Abstract

Background/objectives

We identified household members from electronic health records linked to National Child Measurement Programme (NCMP) data to estimate the likelihood of obesity among children living with an older child with obesity.

Methods

We included 126,829 NCMP participants in four London boroughs and assigned households from encrypted Unique Property Reference Numbers for 115,466 (91.0%). We categorised the ethnic-adjusted body mass index of the youngest and oldest household children (underweight/healthy weight <91st, ≥91st overweight <98th, obesity ≥98th centile) and estimated adjusted odds ratios (OR) and 95% confidence intervals (CI) of obesity in the youngest child by the oldest child's weight status, adjusting for number of household children (two, three or ≥4), youngest child's sex, ethnicity, and school year of NCMP participation.

Results

We identified 19,702 households shared by two or more NCMP participants (youngest children: 51.2% male). One third of youngest children with obesity shared a household with another child with obesity (33.2%; 95% CI: 31.2,35.2), compared with 9.2% (8.8,9.7) of youngest children with a healthy weight. Youngest children living with an older child with a BMI considered overweight (OR: 2.33; 95% CI: 2.06,2.64) or obese (4.59, 4.10,5.14) were more likely to be living with obesity.

Conclusions

Identifying children sharing households in primary care and linking to the NCMP provides novel insights into the shared weight status of children in the same household. Qualitative research is needed to understand how food practices vary by household characteristics to improve our understanding of how the home environment influences childhood obesity.

Key words

Childhood, obesity, households, BMI, electronic health records, record linkage

Key messages

There is a evidence to suggest that children living with older siblings with obesity are more likely to be living with obesity themselves. Less is known about the associations between the obesity status of child household members who are not biologically related.

What this study adds

We examined associations between child household weight status using novel linkages between school measurement and electronic health records. We showed that younger children living with an older child with obesity were more than four times more likely to live with obesity than those living with an older child with a healthy weight.

How this study might affect research, practice or policy

A household-level approach may potentially reach more children living with, and at risk of, obesity, to encompass a broader range of factors which may or may not influence obesity among all resident children.

Introduction

Childhood obesity is a major public health concern globally and reflects a complex number of factors, in particular socio-economic inequalities.(1) In England, more than one quarter of children leave primary school with overweight or obesity at a level of severity defined as in need of clinical intervention.(2)

A child's health, including their weight status, is significantly affected by the environment in which they live. Better understanding of households, their composition, and the health of children and adults who share households may provide novel actionable insights to address unhealthy weight in childhood.

Research has shown that child obesity is associated with parental obesity, where parental overweight or obesity is associated with an increased risk of obesity in their child.(3) This relationship is stronger for mothers than fathers.(4, 5) Less is known about the associations between the obesity status of child household members. Research investigating associations between siblings' weight status has reported inconsistent results.(6-13)

A 2023 systematic review of 13 studies identified that siblings' health-related behaviours and weight-related outcomes varied according to sibling sex and birth order.(14) Our understanding of how household composition, including presence of a sibling or other household children, as well as their weight status, influences childhood obesity could be improved with further research which includes all child household members and not just those who are biologically-related.

We identified individuals sharing a household using electronic health records and linked this to school measurement programme data to estimate the likelihood of obesity among children living with an older child with obesity. We also investigated whether household composition and size, and dwelling type, influenced the likelihood of childhood obesity.

Methods

Study population

Children in the first (Reception year) and last (Year 6) years of primary school are invited to participate in the National Child Measurement Programme (NCMP), which measures the height and weight of 4-5- and 10-11-

1
2
3 year-olds attending state-maintained schools in England. We linked 126,829 of 128,544 (98.7%) NCMP records
4
5 from four north-east London (NEL) local authorities (City & Hackney, Newham, Tower Hamlets, and Waltham
6
7 Forest) to general practice (GP) electronic health records (EHRs) via the Discovery Data Service (DDS).(15)
8
9

10 **Data sources**

11
12 We obtained pseudonymised NCMP data for the 2013/14-2018/19 academic years under data processing
13
14 agreements with each local authority public health department. As the available date of NCMP measurement
15
16 was restricted to month and year, we randomly assigned a day of measurement within term-time, excluding
17
18 weekends and bank holidays to avoid a spurious reduction in variance in age at measurement occasioned by
19
20 using the same fixed date of measurement for every child (R Studio; version 1.0.153; code available on
21
22 request).
23
24

25 Pseudonymised data were provided from the DDS which receives primary care EHR data on a daily basis from
26
27 all GPs in NEL. Demographic and clinical data recorded up to 1st November 2021 were extracted for NCMP
28
29 participants successfully linked to the DDS via pseudonymised NHS numbers created using
30
31 OpenPseudonymiser software.(16) All data were extracted and managed according to UK National Health
32
33 Service (NHS) information governance requirements.(17)
34
35

36 **Data processing**

37 *Residential Anonymised Linkage Fields*

38
39
40 Every addressable location in Great Britain is assigned a Unique Property Reference Number (UPRN). UPRNs
41
42 identify a place of residence at a granular level, identifying individual properties, for example houses or flats
43
44 within a block or building shell. UPRNs are allocated to GP-recorded addresses using the validated ASSIGN
45
46 algorithm,(18) and pseudonymised into Residential Anonymised Linkage Fields (RALFs) within DDS, using a
47
48 study-specific encryption key.
49
50
51

52 *Identifying household members at the child's school measurement date*

53
54
55 A household can only be defined at a single point in time because people living at an address may change over
56
57 time whilst the UPRN assigned to the residential dwelling stays the same.
58
59
60

1
2
3 A data extract containing all RALFs associated with any address(es) recorded in a child's EHR was extracted.

4
5 The file contained start and end dates of patient registration (enrolment) with the GP as well as address start
6
7 and end dates. Address start and end dates refer to the dates at which a patient lived at a particular address.

8
9 In most cases, these align with GP registration dates, but could differ, if for example, a patient moved house
10
11 but remained registered with the same GP.

12
13
14 Figure 1 describes the process for deciding which, if any, of the child's RALFs was the place of residence at the
15
16 time of their NCMP measurement. If the NCMP date of measurement took place between the most recent of
17
18 the registration and address start dates and the earliest of the registration and address end dates, the RALF
19
20 was considered to be the place of residence at the time of NCMP (supplementary Figure S1). Children without
21
22 a RALF at the time of their NCMP were excluded ($n=5,519$). We retained 115,466 children with a RALF at the
23
24 time of their NCMP measurement (referred to hereafter as index children).

25 26 27 *Identifying other National Child Measurement Programme participants in the household*

28
29
30 Similar steps were taken to identify other NCMP participants sharing a household with index children. We
31
32 started with 122,759 NCMP participants with at least one RALF (supplementary Figure S2) and included in
33
34 "dataset two".

35
36
37 Child pairs were excluded if the index child's NCMP measurement date did not fall within dataset two child's
38
39 RALF dates (supplementary Figure S3). Pairs were also excluded if the dataset two child was younger than the
40
41 index child or if the dataset two child's NCMP measurement was after the index child's. This process found the
42
43 youngest index child and identified the oldest NCMP participant living in the same household at the time of the
44
45 index child's NCMP measurement. Of 128,554 NCMP participants, 21,623 youngest/oldest child pairs were
46
47 identified.

48 49 50 *Identifying other household members and deriving household characteristics*

51
52
53 We identified all people who had ever lived at any of the RALFs identified in the dataset of youngest/oldest
54
55 child pairs. Steps were taken to determine household members at the time of the index child's NCMP
56
57 measurement (supplementary Figure S4). Full household information was identified for 19,702
58
59 youngest/oldest child pairs.
60

Outcome of interest

Obesity status of the index child was defined by the UK1990 clinical reference standard.(19) After application of ethnic-specific BMI adjustments,(20) a binary variable indicating obesity was defined as a BMI greater than or equal to the 98th age- and sex-specific centile. The index child's ethnic-adjusted BMI z-score was a secondary outcome.

Explanatory variables

Ethnic-specific BMI adjustments(20) were applied to the older child's BMI, and weight status determined according to the UK1990 clinical reference standard(19) categorising BMI into one of four mutually exclusive groups: "underweight" (<2nd centile), "healthy weight" (≥2nd to <91st centile), "overweight" (≥91st to <98th centile) or "obese" (≥98th centile). The older child's BMI z-score was also considered as an explanatory variable.

