eFigure 1. HCA Healthcare Geographic Representation

Data Setting

HCA Healthcare is a large healthcare system with over 180 affiliated acute care facilities among its more than 2000 associated sites of care in 21 United States and the United Kingdom, as denoted on the map to the right. The majority of these facilities are medium to large community hospitals. Only data from facilities in the United States were collected.

COVID-19 Clinical Care Episode Diagram

eAppendix 1. Variables Identified as Confounders and Used for Adjustment

The list of potential confounding variables was identified through Stakeholder input and consultation with the HCA Healthcare / CHARGE Consortium Steering Committee.

Our causal model to define confounders was to enumerate all factors thought to be common causes of dexamethasone initiation and outcome, with particular emphasis on those factors that precede treatment and might be strongly related to outcome, as these are known to improve finite-sample efficiency, even if they don't play an explicit role in treatment decisions. From a clinical perspective, the question was: What factors might play a role in deciding whether to initiate dexamethasone that also impact mortality in the setting of COVID-19? Our team developed a list of such variables based on the literature and shared it with the HCA Healthcare / CHARGE Consortium Steering Committee.

The resulting list is as follows:

Community/Hospital level variables:

- Hospital volume (bed size)
- Hospital ICU volume (ICU bed size)
- Region (4 category variable)

Patient variables:

- Calendar time (measured continuously to capture changes over time)
- Time epoch: (Note Epochs are defined based on prior HCA research and periods 1-4 do not occur in our population)
 - 1="Epoch 1: March 2 - April 2, 2020"
 - 2="Epoch 2: April 3 - April 29, 2020"
 - 3="Epoch 3: April 30 - May 19, 2020"
 - 4="Epoch 4: May 20 - July 5, 2020"
 - 5="Epoch 5: July 6 - August 23, 2020"
 - 6="Epoch 6: August 24 - December 31, 2020"
 - 7="Epoch 7: Q1 2021"
 - 8="Epoch 8: Q2 2021"
 - 9="Epoch 9: Q3 2021"
 - 10="Epoch 10: Q4 2021"
- Age
- Sex
- Race/ethnicity (African American, Caucasian, Hispanic, others: American Indians, Asians) (race / ethnicity)
- Smoking
 - Smoking status categories:
 - Current smoker or smoker, current status unknown

- Former smoker
 - Never smoker
 - Unknown
- Minimum Spo2 at baseline
- BMI
 - BMI is derived from height and weight. Prior to calculating BMI we cleaned up height and weight using the following logic
 - Weight: values <50 lbs or >1000 lbs were set to missing
 - Height: values <3 ft or >8 ft were set to missing

- Medical history

For the following conditions we only used historical data (i.e. information from diagnosis history dataset which includes historical diagnoses captured in the EHR for the included patient population from January 1st 2018 to date, as well as any encounter that occurred before their index COVID encounter):

- Prior stroke
- Prior revascularization
- Prior myocardial infarction
- Prior pulmonary embolism
- Charlson comorbidity index

Historical procedures only:

- Prior dialysis

The conditions below could occur historically as defined above on page 4 or also on their index COVID encounter:

- Hypertension
- Hyperlipidemia
- Coronary artery disease (CAD)
- Diabetes
- Pre-diabetes
- Obesity
- Autoimmune disease
- Structural lung disease defined as a composite of:
 - Asthma
 - Chronic obstructive pulmonary disease (COPD)
 - Sarcoidosis
 - Interstitial lung disease (ILD/IPF)
- HIV/AIDS
- Cancer including the following separately:
 - Lymphoma / Leukemia
 - Solid tumors / malignancy
- Chronic Kidney Disease (CKD)

Factors that may vary over the hospitalization. These were evaluated at their most recent value upon eligibility for a particular cohort.

