eMethods

eMethods 1. Sample size estimation

The main effects of the 3-week rTMS interventions on psychomotor slowing (SRRS scores) was calculated in a repeated measures design including 2 assessment time points (Baseline, week 3) and four groups (lf-rTMS, iTBS, sham, waiting group-If-rTMS). Assuming a moderate effect size ($f = 0.23$) as indicated by our pilot data in a repeated measures ANOVA with moderate correlation between time points (0.5), a power of 0.95 and an alpha = 0.05, we needed 88 patients (22 per group).

eMethods 2. Trial registration

The trial was registered 25 days after enrolling the first participant. On March 12, 2019, IRB communicated final approval of the protocol. On March 22, 2019, the first participant provided informed consent. First rTMS treatment started on March 27, 2019. Trial registration was conducted on April 16, 2019. At this time, the first patient had just completed week 3 measurements, another two patients were receiving rTMS, while another two patients had been enrolled but withdrawn consent before starting the intervention. Thus, when the trial was registered, a total of 3 (3.4%) of the ITT population had been enrolled in the study.

Trial registration at clinicaltrials.gov included a minimal revision of the measurement organization that was conducted on April 25, 2019. No changes were made to the study design or outcomes after that.

Trial registration allowed entering the planned two primary outcomes (proportion of responders at week 3 and change in SRRS total scores from baseline to week 3). The IRB protocol only allowed for one primary outcome, i.e., change in SRRS total scores from baseline to week 3. Therefore, in the IRB protocol, the proportion of responders was stated as first of the secondary outcomes. This discrepancy between IRB and clinical trial registration was present from April 2019 onwards. In the presentation of the manuscript, we adhere to the clinical trial registration.

eTable 1. Inclusion/Exclusion criteria

Detailed inclusion and exclusion criteria.	
Inclusion criteria	<ul style="list-style-type: none">- 18–60 years old- Schizophrenia spectrum disorders according to DSM-5 with psychomotor slowing (SRRS score \geq 15)
Exclusion criteria	<ul style="list-style-type: none">- Substance abuse or dependence other than nicotine- Past or current medical or neurological conditions associated with impaired or aberrant movement, such as brain tumors, stroke, M. Parkinson, M. Huntington, dystonia, or severe head trauma with subsequent loss of consciousness- Epilepsy or other convulsions- History of any hearing problems or ringing in the ears- Standard exclusion criteria for MRI scanning and TMS; e.g. metal implants, claustrophobia- Any TMS treatment in the past 3 months- Pregnancy or breastfeeding

eMethods 3. Coils

All stimulations were delivered using either MagPro X100 including MagOption or MagPro R30 with theta burst option, both manufactured by Tonica Elektronik A/S, Denmark and distributed by Magventure A/S, Denmark. Each machine was consistently used at the same building of the department (MagPro X100 at Bolligenstrasse 111, MagPro R30 at Murtenstrasse 21). Patients were treated at the rTMS machine located closest to their inpatient stay.

For the real TMS-stimulations we used the MCF-B70 coil with transducer head dimensions of 180x116x50/67, magnetic field of 12kT/s in coil center at 20mm distance from coil surface and penetration depth (70V/m) of 34.0mm. In contrast, for sham stimulations, we used the MCF-P-B65 coil with transducer head dimensions of 172x94x53. These coils look almost identical and have identical sound emissions. However, the sham coil has no magnetic emissions.

eMethods 4. Secondary outcome rating scale subscores

Next to the total scores of the Positive And Negative Syndrome Scale (PANSS)¹, the Brief Negative Symptom Scale (BNSS)², the Bush-Francis Catatonia Rating Scale (BFCRS)³, we calculated secondary outcomes for subscores of those scales.

We considered PANSS positive (sum of items P1-P7), PANSS negative (sum of items N1-N7), PANSS general psychopathology (sum of items G1-G16), BNSS anhedonia, distress, asocial, avolition, affect, alogia, as well as BFCRS decreased activity (sum of

items 2, 3, 4, 12, 14, 19), BFCRS abnormal activity (sum of items 5, 6, 7, 8, 9, 10, 11, 13, 16, 17, 18, 20, 21)⁴.

eMethods 5. Actigraphy

The change in total physical activity during waking hours was measured with wrist actigraphy on the non-dominant arm (Move4 by movisens GmbH, Karlsruhe, Germany)⁵. Participants wore the instrument for > 24 consecutive hours. To this end, we used the activity level (activity counts/h of wake time)⁶, which has been calculated in multiple of our previous studies^{5,7-10}. Wake time of the day was confirmed based on inspection of the raw actigraphy data and crosschecking with the sleep/activity protocol participants provided.

eMethods 6. Coin rotation task

Manual dexterity of both hands was tested using the coin rotation task¹¹. We have applied this task before in samples of patients with schizophrenia and healthy subjects¹²⁻¹⁴. Participants were asked to rotate a Swiss 50-Rappen coin similar to the size of a US dime, between the first three fingers at a maximum speed with each hand during 3 trials of 10s, while being videotaped. Videos were analyzed by raters blind to allocation and time point of assessment. The first trial was a practice trial whereas the remaining two trials' scores were averaged and considered for the analysis. The following formula was used to calculate the score of each trial: CR score=half turns-[(coin drops×.10)×half turns]^{11,14}

eMethods 7. Randomization and allocation concealment

Prior to the first participant enrolled, we used a web-based tool “research randomizer” to perform permuted block randomization. Lists with random order of the four arms were generated. This was done to ensure that all four treatment arms receive the same number of participants. Permuted block randomization is preferred in sample sizes < 100 as in our trial¹⁵. Only the principal investigator (SW) had access to the randomization protocol that was stored on a login-secured computer.