NCMP-recorded sex, local authority of the school where the child participated in the NCMP, academic year (September to July) and school year (Reception/Year 6) of participation in the NCMP were explanatory variables.

NCMP-recorded ethnic background was grouped into four mutually exclusive groups(21): White ('White British', 'White Irish', or 'any other White background'); Black ('Black African', 'Black Caribbean', or 'any other Black background'); South Asian ('Indian', 'Pakistani', 'Bangladeshi' or 'Sri Lankan'); and a combination of Mixed and Other ('any other ethnic background', 'mixed ethnicity', 'Chinese' or 'Asian other'). Where ethnic background was missing or not stated in the NCMP, ethnic background as recorded in the EHR ($n=11,077$) was used.

An area-level measure of relative deprivation - Index of Multiple Deprivation (IMD) decile(22) - was assigned to each NCMP record based on the postcode of the child's home address. IMD decile was concatenated into five quintiles ranging from most (1) to least deprived (5).

A categorical variable was derived from a count of people assigned the same RALF as the NCMP participant, grouping household size as follows: 2; 3-4; 5-6; 7-10.

1
2
3 We categorising household composition using a modified Harper and Mayhew method(23) by counting the
4 number of household members in three age brackets: 0-17 years (children), 18-64 years (working age adults)
5 and 65 or older (older adults) and grouping into: working-aged adults with children; a single working-age adult
6 with children; at least one working-age and one older adult with children (three generation household), or at
7 least one older adult with children (skipped generation household).
8
9
10
11
12

13
14 The property classification, as given by the ASSIGN algorithm, categorised properties into three groups: flats,
15 terraced houses, and other.
16
17

18
19 Sex concordance was coded either the same (when both children shared the same sex) or different (when the
20 two children had differing sexes). The time difference between the youngest and oldest children's NCMP
21 measurements was calculated as the time in months between the two measurements.
22
23
24

25 **Statistical analyses**

26
27
28 We estimated the prevalence of obesity among children living with an older NCMP participant and explored
29 variation by the weight status of the older child. We used binary logistic regression to estimate the likelihood
30 of obesity in the index child (odds ratio [OR] and 95% confidence interval [CI]) by the older child's weight
31 status, after accounting for individual and household characteristics. We conducted linear regression to
32 estimate the effect of a one unit increase in the oldest child's BMI z-score on the index child's BMI z-score. All
33 analyses, conducted using Stata (MP/15.0), were stratified by school year.
34
35

39
40

41 **Patient and public involvement**

42
43 This research was done without patient or public involvement. Neither were invited to comment on the study
44 design and were not consulted to develop relevant outcomes or interpret results.
45
46
47

48 **Ethics approval**

49
50
51 The analyses of linked pseudonymised NCMP and GP data were approved by the respective data controllers
52 under data processing agreements which allow linkage of pseudonymised NCMP data between the research
53 organisation and each local authority public health team. This study is a secondary analysis of de-identifiable
54 data and no further ethics approval was required.
55
56
57
58
59
60

Results

Index children were, by study design, more likely to take part in the NCMP in the Reception school year and in the more recent academic years (Table 1). Similarly, the oldest children were more likely to take part in the NCMP in Year 6 and in the earlier academic years (supplementary Table S1). Three quarters lived in households with adults of working age only, and more than half lived in flats (Table 2).

A greater proportion of index children with obesity were male, participating in the NCMP in Year 6 and in Tower Hamlets and Newham, and from South Asian ethnic backgrounds, compared with index children with underweight or a healthy weight (Table 3).

There was no variation in the number of children sharing a household or property classification by weight status (Table S2). A lower proportion of index children living with obesity lived in households with a single adult (12.5%; 95% CI: 11.2,14.0) compared with the proportion among children with an underweight/healthy weight status (14.9%; 14.4,15.5).

One fifth and one third of index children living with obesity shared a household with another child with overweight or obesity, respectively, higher than those with underweight or of a healthy weight (Table S3; Figure 2). Sex concordance, nor time difference between the index and older children's NCMP measurement dates, did not vary by weight status of the index child.

in adjusted analyses, index children living with an older child with overweight or obesity were more likely to be living with obesity. Conversely, those sharing a household with two other children were less likely to be living with obesity (Figure 3; uni- and multi-variable results are presented in Table S4).

In multivariable linear regression, a one unit increase in the oldest child's BMI z-score was associated with a 0.32 (95% CI: 0.30,0.33) increase in the index child's BMI z-score. Similarly, in linear regression models stratified by the school year of participation in the NCMP, a one unit increase in the oldest child's BMI z-score predicted a 0.28 (0.27,0.29) and 0.38 (0.35,0.40) increase in Reception and Year 6 index child's BMI z-scores, respectively.

Discussion

Summary of key findings

We examined associations between child household weight status using novel linkages between school measurement and EHRs. We showed that younger children living with an older child with obesity were more than four times more likely to live with obesity than those living with an older child with a healthy weight.

Strengths and limitations

We used ethnic-specific BMI adjustments and the UK1990 clinical thresholds to identify children with obesity considered in need of clinical intervention in an ethnically-diverse area of London with high levels of childhood obesity.

We used linked NCMP records of weight status as we have previously shown that GP EHRs do not contain accurate, up-to-date child measurement data and are biased to children at both extremes of the BMI distribution.⁽²⁴⁾ This resulted in exclusion of 30,552 NCMP participants who did not live with another NCMP participant in the 2013-2019 academic years.

We used a robust methodology to identify household members at the time of the NCMP measurement. The ASSIGN algorithm has been shown to match 98.6% of primary care patient addresses to UPRNs.⁽¹⁸⁾ We adopted a conservative approach to identify “true” household members, by excluding NCMP participants living in large or non-residential households. It is possible that we included patients who no longer live at their registered address (so would not consult with their registered GP). There is also likely to be a time lag between a patients’ GP registrations, and a period of time where a patient has moved on from an area but remains registered with a GP. Hence, we may have overestimated the true number of household members.

We were not able to determine whether child household members were biologically related. Similarly, we were not able to identify biological parents and account for parental BMI in our analyses. To our knowledge, this is the first time that other children in the household (as opposed to biologically-related siblings) have been accounted for in analyses of childhood obesity. Children are increasingly living in blended families including household members with no biological relationship. Multi-family households (consisting of two or more families) were the fastest growing household type in the UK between 1999 and 2019.⁽²⁵⁾

Comparison with existing literature

Our findings support those reporting an increased likelihood of obesity among children living with other children with obesity.(12, 14) Children in the same household spend their time together and share the same resources, which supports the notion of the 'shared home environment'.(26) Siblings eat similar diets, and participate in similar levels of physical activity and sedentary behaviours.(14) Others note that older children are important influencers in children's health-related behaviours, particularly healthy eating. Younger children want to copy the behaviours of their older siblings, explaining the positive correlation between both children's healthy and unhealthy behaviours.(27, 28)

Implications for research, policy and practice

Our findings highlight the importance of taking a household perspective in tackling childhood obesity. A household-level approach may potentially reach more children living with, and at risk of, obesity, to encompass a broader range of factors which may or may not influence obesity among all resident children.

Routinely collected EHRs provide a limited view of the home environment, and further qualitative research is necessary to fully understand who the decision-makers are, and how practices and attitudes relating to food purchasing and diet, as well as physical activity opportunities, are negotiated on a daily basis.

Conclusion

Children living with an older child with obesity are more likely to be living with obesity. Early intervention should be approached from a household perspective which takes into account the roles of, and implications for, all household members.

Funding

This work was supported by ADR UK (Administrative Data Research UK), an Economic and Social Research Council investment (part of UK Research and Innovation) [Grant number: ES/X00046X/1]. This research was also supported by a grant from Barts Charity ref: MGU0419. ¹ National Child Measurement Programme (NCMP)-recorded body mass index (BMI) after application of ethnic-specific BMI adjustments, categorised according to UK1990 clinical reference standard: "underweight or healthy weight" (<91st centile), "overweight" (≥91st to <98th centile), or "obese" (≥98th centile). ² Confidence interval. ³ School year of participation in the NCMP, Reception participants are aged 4-5 years and Year 6 participants are aged 10-11 years. ⁴ Academic year of participation in the National Child Measurement Programme (NCMP). Academic years run from September to July. The 2013/14 and 2014/15 academic years were combined to minimise the risk of disclosing individuals. ⁵ Local authority of school where child participated in the NCMP. ⁶ As recorded in the NCMP and, where missing, supplemented with ethnic background as recorded in the child's primary care electronic health record.