- Vital signs
 - Daily minimum oxygen saturation (SpO₂)
 - SpO₂/FiO₂ ratio. SpO₂ to FiO₂ ratio was calculated for each patient using the lowest SpO₂ and highest FiO₂ of the day.
 - Fraction of inspired oxygen (FiO₂) was frequently missing and handled as follows. For those with missing FiO₂ in the no-oxygen group then missing was imputed to 21%. For those with missing FiO₂ in the oxygen group, liters per minute of oxygen (LPM) was used to impute FiO₂ by the following formula: 1 L/min = 24% FiO₂, and 4% FiO₂ for every 1 L/min added to that (Duprez F, et al. A New Formula for Predicting the Fraction of Delivered Oxygen During Low-Flow Oxygen Therapy. *Respir Care.* 2018 Dec;63(12):1528-1534. doi: 10.4187/respcare.06243. PMID: 30467224)
- Hospital COVID prevalence
 - Daily COVID numbers at the hospital divided by the hospital bed size (number of patients relative to hospital capacity) averaged over the past 7 days at the hospital
- Labs
 - Creatinine converted to eGFR (Cockcroft Gault)
- In hospital interventions
 - Time since baseline (since admission date of COVID-19 hospitalizations until eligibility for a particular cohort)
 - Intensive care unit (ICU) Status (daily binary variable: 1 if in the ICU and 0 otherwise, based on icu_start_date, icu_stop_date)
 - Modified WHO ordinal scale: used to define cohorts (effectively non-parametric adjustment)
 - 2 = no supplemental oxygen received
 - 3 = received low-flow supplemental oxygen
 - 4 = received non-invasive or high-flow oxygen (CPAP, BIPAP)
 - 5 = received invasive mechanical ventilation
 - 6 = ECMO
- In hospital medications
 - Anti-coagulation (Heparin or Enoxaparin)
 - Prophylactic use
 - Treatment use
 - Remdesivir
 - Pressers (Norepinephrine, Epinephrine, Vasopressin, Phenylephrine, Dopamine)
 - Tociluzimab (in baseline table – too rare for modeling)
 - Baricitinib
 - Bamlanivimab + Etesevimab (in baseline table – too rare for modeling)
 - Casirivimab + Imdevimab (in baseline table – too rare for modeling)
 - Antibiotics
 - Azithromycin

