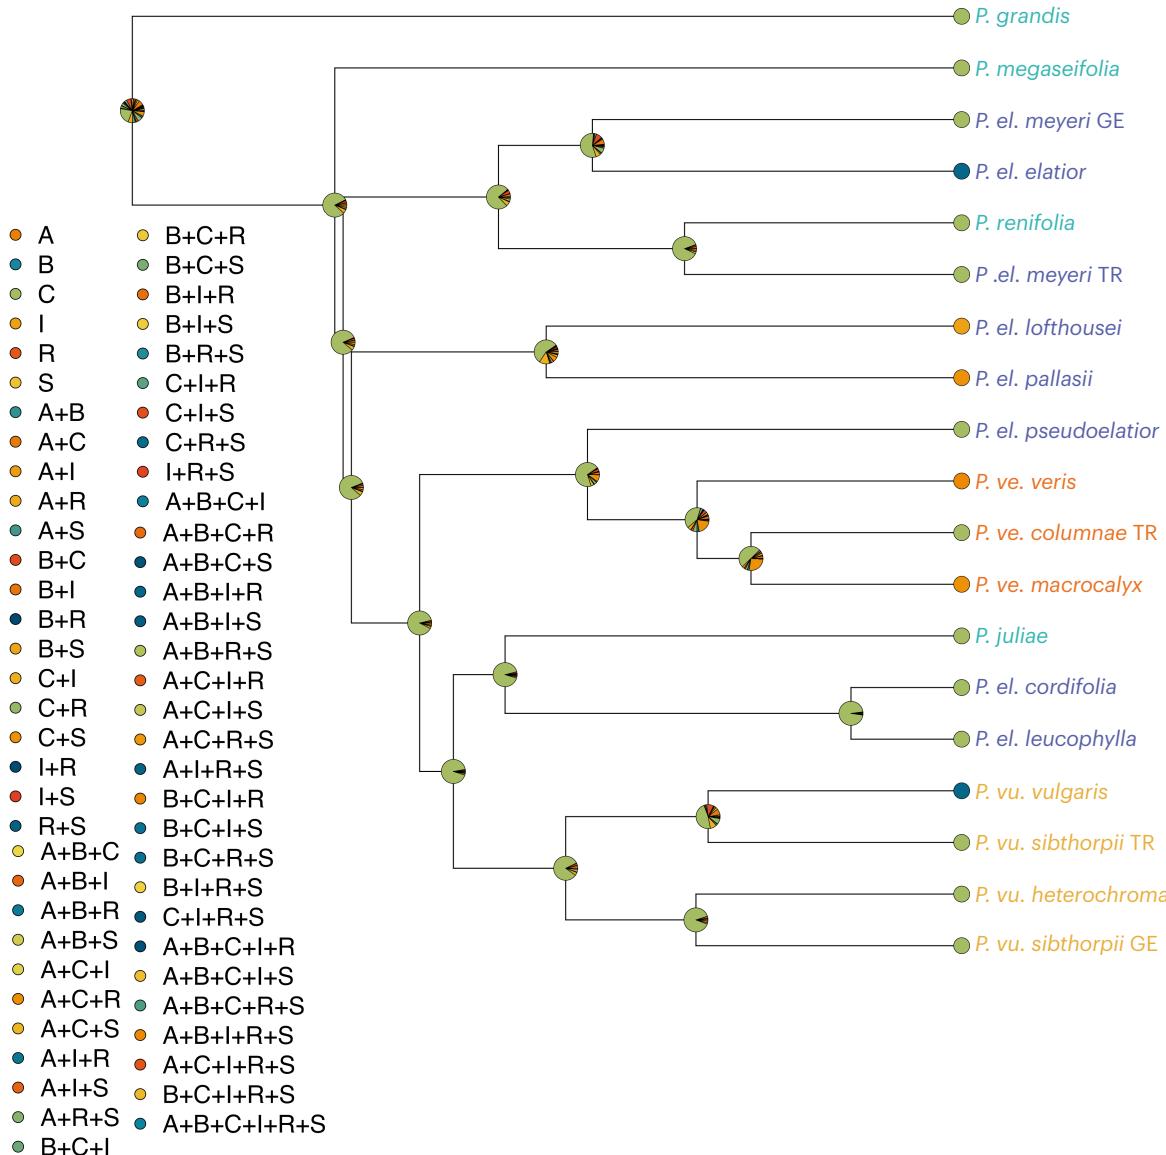

Fig. S7 Ancestral range estimation under a Bayesian framework with chronogram. Branch lengths in units of time. Pie chart at each node corresponds to the probability of each state at that node. All nodes reconstructed the Caucasus (C) as the range with the highest probability. A = Alps, B = British Isles, C = Caucasus, I = Iberian Peninsula, R = Carpathians, S = Siberia/northern Asia.

TABLE S1. *Primula* specimens used in study. A = Alps, B = British Isles, C = Caucasus, I = Iberian Peninsula, R = Carpathians, S = Siberia/northern Asia.

Methods S1 Study System and Geographic Sampling

Primula sect. *Primula* represents an ideal system to test the power of WGR to investigate sources of non-monophyly because of its distinctive biological characteristics and the wealth of available scientific resources. First, there have been extensive taxonomic studies of this clade for centuries (Linnaeus, 1753; Darwin, 1868; Smith *et al.*, 1984; Richards, 1989, 2003) culminating in the seminal monograph on *Primula* by Richards (2003). Second, the clade includes only seven species restricted to Eurasia, of which six are diploid and one is tetraploid, thus facilitating complete species and subspecies sampling and limiting analytical problems connected with extensive polyploidy. Third, a chromosome-scale reference genome is available for one species (*P. veris*; Potente *et al.* 2022) in the section, a necessity for high confidence and accuracy in calling single nucleotide polymorphisms (Fuentes-Pardo & Ruzzante, 2017). Fourth, hybridization has been amply studied in both natural populations and artificial crosses, indicating that gene flow among the three widespread species, possibly among all diploid species, is possible (Darwin, 1868; Smith & Fletcher, 1947; Valentine, 1947, 1961; Woodell, 1969; Kálmán *et al.