Figure titles and footnotes

Figure 1 – Identifying a valid Residential Anonymised Linkage Field (RALF) at the time of National Child Measurement Programme (NCMP) measurement

Children living in non-residential dwellings or where the UPRN match qualifier was not a “best” residential match were excluded (n=3,903). The match qualifier indicates how close to the place of residence the assigned UPRN is.

Figure 2 – Oldest child’s weight status stratified by index child’s weight status¹

¹ *National Child Measurement Programme (NCMP)-recorded body mass index (BMI) after application of ethnic-specific BMI adjustments, categorised according to UK1990 clinical reference standard: “underweight or healthy weight” (<91st centile), “overweight” (≥91st to <98th centile), or “obese” (≥98th centile).*

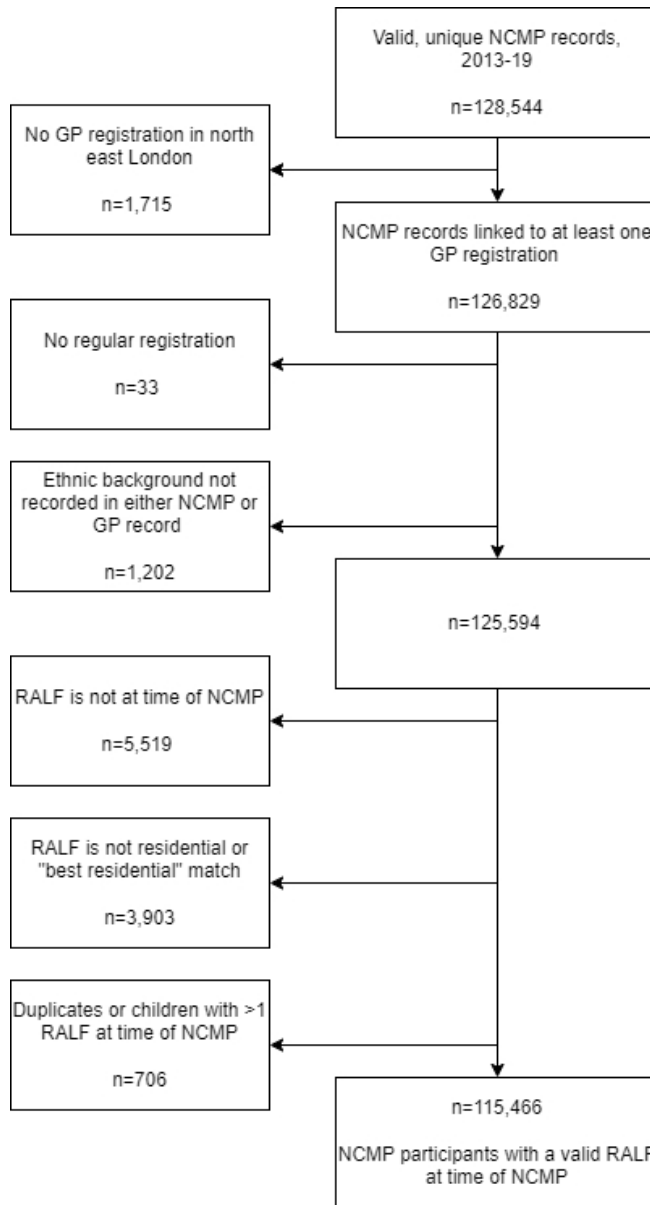

Figure 3 – Multivariable¹ odds ratio estimating the likelihood of obesity² among the youngest children living in households with two National Child Measurement Programme participants

¹ *The model including all households with two National Child Measurement Programme (NCMP) participants mutually adjusted for oldest child’s weight status, number of children in the household, sex, ethnic background as recorded in the NCMP and, where missing, supplemented with ethnic background as recorded in the child’s primary care electronic health record, school year of participation in the NCMP (Reception participants are aged 4-5 years and Year 6 participants are aged 10-11 years) and local authority of school where child participated in the NCMP. The model which only included households where the youngest child participated in the NCMP in Reception year mutually adjusted for the oldest child’s weight status, number of children in the household, sex and ethnic background. The model which only included households where the youngest child participated in the NCMP in Year 6 mutually adjusted for the oldest child’s weight status, sex and ethnic background. ² NCMP-recorded body mass index (BMI) after application of ethnic-specific BMI adjustments, categorised according to UK1990 clinical reference standard: “obese” (≥98th centile). ³ Odds ratio and confidence interval. Odds ratios are plotted on a logarithmic scale.*

Figure S2 – Identifying National Child Measurement Programme (NCMP) participants' valid General Practice (GP)-recorded Residential Anonymised Linkage Fields (RALFs)

