Supplementary Discussion

To unveil the physical and chemical changes of AZCS during sintering, thermogravimetric (TG) analysis with a heating rate of 2 °C/min was performed for AZCS. As demonstrated in Supplementary Fig. S7, it is obvious that a small amount of decomposition exists at 509 °C, and the mass retention is 88.85% at 600 °C, indicating that AZCS is relatively stable at this temperature. When the temperature is higher than 700 °C, serious decomposition of the material is observed (Supplementary Fig. S7).

Fig. S7. TG analysis. TG curves of AZCS.

Supplementary Discussion

X-ray photoelectron spectroscopy (XPS) was conducted to characterize the surface compositions and chemical states of AZCS and CZCS. The XPS survey spectra (Supplementary Fig. S8a) of AZCS and CZCS demonstrate the presence of Zn, Cd and S elements. The O $1s$ peak is due to the surface adsorbed H_2O and CO_2 molecules, as evidenced by FTIR (Fig. 2q). The C $1s$ peak is the surface contaminated carbon for calibration. As shown in Supplementary Fig. S8b, the S $2p_{1/2}$ and S $2p_{3/2}$ peaks of CZCS are located at 163.04 and 161.86 eV, respectively, which are in accordance with the reported literature[1]. In comparison, the S $2p_{1/2}$ and S $2p_{3/2}$ peaks of AZCS are negatively shifted by about 0.09 and 0.13 eV, suggesting the generation of S-vacancies on the surface of AZCS[2]. It is worth noting that both AZCS and CZCS show two small S $2p$ peaks at lower binding energies, which should be assigned to unbounded S^{2-} or bonded to a single Zn/Cd (dissociative S^{2-})[3]. The absence of S $2p$ peaks at higher binding energy positions (>164.0 eV) proves that no S-O sulfone bridges are generated on the surface of both samples[2]. As observed in Supplementary Figs. S8c, d, the Zn $2p$ and Cd $3d$ peaks in AZCS also exhibit a slightly negative shift compared to its CZCS counterpart, which further supports the formation of S-vacancies on the surface of AZCS[4]. In addition to peaks for bond formation in ZnCdS, both Zn $2p$ and Cd $3d$ spectra exhibit peaks for dissociative ions[5], which is consistent with the S $2p$ spectra.
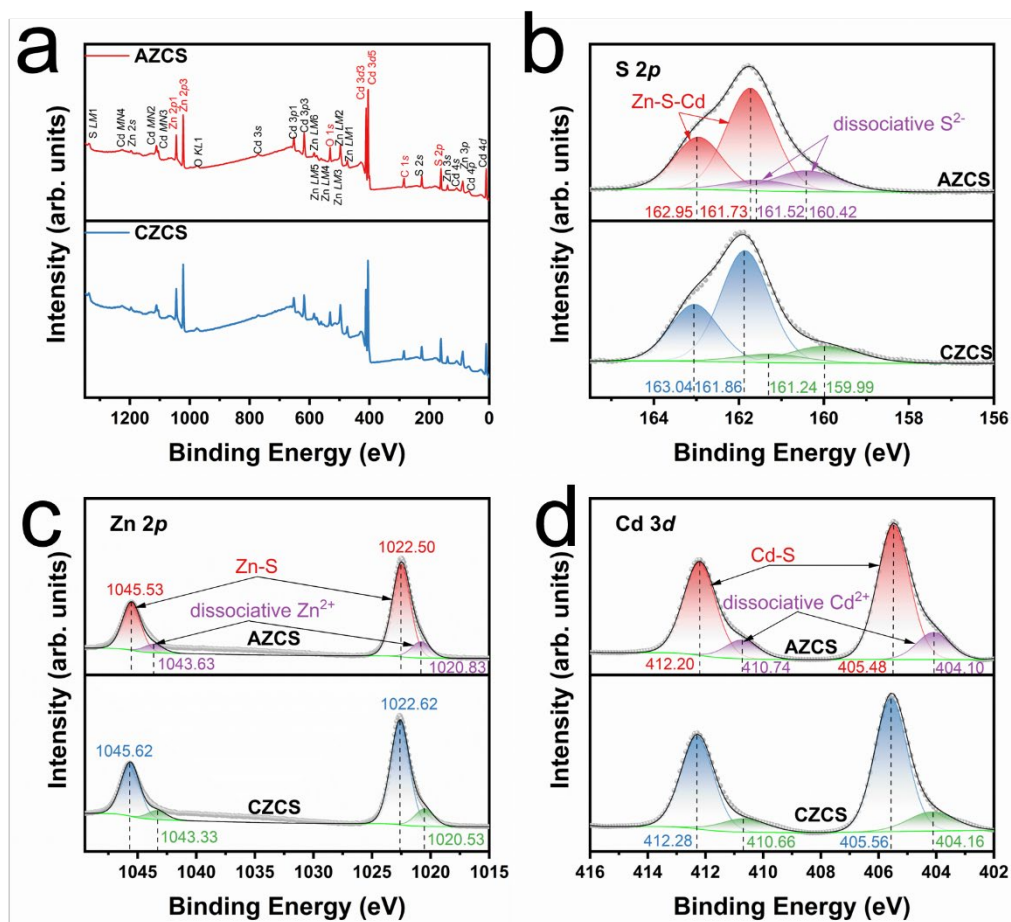