*, 2004; Keller *et al.*, 2016, 2021; Tendal *et al.*, 2018). Finally, although *Primula* sect. *Primula* is distributed throughout Eurasia, the highest species diversity occurs in the Caucasus (Richards 2003), a remarkable biodiversity hotspot that is ranked as one of the most diverse and endangered ecoregions in the world (Mittermeier *et al.*, 2011).

Targeted fieldwork was conducted in 2018 to collect accessions covering the taxonomic and geographic diversity of *Primula* sect. *Primula* (Fig. 1A,B). All ingroup samples were collected in the field except for *P. renifolia*. Every currently recognized species and subspecies of *Primula* sect. *Primula* (following Richards 2003) was obtained from at least one population, while from every population we collected two individuals (Table S1). For most populations of the heterostylous taxa, we collected one S-morph and one L-morph plant. Multiple, geographically distinct populations of subspecies were sampled to capture morphological and molecular variation for *P. elatior*, *P. veris*, *P. vulgaris*, and *P. grandis* (Fig. 1; Table S1). Due to the limited distribution of *P. juliae* and *P. megaseifolia*, only one population was sampled for these species. Samples of *P. renifolia* were acquired from the Gothenberg Botanical Garden; these plants were originally obtained from their native range in the Caucasus region of Russia (collection number NCE230-1). Additionally, eight outgroup accessions used in previous phylogenetic analyses (Schmidt-Lebuhn *et al.*, 2012; de Vos *et al.*, 2014) were obtained from the

University of Zurich frozen tissue collection (Supplementary Table S1). This resulted in 98 ingroup and eight outgroup samples, totaling 106 specimens. All tissue was silica dried and herbarium accessions from every population were deposited at either Z, TBI, or ADO.