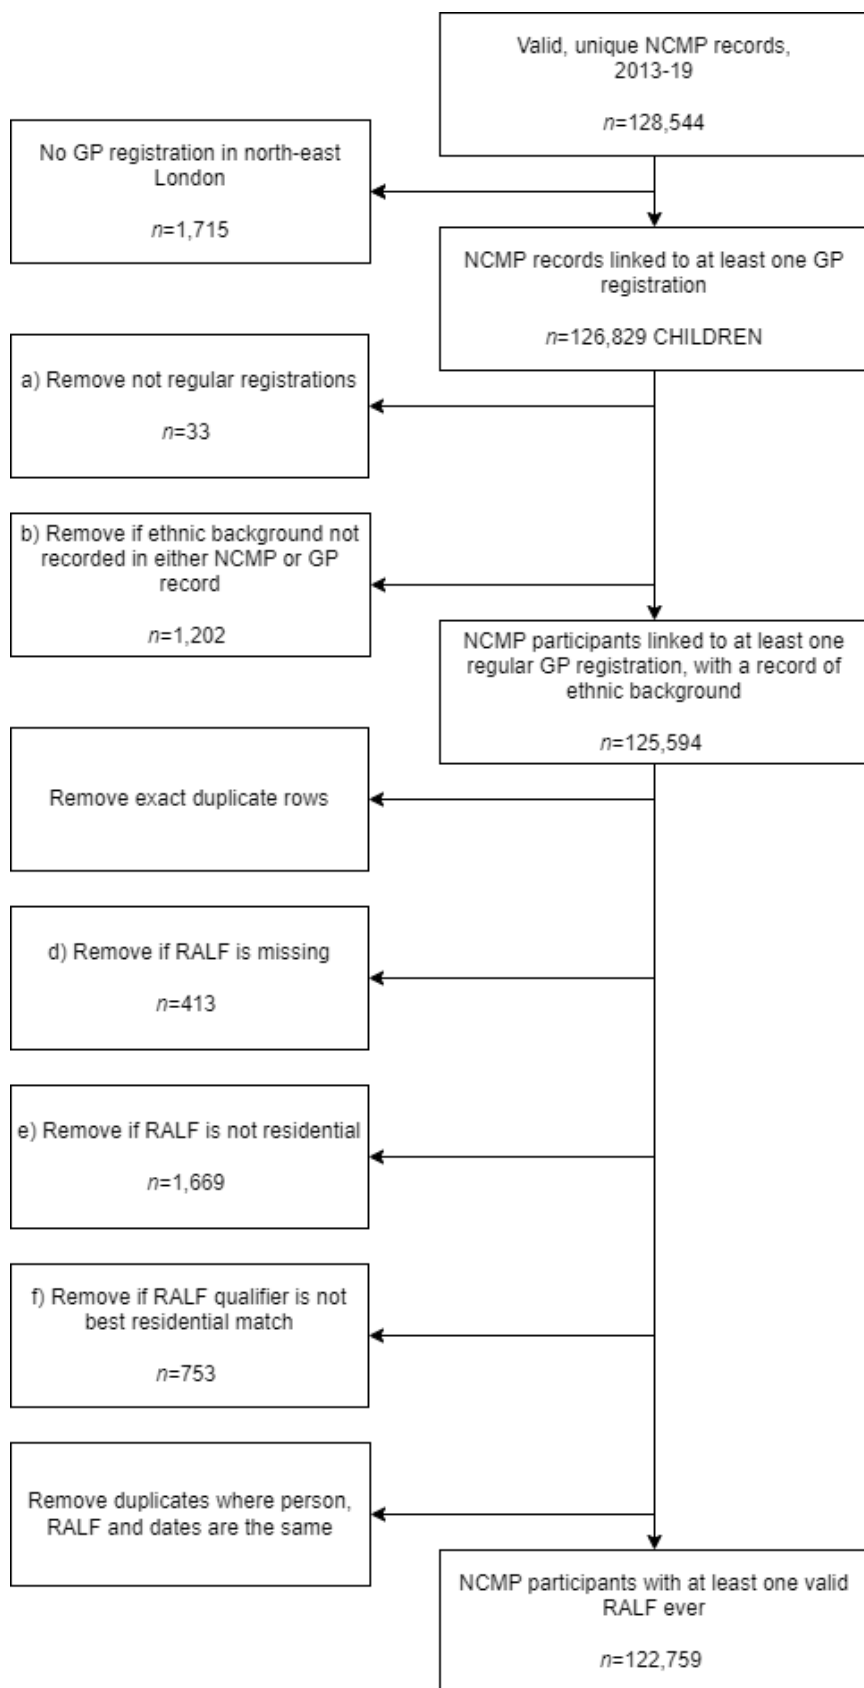

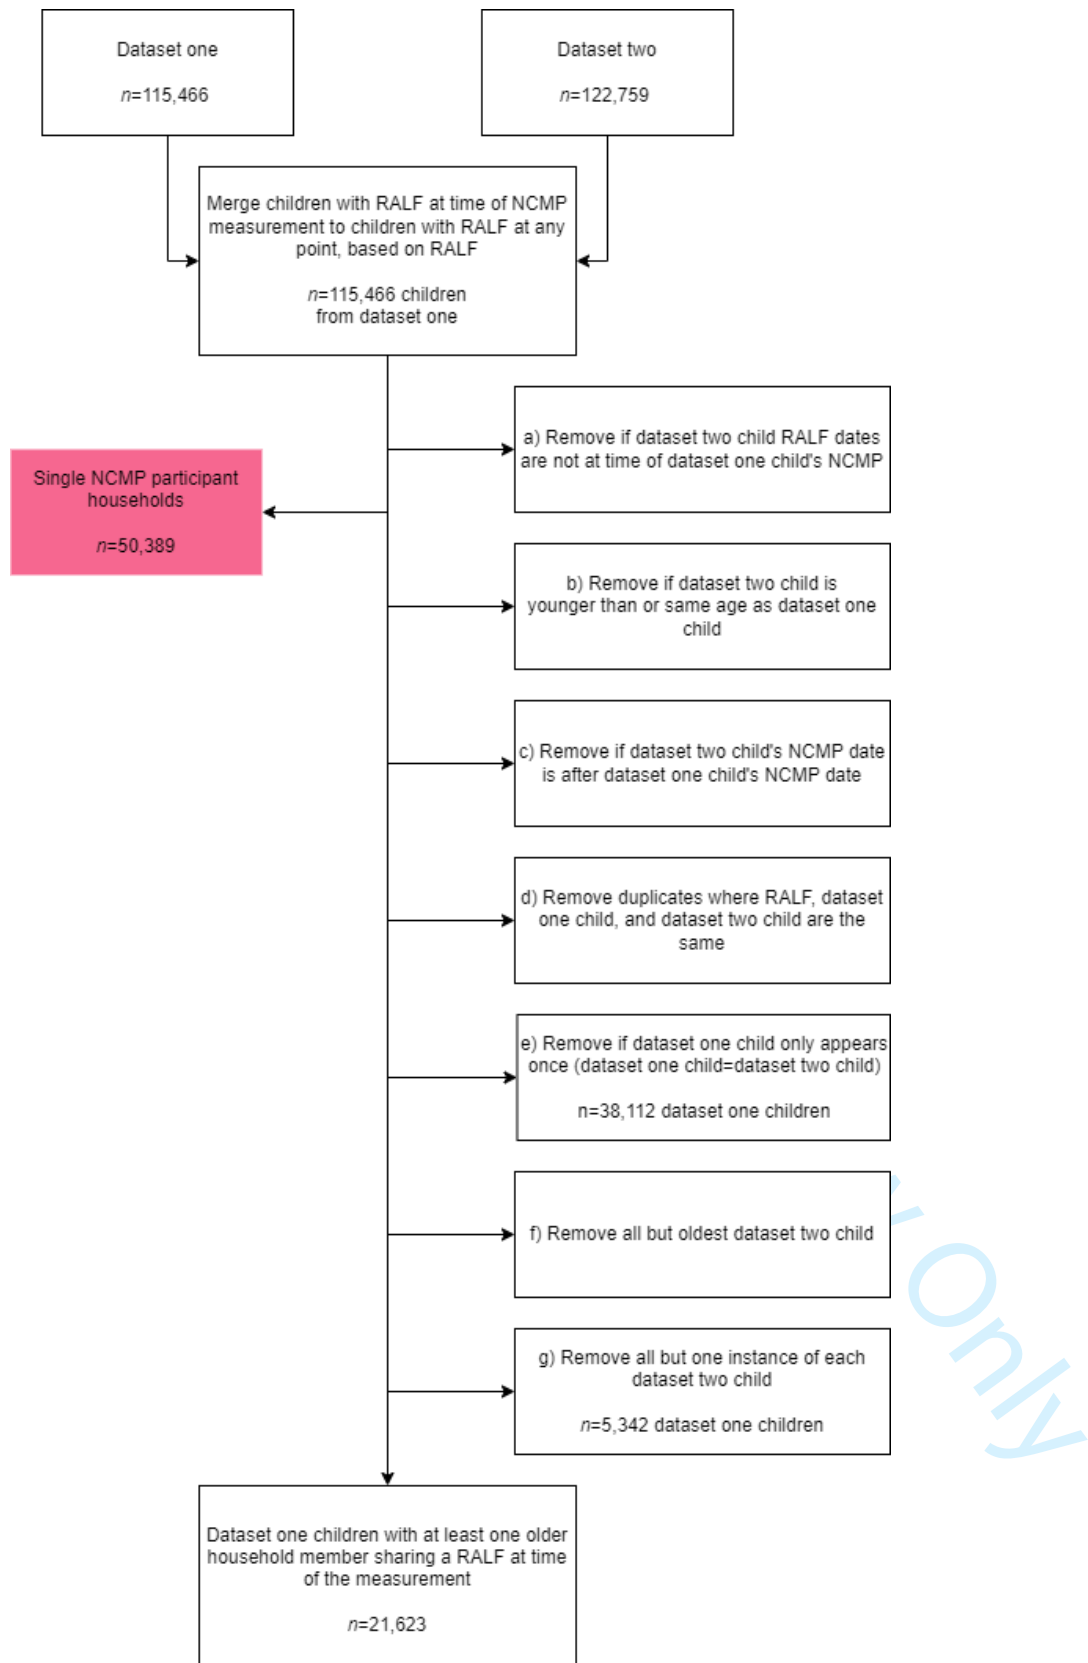

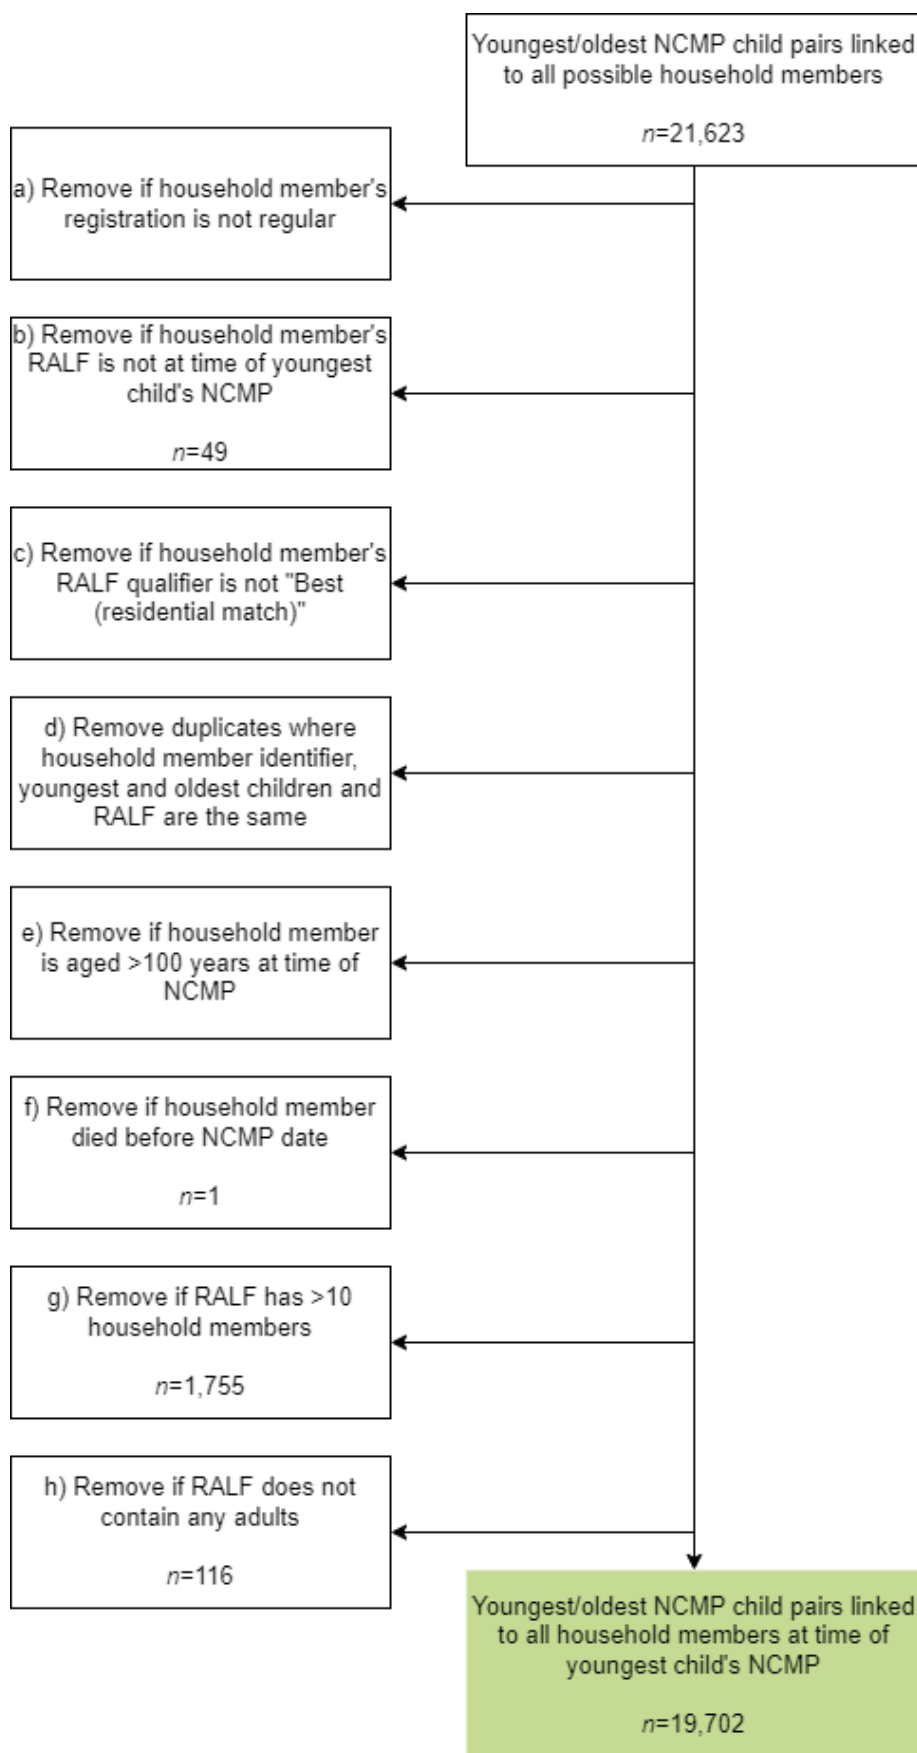

Figure S3 – Identifying National Child Measurement Programme (NCMP) participants sharing a household using Residential Anonymised Linkage Fields (RALFs)

Index children were joined with children in dataset two using Stata's many to many `joinby` function, combining all pairwise combinations on common RALFs. Where an older child matched to multiple index children, only one random pair was retained (n=5,342).

Figure S4 – Identifying all other household members at the time of the index child's NCMP measurement

For each household member, age at the time of the youngest child's NCMP measurement was calculated.

Table S1 – Sample characteristics of oldest National Child Measurement Programme participants in the household

The distribution by sex, ethnic background and weight status was broadly representative of NCMP participants in the four local authorities as a whole.

26 Abstract

27 Background/objectives

28 We identified household members from electronic health records linked to National Child Measurement
29 Programme (NCMP) data to estimate the likelihood of obesity among children living with an older child with
30 obesity.
31

32 Methods

33 We included 126,829 NCMP participants in four London boroughs and assigned households from encrypted
34 Unique Property Reference Numbers for 115,466 (91.0%). We categorised the ethnic-adjusted body mass
35 index of the youngest and oldest household children (underweight/healthy weight < 91st, ≥ 91st overweight < 98th,
36 obesity ≥ 98th centile) and estimated adjusted odds ratios (OR) and 95% confidence intervals (CI) of obesity in
37 the youngest child by the oldest child's weight status, adjusting for number of household children (two, three
38 or ≥ 4), youngest child's sex, ethnicity, and school year of NCMP participation.
39
40
41
42

43 Results

44 We identified 19,702 households shared by two or more NCMP participants (% male; median age, range
45 (years), youngest children: 51.2%; 5.2, 4.1-11.8; oldest children: 50.6%; 10.6, 4.1-11.8). One third of youngest
46 children with obesity shared a household with another child with obesity (33.2%; 95% CI: 31.2, 35.2), compared
47 with 9.2% (8.8, 9.7) of youngest children with a healthy weight. Youngest children living with an older child
48 considered overweight (OR: 2.33; 95% CI: 2.06, 2.64) or obese (4.59, 4.10, 5.14) were more likely to be living
49 with obesity.
50
51

52 Conclusions

53 Identifying children sharing households by linking primary care and school records provides novel insights into
54 the shared weight status of children sharing a household. Qualitative research is needed to understand how
55 food practices vary by household characteristics to increase understanding of how the home environment
56 influences childhood obesity.

Key words

Childhood, obesity, households, BMI, electronic health records, record linkage

Key messages

