Valvular heart disease	424.x	I34.x, I35.x, I36.x, I37.x, I38.x, I39.x
Thoracic and abdominal aortic aneurysms	441.x	I71.x

### **Supplementary Methods. Methodology for PM<sub>2.5</sub> exposure calibration**

The predicted PM<sub>2.5</sub> levels at grid cells were modeled and validated using monitored data. Therefore, it is possible that the prediction model's performance in terms of accuracy may be better for grid cells with monitors compared to those without monitors. To account for the fact that some areas had more PM<sub>2.5</sub> monitors than the others, we used a regression calibration approach with inverse probability weighting to correct for measurement error of the predicted PM<sub>2.5</sub>.

We created an indicator variable to determine the presence of PM<sub>2.5</sub> monitors in each ZIP code and year from 2000 to 2016 (coded as 1 if there were operating monitors and 0 otherwise). We performed a logistic regression using population density, racial demographics (percent Black, percent Hispanic, percent Asian), percent poverty, distance between industrial facility and the center of ZIP code, road density, normalized difference vegetation index (NDVI), and tree canopy as predictors. The fitted logistic regression was used to predict the probability of having at least one operating monitor for ZIP code-years. By taking the inverse of the probability, we obtained weight for each ZIP code-year combination. These weights were used to account for the sampling bias caused by the variation in the presence of monitors across ZIP code-years.

We collected daily monitored PM<sub>2.5</sub> data for the entire study period and aggregated them at the seasonal level, resulting in one observation for each season in each year. We then stratified the seasonal aggregates by census divisions (New England, Middle Atlantic, East North Central, West North Central, South Atlantic, East South Central, West South Central, Mountain and Pacific regions), season, and elevation (above or below 75th percentile), resulting in 72 strata.

We aggregated predicted PM<sub>2.5</sub> values for the days corresponding to the available monitored data and stratified them in the same manner as the monitored data. These predicted values were then linked to the monitored data by season, year, and ZIP code. The estimated weights were linked to those aggregates by ZIP code and year. The calibrated PM<sub>2.5</sub> levels were obtained as below:

- a. Within each of the 72 strata, we randomly generated 1,000 bootstrap samples. Each bootstrap sample had the same number of observations as the original stratum.
- b. For each bootstrap sample, we regressed the monitored PM<sub>2.5</sub> against the predicted PM<sub>2.5</sub> and other variables using simple linear regressions and incorporating the estimated weights:  $E(PM_{2.5\ monitored}) = \beta_0 + \beta_1 PM_{2.5\ predicted} + \beta_2 wind\ speed + \beta_3 humidity + \beta_4 impervious\ surface + \beta_5 I(2000 - 2003) + \beta_6 I(2004 - 2007) + \beta_7 I(2008 - 2011) + \beta_8 I(2012 - 2016)$ .

The betas for each stratum and bootstrap sample were used to obtain the calibrated PM<sub>2.5</sub> at grid cells given predicted values. Specifically, the predicted daily PM<sub>2.5</sub> at grid cells across the contiguous US were aggregated and stratified in the same way as the monitored data. This gave us 1,000 sets of calibrated PM<sub>2.5</sub> for each grid cell and season through 2000–2016 based on the betas for each stratum as  $PM_{2.5\ calibrated} = \widehat{\beta}_0 + \widehat{\beta}_1 PM_{2.5\ predicted} + \widehat{\beta}_2 wind\ speed + \widehat{\beta}_3 humidity + \widehat{\beta}_4 impervious\ surface + \widehat{\beta}_5 I(2000 - 2003) + \widehat{\beta}_6 I(2004 - 2007) + \widehat{\beta}_7 I(2008 - 2011) + \widehat{\beta}_8 I(2012 - 2016)$ . Given that our exposure of interest was annual PM<sub>2.5</sub>, we calculated the annual average calibrated PM<sub>2.5</sub> in each grid cell by averaging the values across the four seasons within the year and obtained 1,000 calibrated annual PM<sub>2.5</sub> levels in each grid cell and each year through the study period.

**Supplementary Table S2. Summary statistics of neighborhood-level covariates**

	<b>Mean</b>	<b>SD</b>
Proportion of population $\geq 65$ years of age living below the poverty line (%)	9.4	6.5
Population density (persons/mi <sup>2</sup> )	3109.2	8751.7
Median value of owner-occupied properties (USD)	201505.4	161483.5
Proportion of housing units occupied by the owner (%)	68.5	15.7
Proportion of the population identified as Hispanic (%)	11.6	16.7
Proportion of the population $\geq 65$ years of age who had not graduated from high school (%)	24.8	14.4
Mean BMI (kg/m <sup>2</sup> )	27.7	1.7
Percent of ever-smokers (%)	46.4	6.9
Annual lung cancer hospitalization rate ( $\times 10^4$ %)	3.9	3.7
Proportion of Medicare beneficiaries who received at least one hemoglobin A1c test per year (%)	83.3	4.9
Proportion of beneficiaries who had at least one ambulatory doctor visit per year (%)	78.4	6.1
Percent of beneficiaries who had at least one low-density lipoprotein cholesterol test per year (%)	79.6	6.3
Proportion of female beneficiaries who received a mammogram within a two-year period (%)	64.0	6.7
Proportion of beneficiaries who had at least one eye exam per year (%)	67.4%	5.8%
Distance to the nearest hospital (km)	6.7	7.6
Annual warm-season ozone from April–September (ppb)	44.9	5.8
Annual nitrogen dioxide (ppb)	18.7	9.8
Annual temperature (°C)	14.1	4.6