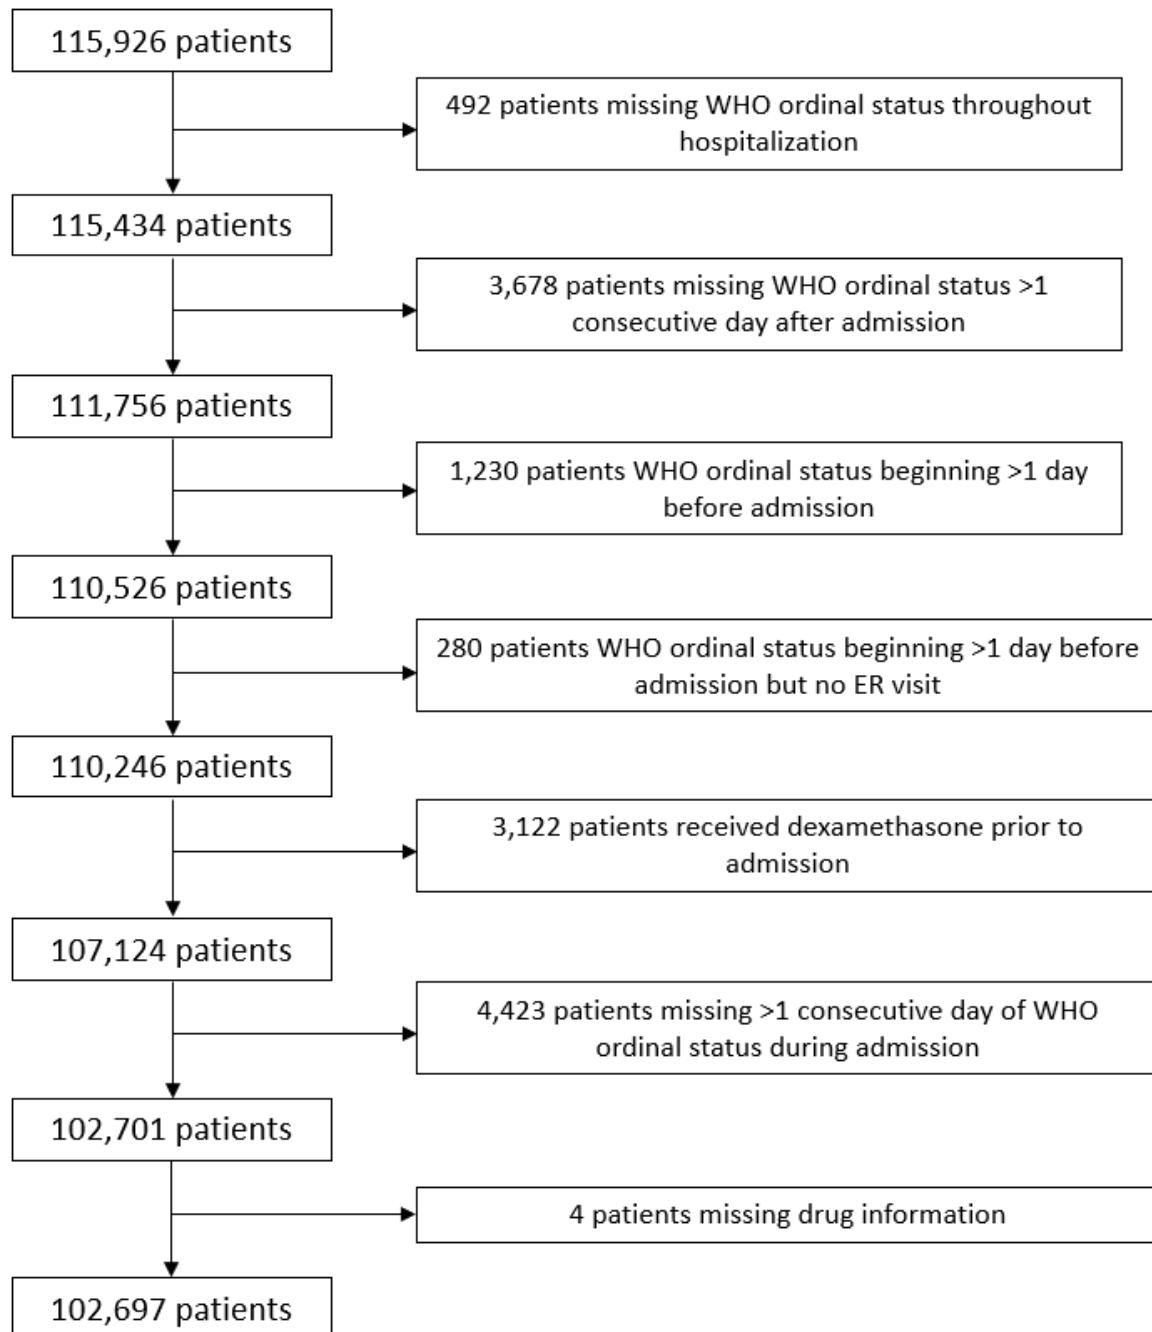

eAppendix 2. Study-Specific Inclusion and Exclusion Criteria

Starting population: All adults (age >17) hospitalized alive for at least 48 hours, between July 1, 2020