Methods S2 Species networks estimation with NANUQ

Species networks were estimated using the NANUQ algorithm as implemented in the R package MSCquartets (Allman *et al.*, 2019). NANUQ is based on an analysis of gene tree quartets, combining several statistical tests including quartet-based between-species distances appropriate to networks and splits graphs. Unlike pseudo-likelihood methods, NANUQ does not require the user to set an arbitrary limit on the number of hybridization events in the network. We tested multiple values of alpha and beta, as recommended by the authors, with the goal of testing for a signal of network cycles in the quartets (not shown). We selected an alpha of 5e-11 to impose a high standard for evidence of hybridization and a beta of 0.05, which requires stronger evidence for any resolution of the 4-taxon network. The NANUQ quartet hypothesis test showed that the selected alpha and beta were a good fit to our data because the quartet counts concordance factors (qcCFs) that are clustered close to the three-line segments in the simplex plot were recovered as being tree-like (Supporting Information Fig. A). In concordance, many of the qcCFs that were not close to three-line segments reject tree-like models and instead are in support of a network model (Supporting Information Fig. A), thus justifying a hybridization network (Allman *et al.*, 2019).

Quartet Hypothesis Test

NANUQ, $\alpha=5e-11$, $\beta=0.05$

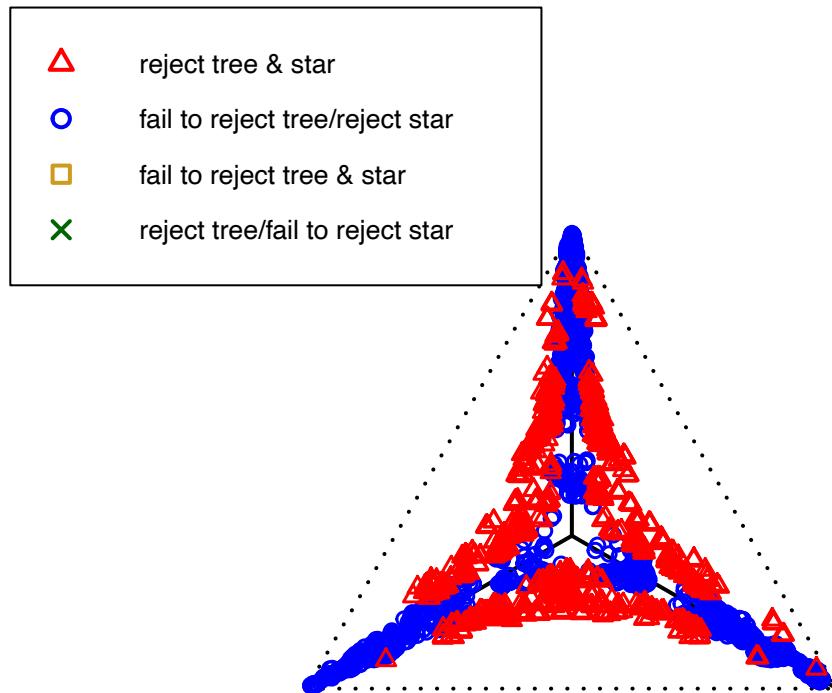

Fig. A. Simplex plot of NANUQ's quartet hypothesis test. The NANUQ quartet hypothesis test determines whether to view the quartet counts concordance factors (qcCF) as supporting (1) a star tree, (2) a resolved tree, or (3) a 4-cycle network. The results of the hypothesis tests suggest that the qcCFs close to the three-line segments are classified as tree-like (blue circles), and those farther away which were viewed as supporting a 4-cycle network (red triangles). Thus, the selected alpha ($5e-11$) and beta (0.05) are a good fit to our data because the qcCFs that are clustered close to the three-line segments in the simplex plot, which represent the true tree, are recovered as being tree-like.

