Appendix 2: Supplementary Figures

Supplemental Figure 1. Funnel plot of vaccine effectiveness studies. The funnel plots are centered at 0 (i.e., at the value under the null hypothesis of no effect) and display the studies' results (x-axis) and their precision (y-axis). In the meta-analyses, the result is expressed as log risk ratios (RRs) and the precision is represented by the standard error of the estimates. Each dot represents a single observation. The funnel plot shows an asymmetry indicating potential publication bias.

Supplemental Figure 2. Egger's publication bias plot of vaccine effectiveness studies. The X-axis represents the precision size, while the Y-axis depicts the standardized effect size. Each data point represents an individual study, with its position indicating the observed effect size and standard error. Studies deviating from the regression line suggesting potential publication bias (t value of Egger's test = -2.86, $p=0.01$).

Supplemental Figure 3. Begg's funnel plot of vaccine effectiveness studies. The X-axis is expressed as log risk ratios (RRs) and the Y-axis depicts the standardized effect size. Each data point represents an individual study, with its position indicating the observed effect size and standard error. Smaller studies scattered widely at the bottom, and larger studies clustered closer to the top. Studies deviating from the regression line suggesting potential publication bias (z value of Begg's test =2.09, p=0.04).

Supplemental Figure 4. Filled funnel plot of vaccine effectiveness studies. The filled funnel plot integrates black dots representing included studies and gray circles representing additional studies imputed through trim-and-fill analysis to address potential publication bias. The inclusion of 11 imputed studies in the trim-and-fill analysis suggests no significant publication bias after adjustment (t value of adjustment Egger’s test = -0.38, $p=0.71$).

Supplemental Figure 5. The sensitive analysis of vaccine effectiveness studies. Each line or data point represents a different sensitivity analysis scenario, such as excluding certain studies or using different statistical models. When points cluster closer to the central reference line, it indicates greater robustness and consistency in the results across different scenarios, suggesting higher reliability. The results were robust through removing a single study each time.

Supplemental Figure 6. Forest plot for vaccine effectiveness of different vaccines doses for the BNT162b2 vaccine on preventing Omicron infections. The red square symbolizes the point estimate for each study, with its size proportional to the study's weight relative to the summary estimate. The black diamond symbol represents the overall effect estimate derived from the meta-analysis. A random effects model was employed when I² exceeded 50%.

Supplemental Figure 7. Forest plot for vaccine effectiveness of different vaccines doses for the CoronaVac vaccine on preventing Omicron infections. The red square symbolizes the point estimate for each study, with its size proportional to the study's weight relative to the summary estimate. The black diamond symbol represents the overall effect estimate derived from the meta-analysis. A random effects model was employed when I² exceeded 50%.

Appendix 3: Supplementary Table
Supplemental Table 1. Characteristics of included studies.

Name	Country	Study design	Age	Sample size (cases/total)	Vaccination type	Time	Main outcome
Amir 2022	Israel	Cohort study	5-15 years	Not provided /1158289	2-dose BNT162b2 mRNA vaccine 3-dose BNT162b2 mRNA vaccine	14-35 days 14-60 days	In 5-10 years, the 2-dose decreased confirmed infection rates by 2.3 times (2.0-2.5) lower. In 12-15 years, the 3-dose decreased confirmed infection rates by 3.3 times (2.8-4.0).
