

Supplementary Fig. 7. Healthy human donor CD4⁺ T cells were pre-activated with anti-CD3/CD28 for 48 hours and then re-stimulated with plate-bound anti-CD3 in the presence of increasing concentrations of soluble or plate-bound feladilimab or isotype control for 72 hours. IFN γ levels were then assessed from cell-free supernatants using Meso Scale Discovery (MSD)-based detection. Error bars represent mean \pm standard deviation; significance determined by unpaired student's *t*-test.