Methods S3 Supplementary D-statistic analyses and information

We used D_{FOIL} (Pease & Hahn, 2015) to confirm admixture events identified using the F_b statistic. D_{FOIL} is similar to D-statistics except that it employs 5-taxon (quintet) trees consisting of (((P1,P2),(P3,P4)),O) rather than quartets. D_{FOIL} has been shown to accurately detect ancestral introgression events and exhibits exceptionally low false-positive rates (Pease & Hahn, 2015; Suvorov *et al.*, 2022). One caveat of D_{FOIL} is that it requires that the divergence time of (P3,P4) to diverge earlier in time than (P1,P2). Therefore, we selected the order of each quintet based on the chronogram in Supplementary Figure 6. Analogous to Dsuite, we applied D_{FOIL} to the entire genomic data set.

Introgression from a ghost lineage can significantly impact D-statistics, including the f4-ratio and Fbranch. Following the methods of Hibbins and Hahn (2021), we used the D-statistics generated from Dsuite for the entire genome (Supporting Information Table S4) to investigate the potential of ghost lineages having impacted our results. We focused on the two introgression events identified in Dsuite as having the highest F_b (Fig. 4). If one considers a quartet of [(P1,P2),P3], we can swap out the P1 for different, closely related species (hereafter referred to as P1-1 and P1-2). If P1-1 is the recipient of introgression from a ghost lineage this would result in P1-1 and P2 being sister taxa, and the incorrect inference of introgression between P2 and P3. In contrast, when running the same analysis with P1-2 (which has not received introgression from a ghost lineage) P1 and P2 will still be recovered as sister taxa, and we will not infer introgression between P2 and P3. Therefore, examined species quartets where P1 was either *P. megaseifolia*, *P. el. elatior*, *P. el. meyeri* GE, *P. el. meyeri* TR, or *P. renifolia* (corresponding to the introgression event identified in Fig. 4 letter A) and for *P. el. pseudoelatior*, *P. ve. macrocalyx*, or *P. ve. columnae* TR (corresponding to the introgression event identified in Fig. 4 letter B). We compared D-statistics, Z-scores, and p-values for these quartets. For any quartet with a significant D-statistic, we then examined if P2 and P3 had significant D-statistics if we swapped out another species (excluding those already identified as introgressed i.e., the other species in Fig. 4 A and B) for the target P1. In every case, multiple species (>4) exchanged for the target P1 resulted in significant D-statistics (Supporting Information Table S4). For further information, see Hibbins and Hahn (2021).

Methods S4 Ancestral Range Estimation

Methods used to reconstruct ancestral character states and ranges integrate information from branch lengths during the inference. Branch lengths can be specified in either units of time (chronograms) or units of molecular divergence (phylogenograms) (Litsios & Salamin, 2012; Matzke, 2013). Given that no fossil calibration points are available within our sampled taxa, we employed two methods to recover the ancestral range of this clade without a fossil-dated phylogeny. By using two methods, one employing a phylogram and the other employing a chronogram with relative dating, we can compare and contrast the results of each analysis to address the biogeographical patterns of *Primula* sect. *Primula*. In addition to conducting an ARE using a phylogram, we investigated if ARE with a time-tree recovered similar ancestral ranges as those run with a phylogram. To do this, we created an ultrametric tree through relative dating by putting a tight normal prior on the root of *Primula* sect. *Primula*. Specifically, we used the least square dating (LSD2) method implemented in IQ-tree, which incorporate the possibility of rate variation from branch to branch (To *et al.*, 2016). Dating is performed in three steps: 1) the best-fitting model is selected using ModelFinder, 2) the ML tree with branch lengths in number of substitutions per site is constructed, and 3) the branch lengths of the ML tree are rescaled, with rates varying from branch to branch, to build a time tree with a dated ancestral node. We set the root age to 10 with a standard deviation of 0.01. The output includes estimates of the substitution rate, the root date, and the dates of all internal tree nodes. This tree was used in ARE analyses identical to those employed for the phylogram, and the best model was also identified by the AIC as the transient model. All nodes recovered the Caucasus as the range with the highest probability.