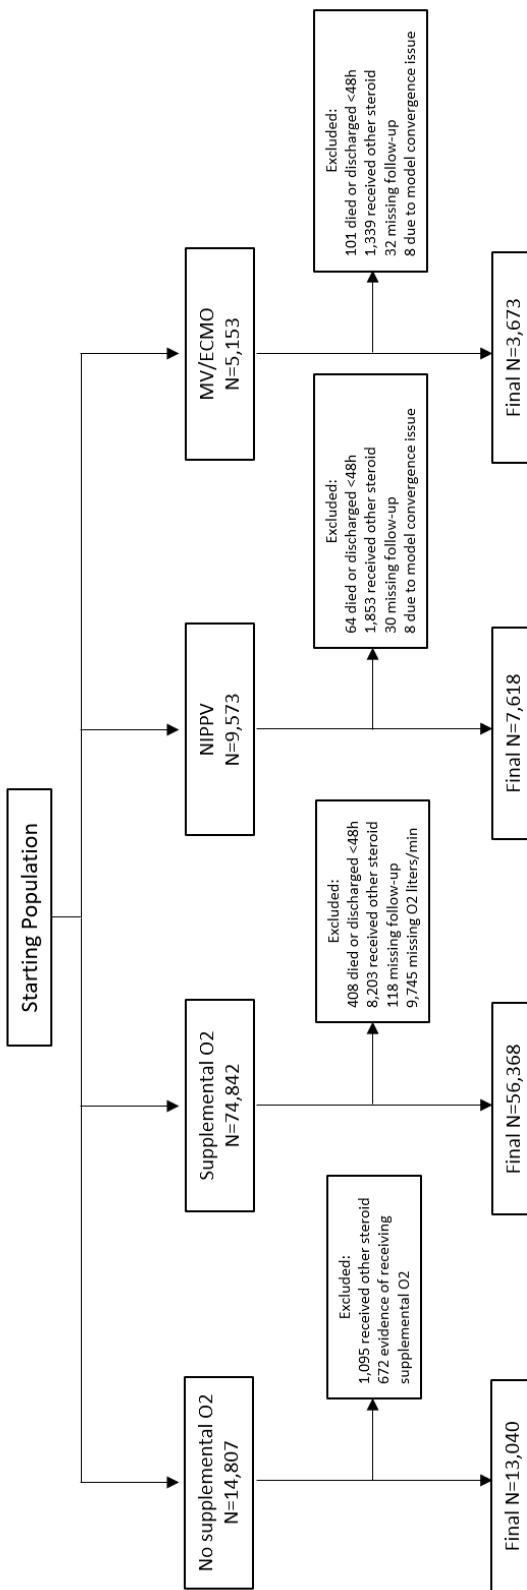

- October 31st 2021 for COVID-19 per CHARGE Consortium algorithm (if multiple hospitalizations meet the criteria this algorithm takes first as the index hospitalization) and having ICD-10 DX code for COVID-19 (in any position) AND ICD-10 DX code for respiratory illnesses (defined below)*

*ICD-10 DX Codes (in any position or rank, and A/I or F):

- COVID-19
 - U07.1,
- Acute Respiratory Illness
 - **J12.82 Pneumonia due to coronavirus disease 2019**
 - J12.89, Other viral pneumonia
 - J20.8, Acute Bronchitis due to other specified organisms
 - J40, Bronchitis not specified as acute or chronic
 - J22, Unspecified acute lower respiratory infection
 - J98.8, Other specified respiratory disorders
 - J80, Acute Respiratory Distress Syndrome
 - J96.00-J96.02, Acute Respiratory Failure
 - J96.2, Acute and chronic respiratory failure

* Standardized difference scores measure the effect size between Control and Dexamethasone (All Standardized difference scores have been multiplied by 100).

++ /ranks indicates standardized difference score was calculated using rank statistics for the row variable.

eAppendix 3. Handling of Missing Data and Multiple Imputation

Missing data was not imputed for univariable descriptive tables and rates of missingness are reported in Supplement E. Community variables (bed size and ICU bed size) were imputed to the median value. Missing data for the covariates that vary over the course of hospitalization was imputed as follows: Missing at baseline (day 0) was imputed to the value measured at day 1 if available. This reflects the possibility that admissions late in the day may not have data added until the next day. The baseline value was not imputed with data beyond day 1. Intermittent missing data was imputed with the last value carried forward method to reflect the assumption that clinical decisions would be based on the last measured value and thus, accurately measure confounding.

Missing data for covariates was imputed as follows. Multiple imputation was done by fully conditional specification methods with 10 imputed datasets. Imputation was done using all main effects listed as well as including both in hospital mortality and mortality/hospice endpoints. The models also accounted for oxygenation level. For all missing variables we used 30 burn-in iterations. Missing binary variables were imputed using the logistic method with a logit link. Whereas categorical variables were imputed using the generalized logit function. Lastly, continuous variables were imputed using the predictive mean matching method. The analysis of outcomes after multiple imputation was conducted in SAS PROC MI and accounted for variability introduced by imputation.

The results based on a single imputed data set and multiply imputed data set were essentially identical. We, therefore, moved forward with the single imputed data set for simplicity. For example, here is a comparison of overall results with differences in bold:

eTable 5. Adjusted Odds Ratios of Single Imputed Data Set and Multiply Imputed Data Set

	Single imputed data set	Multiply imputation analysis.
No oxygen	aOR 0.90, 95% CI 0.78-1.03	aOR 0.90, 95% CI 0.78-1.03
Supplemental oxygen	aOR 0.92 , 95% CI 0.86-0.98	aOR 0.91 , 95% CI 0.86-0.98
NIPPV	aOR 0.87, 95% CI 0.73 -1.04	aOR 0.87, 95% CI 0.72 -1.04
MV/ECMO	aOR 0.82, 95% CI 0.68-0.99	aOR 0.82, 95% CI 0.68-0.99
