4. Summary of the model

Layer (type)	Output Shape	Param #
input_1 (InputLayer)	[(None, 300, 300, 3)]	0
block1_conv1 (Conv2D)	(None, 300, 300, 64)	1792
block1_conv2 (Conv2D)	(None, 300, 300, 64)	36928
block1_pool (MaxPooling2D)	(None, 150, 150, 64)	0
block2_conv1 (Conv2D)	(None, 150, 150, 128)	73856
block2_conv2 (Conv2D)	(None, 150, 150, 128)	147584
block2_pool (MaxPooling2D)	(None, 75, 75, 128)	0
block3_conv1 (Conv2D)	(None, 75, 75, 256)	295168
block3_conv2 (Conv2D)	(None, 75, 75, 256)	590080
block3_conv3 (Conv2D)	(None, 75, 75, 256)	590080
block3_conv4 (Conv2D)	(None, 75, 75, 256)	590080
block3_pool (MaxPooling2D)	(None, 37, 37, 256)	0
block4_conv1 (Conv2D)	(None, 37, 37, 512)	1180160
block4_conv2 (Conv2D)	(None, 37, 37, 512)	2359808
block4_conv3 (Conv2D)	(None, 37, 37, 512)	2359808
block4_conv4 (Conv2D)	(None, 37, 37, 512)	2359808
block4_pool (MaxPooling2D)	(None, 18, 18, 512)	0
block5_conv1 (Conv2D)	(None, 18, 18, 512)	2359808
block5_conv2 (Conv2D)	(None, 18, 18, 512)	2359808
block5_conv3 (Conv2D)	(None, 18, 18, 512)	2359808
block5_conv4 (Conv2D)	(None, 18, 18, 512)	2359808
block5_pool (MaxPooling2D)	(None, 9, 9, 512)	0
flatten (Flatten)	(None, 41472)	0
dense (Dense)	(None, 1)	41473

The model summary is a textual way to report information about the layers and their order in a convolutional network model. It also provides the output shape of each layer and the number of parameters propagated through the network. In our case, we can observe that an increasing number of parameters is obtained during the convolutional stage as a consequence of mathematical convolution in each layer. Conversely, max pooling layers do not increase the number of parameters, being involved only in reducing the computational cost and controlling overfitting. Finally, the number of parameters is brought to conversion through the fully-connected fatten layer and is kept unchanged in the dense one, where the sigmoid function acts to provide the prediction.

5. Confusion matrix and Cohen's kappa coefficient

Figure S4. Confusion matrix and Cohen's kappa expression

The confusion matrix is widely used in artificial intelligence and machine learning approaches. It returns a representation of statistical classification accuracy. Each column of the matrix represents the predicted values, while each row represents the actual true values. In our case we can see a perfect match between predicted stable cases and true one, as well as those belonging to the other subset. The Cohen's kappa coefficient, whose expression is reported in the equation above, is a statistical coefficient representing the degree of concordance in accuracy and reliability of a statistical classification. In our case κ is equal to 1, which means that the statistic represents the optimal case. (TP = true positive, TN = true negative, FP = false positive, FN = false negative, T = total)

6. Angles and Distance Analysis of RBD

The Dynamics of RBD: comparison of Distance and Angles analysis.

In green hues the UNSTABLE variants and in grey hues the STABLE variants. (A) Distance between the centers of mass (COMs) of the spike core and of the RBD of the UNSTABLE variants (WT, Alpha, Gamma and Omicron) represented in histograms. In magenta the fluctuation of monomer A with the RBD in the UP position, in green the monomer B (RBD down) and in blue the monomer C (RBD down). (B) Distance between the centers of mass (COMs) of the spike core and of the RBD of the STABLE variants (D614G, Beta and Delta). The graphs report on the x-axis the distances (Å) and on the y-axis the frequencies.

(C) The 3D angle between the spike core and of the RBD up in histograms. In the green box the UNSTABLE variants and in grey the STABLE variants. Histograms have on the x-axis the angles (Å) and on the y-axis the frequencies. In (D) and (E) are reported the comparisons between the distances (D) and the angles (E) in the most representative variants (WT, D614G, Delta and Omicron). The inset reports a simplified cartoon representation of the variables mentioned.

7. Distance fluctuations of all the variants in blocks

These Distance fluctuations matrices can be further simplified by dividing the protein according to its domains (the so-called "BLOCKS" that represent the domain of the spike protein for each monomer). Here we report these blocks:

- 1. NTD
- 2. RBD
- 3. CTD1
- 4. CTD2
- 5. Residues between the CTD2 and the FP
- 6. FP
- 7. Residues between the FP/FPPR and the HR1
- 8. HR1
- 9. CH
- 10. CD
- 11. Loop630
- 12. FPPR

Figure S5. Distance fluctuations of all the variants divided in blocks correspond to the domains of the protein.