Furthermore, group allocation of the participants was performed according to the block randomization lists by the principal investigator immediately after participants signed the consent form - and before baseline assessments. This way, information from baseline assessments were not available during the group allocation process.

The principal investigator was not involved in participant screening or recruitment. The principal investigator informed the part of the team who conducted the rTMS treatments (only one person for each participant) about group allocation. The psychiatrists who performed the assessments (DA, DBG, and AK) had no access to the randomization lists or treatment allocation process.

Allocation concealment was assured by keeping the treatment allocation written in sealed envelopes, locked at the lab office. In case of emergency, e.g. serious adverse event, the principal investigator could have broken the code and informed the clinical team about the treatment allocation. However, the study would have stopped in this participant. Fortunately, SAEs have never occurred during the study. See also IRB protocol chapter 6 for information on randomization, blinding, and unblinding.

In treatment arms 1 Hz, iTBS, and sham participants, raters, and the mental health professionals delivering treatment were blind to the stimulation used. Conversely, the participants randomized to the patient group knew that they were not receiving rTMS during the first three weeks. They were told to receive real rTMS in weeks 4-6. In the participant information it was stated that after the waiting period, patients would receive rTMS. But as the clinical trial registration is publicly available, participants may have noted that the waiting group would receive inhibitory stimulation through week 4-6.

.

eResults

eTable 2. Dropout reasons

Reason	1Hz n	iTBS n	sham n	waiting n	Total n
Withdrew consent	4	< 10*	3	6	15
Lost to follow-up	< 10*	0	0	0	< 10*
Treating psychiatrist's decision	< 10*	< 10*	0	0	< 10*
Adverse event	0	< 10*	0	0	< 10*

Note: * There were too few patients to provide an exact number without compromising data identifiability requirements.

Primary and secondary outcomes until week 3

eTable 11. Side-effects in the waiting group

	Waiting period n=22	1Hz over SMA post waiting period n=16
No side-effects, n (%)	-	4 (25%)
Dizziness, n (%)	-	< 10 (62.5%)*
Headache and neck pain, n (%)	-	7 (44%)
Fatigue, n (%)	-	8 (50%)
Other, n (%)	-	< 10 (62.5%)* - Perceived balance impairment - Tinnitus - Dry mouth
<i>Note:</i> * There were too few patients to provide an exact number without compromising data identifiability requirements.		

Figure 1. Course of anhedonia.

eFigure 2. Course of global functioning.

eTable 12. Baseline variables in the three sample versions.

Variable	ITT (≥1 stimulations, n = 88)				With baseline (n = 97)				With consent (n = 103)			
	1Hz	iTBS	sham	wait	1Hz	iTBS	sham	wait	1Hz	iTBS	Sham	wait
N	22	22	22	22	25	23	27	22	26	25	28	24
% male	72.7	54.5	40.9	36.4	72.0	56.5	40.7	36.4	69.2	60.0	39.3	37.5
Age in y	39.5	33.5	38.2	33.8	40.1	34.5	37.3	33.8	40.0	34.6	37.9	33.5
SRRS bl	24.7	23.3	24.2	23.7	24.8	24.1	23.7	23.7	No data without baseline			
biOLZ	13.3	13.4	22.6	15.8	13.1	13.9	21.9	15.8	No data without baseline			
bIDE	6.1	5.1	.5	.5	5.4	4.9	1.2	.5	No data without baseline			
mOLZ	14.5	12.0	22.9	15.4	14.2	12.6	22.2	15.4	No data without baseline			
mDE	3.6	2.3	.7	.1	3.2	2.2	1.4	.1	No data without baseline			

Note: SRRS bl: baseline value of the Salpetriere Retardation Rating Scale score; biOLZ: baseline olanzapine equivalents in mg; bIDE: baseline diazepam equivalents in mg; mOLZ: mean olanzapine equivalents in mg; mDE: mean diazepam equivalents in mg.

eTable 13. Results of the primary outcomes in n=88 (ITT) vs. n=97 (with baseline), covaried for sex, baseline and treatment medication.

		n = 88	n = 97	
Response rates in %	1 Hz	68.2	60.0	
	iTBS	36.4	34.8	
	sham	31.8	25.9	
	waiting	18.2	18.2	
Chi²-test, df=3	X ²	12.11	10.09	
	p-value	.007	.017	
Logistic regression adjusted for sex, baseline and treatment medication	Wald X ²	13.55	10.79	
	p-value	.004	.013	
	p-value OR 1Hz vs. iTBS	.005	.04	
	p-value OR 1Hz vs. Sham	.01	.03	
	p-value OR 1 Hz vs. waiting	<.001	.002	
ANCOVA SRRS scores at baseline and week 3 df=3	F (time x treatment arm interaction)	8.5	6.05	
	p-value	<.001	<.001	
Post-hoc tests	SRRS Week3	1Hz vs iTBS	.072	.179
		1Hz vs. sham	.017*	.192
		1Hz vs. waiting	<.001***	<.001***
		iTBS vs. sham	.448	.982
		iTBS vs. waiting	<.001***	.017*
		sham vs. waiting	.005**	.014*
<i>Note: ITT n = 88 includes patients receiving ≥ 1 stimulations (ITT). n = 97 includes all patients with baseline assessments. All missing data were computed with last observation carried forward (LOCF).</i>