There is evidence to suggest that children living with older siblings with obesity are more likely to be living with obesity themselves. Research to date has largely focused on the weight status of biological siblings .

What this study adds

We examined associations between child household weight status using novel linkages between school measurement and electronic health records. We showed that younger children living with an older child with obesity were more than four times more likely to live with obesity than those living with an older child with a healthy weight.

How this study might affect research, practice or policy

Household factors are potentially more modifiable than genetic or prenatal influences. Taking a household-level approach could potentially reach more children living with, and at risk of, obesity.

Introduction

Childhood obesity is a major public health concern globally and reflects a complex number of factors, in particular socio-economic inequalities.(1) In England, more than one quarter of children leave primary school with overweight or obesity at a level of severity defined as in need of clinical intervention.(2)

A child's health, including their weight status, is significantly affected by the environment in which they live. Better understanding of households, their composition, and the health of children and adults who share households may provide novel actionable insights to address unhealthy weight in childhood.

Research has shown that child obesity is associated with parental obesity, where parental overweight or obesity is associated with an increased risk of obesity in their child.(3) This relationship is stronger for mothers than fathers.(4, 5) Less is known about the associations between the obesity status of child household members. Research investigating associations between siblings' weight status has reported inconsistent results.(6-13) Children living together may experience similar genetic, environmental, and socioeconomic circumstances, which may in turn contribute to a shared risk for obesity. The shared household environment is potentially more modifiable than genetic or prenatal influences.

A 2023 systematic review identified that siblings' health-related behaviours and weight-related outcomes varied according to sibling sex and birth order.(14) Our understanding of how household composition, including presence of a sibling or other household children, as well as their weight status, influences childhood obesity could be improved with further research which includes all child household members and not just those who are biologically-related.

We identified individuals sharing a household using electronic health records and linked this to school measurement programme data to estimate the likelihood of obesity among children living with an older child with obesity. We hypothesised that younger children will be more likely to be living with obesity if they share a household with an older child living with obesity. We also investigated whether household composition and size, and dwelling type, influenced the likelihood of childhood obesity.

