

Supplemental Figure 2. Enrichment of tissue-specific signatures associated with gestational age in humans.

Tissue enrichment analysis was performed in all proteins associated with gestational age in human amniotic fluid, separately for up- and down-regulated proteins. For each enriched tissue, we summarized expression of all proteins over-represented in that tissue using a Z-score normalized to abundance at the earliest gestational age. The tissue-specific trajectories over gestational age are shown for upregulated (top) and downregulated (bottom) proteins separately for human samples (left) and for the same proteins in rhesus samples (right).
