eAppendix 1. Directed Acyclic Graph to Guide Model Selection

Given theory and prior findings in the literature, we postulated the mechanisms that could confound the association between youth incarceration in adult correctional facilities and early life death could be behaviorally related before the age of 12 including risk seeking, substance use, etc. Further, the mechanisms could also be associated with the environment in which the youth grew up before juvenile incarceration in an adult facility was measured. Unfortunately, due to data limitations we did not have access to proclivity for involvement in risky behaviors before the age of 12. Nonetheless, we believe that *arrested before the age of 18, number of arrests before the age of 18*, and *general health* serve as a proxy measures for related risky behaviors. In particular, being arrested as a youth represents involvement in serious risky behaviors that result in contact with law enforcement, which could influence both incarceration and the likelihood of early mortality. Similarly, general health serves as a self-reported indicator of risky health behaviors, which could influence both incarceration and the likelihood of early mortality.

While we cannot directly measure the environment in which the youth grew up, we believe childhood adversity, household income, parental incarceration, and the demographic characteristics of the youth serve as proxies and can be used to adjust for the potential confounding effects of the developmental environment. Childhood adversity and household income provide an indication of the likelihood of a youth being exposed to negative environmental circumstances, while parental incarceration is a direct indicator of having faced adverse childhood experiences. The demographics of the youth provide an indication of how they may be perceived by broader society.

In addition to the literature in the primary manuscript, the literature below helped guide the development of the Directed Acyclic Graph (DAG).