Methods

Study population

Children in the first (Reception year) and last (Year 6) years of primary school are invited to participate in the National Child Measurement Programme (henceforth known as the school measurement programme), which measures the height and weight of 4-5- and 10-11-year-olds attending state-maintained schools in England. More than one million children take part annually, with participation rates remaining higher than 90% since 2010/11.(15) School participation is voluntary, although over 99% participate.(16) In City & Hackney, approximately one quarter of school-aged children attend private or faith schools, compared with equivalent figures of 1.4%, 5.0% and 5.0% for Newham, Tower Hamlets, and Waltham Forest, respectively.(17) We do not have information about the small proportion of children who opt out of the school measurement programme. We linked 126,829 of 128,544 (98.7%) school measurement programme records from four north-east London local authorities (City & Hackney, Newham, Tower Hamlets, and Waltham Forest) to general practice (GP) electronic health records via the Discovery Data Service.(18)

Data sources

We obtained pseudonymised school measurement programme data for the 2013/14-2018/19 academic years under data processing agreements with each local authority public health department. We only received school measurement programme records that had been returned to each local authority after quality assurance checks.(19) As the available date of school measurement programme measurement was restricted to month and year, we randomly assigned a day of measurement within term-time, excluding weekends and bank holidays to avoid a spurious reduction in variance in age at measurement occasioned by using the same fixed date of measurement for every child (R Studio; version 1.0.153; code available here: bit.ly/random_day).

Pseudonymised data were provided from the Discovery Data Service which receives primary care electronic health records on a daily basis from all GPs in north-east London. Demographic and clinical data recorded up to 1st November 2021 were extracted for school measurement programme participants successfully linked to the Discovery Data Service via pseudonymised NHS numbers created using OpenPseudonymiser software.(20)

1
2
3 All data were extracted and managed according to UK National Health Service (NHS) information governance
4 requirements.(21)

8 *Residential Anonymised Linkage Fields*

9
10
11
12
13
14 Every addressable location in Great Britain is assigned a Unique Property Reference Number (UPRN). UPRNs
15 identify a place of residence at a granular level, identifying individual properties, for example houses or flats
16 within a block or building shell. UPRNs are allocated to GP-recorded addresses using the validated ASSIGN
17 algorithm,(22) and pseudonymised into Residential Anonymised Linkage Fields (RALFs) within the Discovery
18 Data Service, using a study-specific encryption key.
19
20
21
22
23

24 *Identifying household members at the child's school measurement date*

25
26
27
28 A household can only be defined at a single point in time because people living at an address may change over
29 time whilst the UPRN assigned to the residential dwelling stays the same.
30
31

32
33 A data extract containing all RALFs associated with any address(es) recorded in a child's electronic health
34 record was extracted. The file contained start and end dates of patient registration (enrolment) with the GP as
35 well as address start and end dates. Address start and end dates refer to the dates at which a patient lived at a
36 particular address. In most cases, these align with GP registration dates, but could differ, if for example, a
37 patient moved house but remained registered with the same GP.
38
39
40
41
42

43
44 Figure 1 describes the process for deciding which, if any, of the child's RALFs was the place of residence at the
45 time of their school measurement programme measurement. If the school measurement programme date of
46 measurement took place between the most recent of the registration and address start dates and the earliest
47 of the registration and address end dates, the RALF was considered to be the place of residence at the time of
48 school measurement programme (supplementary Figure S1). Children without a RALF at the time of their
49 school measurement programme were excluded ($n=5,519$). We retained 115,466 children with a RALF at the
50 time of their school measurement programme measurement (referred to hereafter as index children).

Identifying other National Child Measurement Programme participants in the household

Similar steps were taken to identify other school measurement programme participants sharing a household with index children. We started with 122,759 school measurement programme participants with at least one RALF (supplementary Figure S2) and included in “dataset two”.

Child pairs were excluded if the index child’s school measurement programme measurement date did not fall within dataset two child’s RALF dates (supplementary Figure S3). Pairs were also excluded if the dataset two child was younger than the index child or if the dataset two child’s school measurement programme measurement was after the index child’s. This process found the youngest index child and identified the oldest school measurement programme participant living in the same household at the time of the index child’s school measurement programme measurement. Of 128,554 school measurement programme participants, 21,623 youngest/oldest child pairs were identified.

Identifying other household members and deriving household characteristics

We identified all people who had ever lived at any of the RALFs identified in the dataset of youngest/oldest child pairs. Steps were taken to determine household members at the time of the index child’s school measurement programme measurement (supplementary Figure S4). Full household information was identified for 19,702 youngest/oldest child pairs.

Outcome of interest

Obesity status of the index child was defined by the UK1990 clinical reference standard.(23) After application of ethnic-specific BMI adjustments,(24) a binary variable indicating obesity was defined as a BMI greater than or equal to the 98th age- and sex-specific centile. The index child’s ethnic-adjusted BMI z-score was a secondary outcome.

Explanatory variables

Ethnic-specific BMI adjustments(24) were applied to the older child’s BMI, and weight status determined according to the UK1990 clinical reference standard(23) categorising BMI into one of four mutually exclusive groups: “underweight” (<2nd centile), “healthy weight” (≥2nd to <91st centile), “overweight” (≥91st to <98th

1
2
3 centile) or “obese” (≥ 98 th centile). The older child’s BMI z-score was also considered as an explanatory
4
5 variable.

8 School measurement programme -recorded sex, local authority of the school where the child participated in
9
10 the school measurement programme, academic year (September to July) and school year (Reception/Year 6)
11
12 of participation in the school measurement programme were explanatory variables.

13
14 School measurement programme -recorded ethnic background was grouped into four mutually exclusive
15
16 groups(25): White (‘White British’, ‘White Irish’, or ‘any other White background’); Black (‘Black African’, ‘Black
17
18 Caribbean’, or ‘any other Black background’); South Asian (‘Indian’, ‘Pakistani’, ‘Bangladeshi’ or ‘Sri Lankan’);
19
20 and a combination of Mixed and Other (‘any other ethnic background’, ‘mixed ethnicity’, ‘Chinese’ or ‘Asian
21
22 other’). Where ethnic background was missing or not stated in the school measurement programme, ethnic
23
24 background as recorded in the electronic health record ($n=11,077$) was used.

25
26
27 An area-level measure of relative deprivation - Index of Multiple Deprivation (IMD) decile(26) - was assigned to
28
29 each school measurement programme record based on the postcode of the child’s home address. IMD decile
30
31 was concatenated into five quintiles ranging from most to least deprived.

32
33
34 A categorical variable was derived from a count of children (aged <18.0 years) assigned the same RALF as the
35
36 school measurement programme participant, grouped as follows: 2; 3-4; 5-6; 7-10.

37
38
39 We categorised household composition using a modified Harper and Mayhew method(27) by counting the
40
41 number of household members in three age brackets: 0-17 years (children), 18-64 years (working age adults)
42
43 and 65 or older (older adults) and grouping into: working-aged adults with children; a single working-age adult
44
45 with children; at least one working-age and one older adult with children (three generation household), or at
46
47 least one older adult with children (skipped generation household).

48
49
50 The property classification, as given by the ASSIGN algorithm, categorised properties into three groups: flats,
51
52 terraced houses, and other.