Fig. S8. XPS spectra. a XPS survey, **b** S 2*p*, **c** Zn 2*p* and **d** Cd 3*d* for AZCS and CZCS.

Supplementary Discussion

Since the interfacial binding between the photocatalyst and cocatalyst may also affect the photocatalytic activity, Raman spectroscopy was used to characterize the effect of Co-MoS$_x$ on the vibration modes of AZCS and CZCS functional groups, respectively. As shown in Supplementary Fig. S9, although Co-MoS$_x$ does not show its characteristic peaks on the Raman spectrum, it will affect the characteristic peaks of AZCS and CZCS, respectively. Since the intrinsic structures of AZCS and CZCS are different, the influence of Co-MoS$_x$ on their Raman peaks is also different. To exclude the effect of cocatalyst on the enhanced photocatalytic activity of AZCS compared to CZCS, the influence trend of different cocatalysts on the photocatalytic H$_2$ evolution performance of AZCS and CZCS was also investigated. As shown in Supplementary Figs. S10, 11, when Co-MoS$_x$, MoS$_2$ and Pt were used as the cocatalysts, the ratios of the average H$_2$ evolution rates of AZCS and CZCS are 5.0, 4.7 and 4.03, respectively.

It is worth noting that without a cocatalyst, AZCS and CZCS also have photocatalytic H$_2$ evolution properties. In the first half an hour, the ratio of the H$_2$ evolution rates of AZCS and CZCS is 5.11, indicating that AZCS and CZCS have an inherent difference in photocatalytic H$_2$ evolution performance. Owing to the sluggish photocatalytic reaction without a cocatalyst, the difference between the photocatalytic performance of AZCS and CZCS gradually decreases. It should be mentioned that the photocatalytic H$_2$ production rate of AZCS gradually decreases with the irradiation time, while its CZCS counterpart exhibits a relatively stable photocatalytic H$_2$ production rate during the same irradiation time, indicating that AZCS without cocatalyst is less

stable than CZCS. These experimental results are consistent with the DFT calculations shown in Supplementary Fig. S2.

As shown in Supplementary Fig. S12, the color of AZCS without a cocatalyst appears dark green after 8 h of photocatalysis, while its counterpart with a Co-MoS$_x$ as cocatalyst is still yellow, indicating that cocatalyst is essential to accelerate surface photocatalytic reactions and thus alleviating the destroy of the photocatalyst itself by the photogenerated charge carriers.

**Supplementary Discussion**

To further understand the underlying mechanism for the excellent photostability, SEM and XRD were used to characterize the changes in morphology and structure of AZCS without Co-MoS$_x$ loading after 8 h of photocatalysis (denoted as AZCS-8h), AZCS photo-deposited with Co-MoS$_x$ before photocatalysis measurement (denoted as AZCS/CMS), AZCS with Co-MoS$_x$ added in each cycle during 5 cycles of photocatalytic reaction (denoted as AZCS/5-CMS), and AZCS with Co-MoS$_x$ added only in the first cycle after 5 cycles of photocatalytic reaction (denoted as AZCS/CMS-5). As shown in the Figs. S18, 19, no obvious change can be observed in both SEM images and XRD patterns, indicating the excellent stability of our newly developed AZCS photocatalyst.

Table S1. Summary of crystallinities of ZCS0, ZCSRT, ZCS200, ZCS400 and ZCS600.