53
54
55 Sex concordance was coded either the same (when both children shared the same sex) or different (when the
56
57 two children had differing sexes). The time difference between the youngest and oldest children’s school
58
59
60

1
2
3 measurement programme measurements was calculated as the time in months between the two
4
5 measurements.
6
7

8 **Statistical analyses**

9
10 We estimated the prevalence of obesity among children living with an older school measurement programme
11 participant and explored variation by the weight status of the older child. We used binary logistic regression to
12 estimate the likelihood of obesity in the index child (odds ratio [OR] and 95% confidence interval [CI]) by the
13 older child's weight status, after accounting for individual and household characteristics. We conducted linear
14 regression to estimate the effect of a one unit increase in the oldest child's BMI z-score on the index child's
15 BMI z-score, after checking residuals were normally distributed. All analyses, conducted using Stata (MP/15.0),
16 were stratified by school year.
17
18
19
20
21
22
23
24

25 **Patient and public involvement**

26
27
28 This research was done without patient or public involvement. Neither were invited to comment on the study
29 design and were not consulted to develop relevant outcomes or interpret results.
30
31
32

33 **Ethics approval**

34
35 The analyses of linked pseudonymised school measurement programme and GP data were approved by the
36 respective data controllers under data processing agreements which allow linkage of pseudonymised school
37 measurement programme data between the research organisation and each local authority public health
38 team. This study is a secondary analysis of de-identifiable data and no further ethics approval was required.
39
40
41
42
43
44

45 **Results**

46
47
48 Index children were, by study design, more likely to take part in the school measurement programme in the
49 Reception school year and in the more recent academic years (Table 1). Similarly, the oldest children were
50 more likely to take part in the school measurement programme in Year 6 and in the earlier academic years
51 (supplementary Table S1). 7.9% of Reception year youngest children and 16.3% of Year 6 youngest children
52 were living with obesity (Table 1). Equivalent estimates using International Obesity Task Force cut-offs are
53
54
55
56
57
58
59
60

1
2
3 reported in supplementary Table S2. Three quarters lived in households with adults of working age only, and
4
5 more than half lived in flats (Table 2).
6

7
8 A greater proportion of index children with obesity were male, participating in the school measurement
9
10 programme in Year 6 and in Tower Hamlets and Newham, and from South Asian ethnic backgrounds,
11
12 compared with index children with underweight or a healthy weight (Table 3).
13

14
15 There was no variation in the number of children sharing a household or property classification by weight
16
17 status (Table S3). A lower proportion of index children living with obesity lived in households with a single
18
19 adult (12.5%; 95% CI: 11.2,14.0) compared with the proportion among children with an underweight/healthy
20
21 weight status (14.9%; 14.4,15.5).
22

23
24 One fifth and one third of index children living with obesity shared a household with another child with
25
26 overweight or obesity, respectively, higher than those with underweight or of a healthy weight (Table S4;
27
28 Figure 2). Sex concordance, nor time difference between the index and older children's school measurement
29
30 programme measurement dates, did not vary by weight status of the index child.
31

32
33 In adjusted analyses, index children living with an older child with overweight or obesity were more likely to be
34
35 living with obesity. Conversely, those sharing a household with two other children were less likely to be living
36
37 with obesity (Figure 3; uni- and multi-variable results are presented in Table S5).
38

39
40 In multivariable linear regression, a one unit increase in the oldest child's BMI z-score was associated with a
41
42 0.32 (95% CI: 0.30,0.33) increase in the index child's BMI z-score. Similarly, in linear regression models
43
44 stratified by the school year of participation in the school measurement programme, a one unit increase in the
45
46 oldest child's BMI z-score predicted a 0.28 (0.27,0.29) and 0.38 (0.35,0.40) increase in Reception and Year 6
47
48 index child's BMI z-scores, respectively.
49

50 Discussion

51 Summary of key findings

52
53
54
55
56 We examined associations between child household weight status using novel linkages between school
57
58 measurement and electronic health records. We showed that younger children living with an older child with
59
60

1
2
3 obesity were more than four times more likely to live with obesity than those living with an older child with a
4
5 healthy weight.
6
7

8 **Strengths and limitations**

9
10 We used UK1990 clinical thresholds to identify children with obesity considered in need of clinical
11
12 intervention, as advised by the Scientific Advisory Committee on Nutrition,(23) in an ethnically-diverse area of
13
14 London with high levels of childhood obesity. We recognise these cut-offs do not allow for international
15
16 comparisons. Our findings may not be generalisable to areas in the UK with lower levels of deprivation and
17
18 ethnic diversity. The school measurement programme has high participation rates, but our study sample did
19
20 not include children attending non-state maintained schools of which there is a higher proportion in City &
21
22 Hackney.
23

24
25 We used linked school measurement programme records of weight status as we have previously shown that
26
27 GP electronic health records do not contain accurate, up-to-date child measurement data and are biased to
28
29 children at both extremes of the BMI distribution.(28) This resulted in exclusion of 30,552 school measurement
30
31 programme participants who did not live with another school measurement programme participant in the
32
33 2013-2019 academic years.
34

35
36 We used a robust methodology to identify household members at the time of the school measurement
37
38 programme measurement. The ASSIGN algorithm has been shown to match 98.6% of primary care patient
39
40 addresses to UPRNs.(22) We adopted a conservative approach to identify “true” household members, by
41
42 excluding school measurement programme participants living in large or non-residential households. It is
43
44 possible that we included patients who no longer live at their registered address (so would not consult with
45
46 their registered GP). There is also likely to be a time lag between a patients’ GP registrations, and a period of
47
48 time where a patient has moved on from an area but remains registered with a GP. Hence, we may have
49
50 overestimated the true number of household members.
51

52
53 We were not able to determine whether child household members were biologically related. Similarly, we
54
55 were not able to identify biological parents and account for parental BMI in our analyses.
56

57 **Comparison with existing literature**

1
2
3 Our findings support those reporting an increased likelihood of obesity among children living with other
4 children with obesity.(12, 14) There are likely to be several explanations for this. Firstly, children in the same
5 household spend their time together and share the same resources, which supports the notion of the 'shared
6 home environment'.(29) Siblings eat similar diets, and participate in similar levels of physical activity and
7 sedentary behaviours.(14) Others note that older children are important influencers in children's health-
8 related behaviours, particularly healthy eating. Younger children want to copy the behaviours of their older
9 siblings, explaining the positive correlation between both children's healthy and unhealthy behaviours.(30, 31)
10 Children living in the same household are likely to be exposed to the same level of family income, and
11 potentially the same diet and physical activity.(32) Outside of the home, children will be exposed to the same
12 built environment. Finally, biologically related children sharing the same household may share a common
13 genetic predisposition to obesity.(33)

24 **Implications for research, policy and practice**

25
26 Our findings highlight the importance of understanding the household distribution of childhood obesity when
27 designing services in populations with high prevalences of obesity and limited resources. A household-level
28 approach may be a pragmatic response to identifying higher risk households by considering information about
29 all resident children. The shared household environment is potentially more modifiable than genetic or
30 prenatal influences, and analyses of the shared weight status of household members provides new insights
31 about people sharing the same living space, regardless of their biological relationships. This insight is
32 particularly pertinent now that children are increasingly living with household members with whom they may
33 have no biological relationship.(34)

34
35 Routinely collected electronic health records provide a limited view of the home environment, and further
36 qualitative research is necessary to fully understand who the decision-makers are, and how practices and
37 attitudes relating to food purchasing and diet, as well as physical activity opportunities, are negotiated on a
38 daily basis.

1
2
3 **Conclusion**
4
5
6

7 Children living with an older child with obesity are more likely to be living with obesity. Early intervention
8 should be approached from a household perspective which takes into account the roles of, and implications
9 for, all household members.

Confidential: For Review Only

Funding

This work was supported by ADR UK (Administrative Data Research UK), an Economic and Social Research Council investment (part of UK Research and Innovation) [Grant number: ES/X00046X/1]. This research was also supported by grants from Barts Charity ref: MGU0419 and MGU0504. This work was supported by the UK Prevention Research Partnership (MR/S037527/1), which is funded by the British Heart Foundation, Cancer Research UK, Chief Scientist Office of the Scottish Government Health and Social Care Directorates, Engineering and Physical Sciences Research Council, Economic and Social Research Council, Health and Social Care Research and Development Division (Welsh Government), Medical Research Council, National Institute for Health Research, Natural Environment Research Council, Public Health Agency (Northern Ireland), The Health Foundation and Wellcome.

Competing interests

The authors declare no competing financial interests.

Author contributions

CD obtained funding for the study. NF, CD and GH conceptualised and designed the analyses. NF, MW, MM, GH and CD contributed to the development of the methodology. NF carried out the literature search, conducted the analyses, generated tables and figures and drafted the initial manuscript. NF, MW, MM, GH, LG, and CD contributed to the interpretation of analyses and reviewed and revised the manuscript. NF, MW, MM, GH, LG, and CD were involved in writing the paper and had final approval of the submitted and published manuscript. The corresponding author attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

Data sharing

Access to primary care data is enabled by data sharing agreements between the Discovery Data Service and the data controllers. The Discovery Programme Board has approved data access by the REAL Child Health programme team for research on the condition that it is not onwardly shared. National Child Measurement Programme data were accessed under data processing agreements with each of the local authorities as data controllers in line with Public Health England guidance. These agreements preclude onward sharing of data.

Acknowledgements

The authors are grateful to the local authority public health teams for providing pseudonymised National Child Measurement Programme data, school nurses and National Child Measurement Programme data collection teams, and National Child Measurement Programme participants. We are grateful to Professor Mario Cortina-Borja (University College London Great Ormond Street Institute of Child Health) for supporting the development of an algorithm to randomly assign a day of measurement. We are grateful to the data controllers of the Discovery Programme and to the GPs and their practice teams for allowing the use of their patient records, to the Clinical Effectiveness Group for providing access to their curated high-quality dataset, and to the population in east London from whom the data are derived. This work uses data provided by patients and collected by the NHS as part of their care and support.

Terraced house	8154	41.4	40.7,42.1
Other	1288	6.5	6.2,6.9

¹ Confidence interval. ² 2015 Index of Multiple Deprivation (IMD) quintile assigned based on the child's home address postcode as recorded by the school where the child participated in the National Child Measurement Programme. The 2015 IMD accounts for socioeconomic characteristics in lower layer super output areas (LSOAs), small geographies typically comprising an average population of 1,500 people or 650 households. IMD score is derived from Indices of Deprivation, which cover seven domains: income; employment; education, skills and training; health; crime; barriers to housing and services; and living environment. The IMD score for each LSOA in England is ranked, from most to least deprived, and divided into ten equal groups indicating the most deprived 10% of LSOAs to the least deprived 10% of LSOAs, nationally. The school measurement programme dataset includes each child's IMD 2015 score and decile.

Figure titles and footnotes

Figure 1 – Identifying a valid Residential Anonymised Linkage Field (RALF) at the time of National Child Measurement Programme (NCMP) measurement

Children living in non-residential dwellings or where the UPRN match qualifier was not a “best” residential match were excluded (n=3,903). The match qualifier indicates how close to the place of residence the assigned UPRN is. We excluded 3,903 without residential Residential Anonymised Linkage Field (RALF) or best match RALF qualifier. In most cases (66.8%), the RALF assigned to these GP-recorded addresses was associated with a property shell, rather than the exact individual property. Others were living in sheltered accommodation or houses of multiple occupancy not further divided to enable household identification. The prevalence of overweight and obesity among the excluded children was similar to estimates among index children.

Figure 2 – Oldest child’s weight status stratified by index child’s weight status¹

¹ *National Child Measurement Programme (NCMP)-recorded body mass index (BMI) after application of ethnic-specific BMI adjustments, categorised according to UK1990 clinical reference standard: “underweight or healthy weight” (<91st centile), “overweight” (≥91st to <98th centile), or “obese” (≥98th centile).*

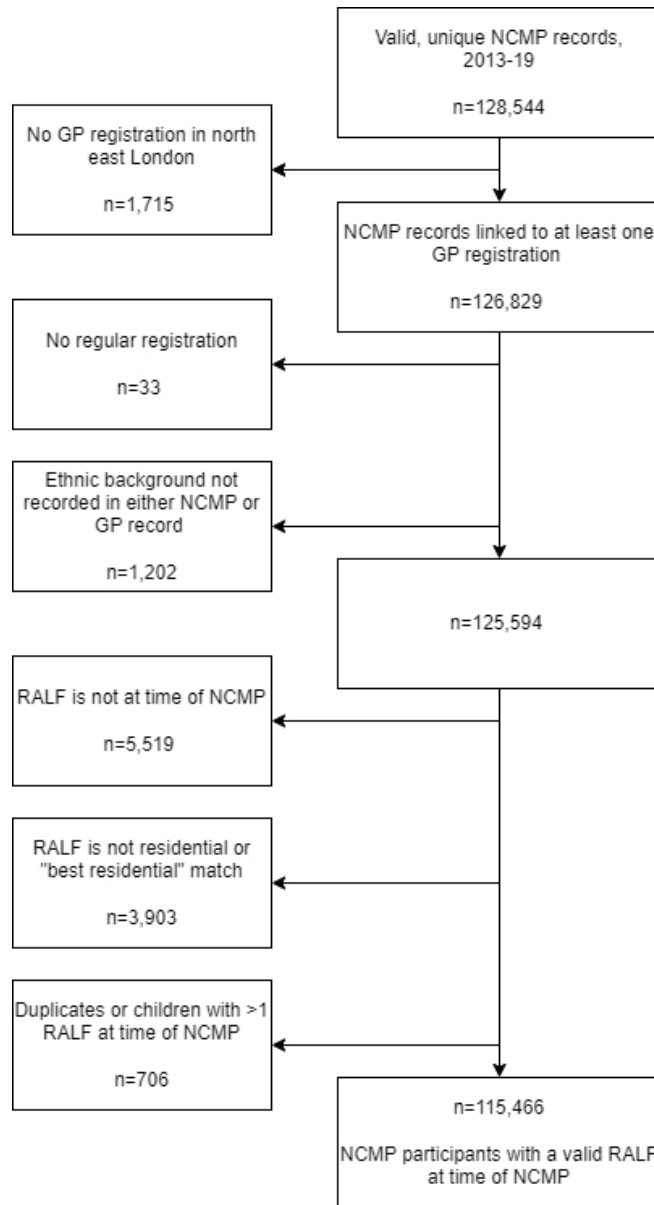

Figure 3 – Multivariable¹ odds ratio estimating the likelihood of obesity² among the youngest children living in households with two National Child Measurement Programme participants

¹ *The model including all households with two National Child Measurement Programme (NCMP) participants mutually adjusted for oldest child’s weight status, number of children in the household, sex, ethnic background as recorded in the NCMP and, where missing, supplemented with ethnic background as recorded in the child’s primary care electronic health record, school year of participation in the NCMP (Reception participants are aged 4-5 years and Year 6 participants are aged 10-11 years) and local authority of school where child participated in the NCMP. The model which only included households where the youngest child participated in the NCMP in Reception year mutually adjusted for the oldest child’s weight status, number of children in the household, sex and ethnic background. The model which only included households where the youngest child participated in the NCMP in Year 6 mutually adjusted for the oldest child’s weight status, sex and ethnic background. ² NCMP-recorded body mass index (BMI) after application of ethnic-specific BMI adjustments, categorised according to UK1990 clinical reference standard: “obese” (≥98th centile). ³ Odds ratio and confidence interval. Odds ratios are plotted on a logarithmic scale.*

View Only

Figure S3 – Identifying National Child Measurement Programme (NCMP) participants sharing a household using Residential Anonymised Linkage Fields (RALFs)

Index children were joined with children in dataset two using Stata's many to many `joinby` function, combining all pairwise combinations on common RALFs. Where an older child matched to multiple index children, only one random pair was retained ($n=5,342$).

Figure S4 – Identifying all other household members at the time of the index child’s NCMP measurement

For each household member, age at the time of the youngest child's NCMP measurement was calculated.

Table S1 – Sample characteristics of oldest National Child Measurement Programme participants in the household

The distribution by sex, ethnic background and weight status was broadly representative of NCMP participants in the four local authorities as a whole.

¹ National Child Measurement Programme (NCMP)-recorded body mass index (BMI) after application of ethnic-specific BMI adjustments, categorised according to UK1990 clinical reference standard: "obese" (≥98th centile). ² Mutually adjusting for oldest child's weight status, number of children in the household, sex, ethnic background and school year. ³ Mutually adjusting for the oldest child's weight status, number of children in the household, sex and ethnic background. ⁴ Mutually adjusting for the oldest child's weight status, sex and ethnic background. ⁵ Odds ratio. ⁶ Confidence interval. ⁷ National Child Measurement Programme (NCMP)-recorded body mass index (BMI) after application of ethnic-specific BMI adjustments, categorised according to UK1990 clinical reference standard: "underweight or healthy weight" (<91st centile), "overweight" (≥91st to <98th centile), or "obese" (≥98th centile). ⁸ As recorded in the NCMP and, where missing, supplemented with ethnic background as recorded in the child's primary care electronic health record. ⁹ School year of participation in the National Child Measurement Programme (NCMP), Reception participants are aged 4-5 years and Year 6 participants are aged 10-11 years. ¹⁰ Academic year of participation in the National Child Measurement Programme (NCMP). Academic years run from September to July. ¹¹ Local authority of school where child participated in the NCMP. ¹² Whether the youngest and oldest child were of the same or different sex. ¹³ Time difference, calculated in months, between the oldest and youngest child's NCMP measurements. Cells highlighted in bold indicate occasions where the estimates are significantly difference to the reference group in the multivariable models.