Sample	ZCS0	ZCSRT	ZCS200	ZCS400	ZCS600
Crystalline area	100566	227895	317438	406843	584055
Tatol area	620775	702729	642978	619342	645222
Crystallinity (W_c)	16.20	32.43%	49.37%	65.68%	90.52%
Error	1.62%	1.39%	2.26%	2.90%	1.25%

Table S2. The calculated AQY of AZCS and CZCS at different wavelengths.

Wavelength	AZCS		CZCS	
	H_2 evolution in 30 min (μmol)	Light power (mW cm^{-2})	H_2 evolution in 30 min (μmol)	Light power (mW cm^{-2})
405 nm	108.88	4.52	106.22	11.19
420 nm	159.87	6.70	177.64	21.46
455 nm	145.06	9.29	106.17	24.13
470 nm	101.38	9.14	66.34	20.77
500 nm	38.79	6.88	19.76	12.13
520 nm	22.79	5.91	10.27	11.16

$$
\begin{aligned}
AQY &= \frac{\text{the number of reacted electrons}}{\text{the number of incident photons}} \times 100\% \\
&= \frac{2 \times \text{the number of H}_2 \text{ molecules}}{\text{the number of incident photons}} \times 100\% \\
&= \frac{2 \times M \times N_A \times H \times c}{S \times P \times t \times \lambda} \times 100\%
\end{aligned}
$$

Such as, when λ = 405 nm:

$$
\begin{aligned}
AQY(AZCS) &= \frac{2 \times 108.88 \times 10^{-6} \times 6.02 \times 10^{23} \times 6.626 \times 10^{-34} \times 3 \times 10^{8}}{0.00452 \times 19.6 \times 1800 \times 405 \times 10^{-9}} \times 100\% \\
&= 40.35\% \\
AQY(CZCS) &= \frac{2 \times 106.22 \times 10^{-6} \times 6.02 \times 10^{23} \times 6.626 \times 10^{-34} \times 3 \times 10^{8}}{0.01119 \times 19.6 \times 1800 \times 405 \times 10^{-9}} \times 100\% \\
&= 15.90\%
\end{aligned}
$$

Supplementary Discussion

To further understand the change of $Co-MoS_x$ cocatalyst on AZCS with and without additional $Co-MoS_x$ cocatalyst in each cycle during photocatalytic H_2 production, ICP was used to investigate the amount of cocatalyst in $AZCS/Co-MoS_x$ and the supernatant liquid after each hydrogen evolution cycle. As listed in Supplementary Table S3, with additional $Co-MoS_x$ cocatalyst in each cycle, the Mo content in $AZCS/Co-MoS_x$ increases after 1, 5, and 10 cycles, and the supernatant liquid after 1 and 10 cycles also contains a small amount of Mo. However, without additional $Co-MoS_x$ cocatalyst in each cycle, almost no Mo signals can be detected in the supernatant liquid after photocatalytic hydrogen evolution for 5 cycles. In addition, the Cd contents in the photocatalyst and the supernatant liquid are almost unchanged from the 1st to the 10th cycle, indicating that AZCS itself is stable during the photocatalytic process. The above results indicate that not all $Co-MoS_x$ are attached to AZCS during the photo-deposition process, and the loading amount of $Co-MoS_x$ on AZCS is relatively stable during photocatalytic hydrogen evolution. However, the $Co-MoS_x$ cocatalyst gradually lose activity for H_2 evolution (Supplementary Fig. S16). During the photocatalytic process, the reducible support easily forms overlayers on the surface of the cocatalyst, thereby affecting the redox reaction on the surface of the photocatalyst[31,32]. Therefore, adding an appropriate amount of $Co-MoS_x$ cocatalyst during the photocatalytic process is necessary to maintain the activity for hydrogen evolution, thereby achieving excellent long-term stability.

Table S3. Summary of Cd and Mo contents in the supernatant liquid and photocatalyst after photocatalytic cycle.

Sample	Photocatalyst			Supernatant liquid		
cycle	1	5	10	1	10	5/N
Cd (mg)	20.23	19.64	20.25	0.108	0.0615	0.0716
Mo (µg)	36	48	84	13.6	8	1

5/N represents the supernatant liquid after the fifth hydrogen evolution cycle of the sample without adding Co-MoS$_x$ during each cycle.

Table S4. Summary of the R_{ct} values of ZCS0, ZCSRT, ZCS200, ZCS400 and ZCS600.

Sample	ZCS0	ZCSRT	ZCS200	ZCS400	ZCS600
R_{ct} **(KΩ)**	62.282	204.25	506.93	516.95	770.12
