Supplementary Material S2

Global Burden of Disease dataset

The data utilised for this observational analysis of ILD were sourced from the Global Burden of Disease (GBD) database, which aggregates mortality and disability data pertaining to a range of global health issues. This includes information such as deaths, death rates, years of life lost due to premature mortality, prevalence, and incidence rates.

The GBD methodology is clearly explained on the website (<https://www.healthdata.org/data-tools-practices/data-collection>).

In summary, the GBD employs a comprehensive approach that incorporates systematic reviews, survey data, disease registries, hospital administrative records, claims data, as well as inpatient and outpatient records, alongside case notifications to estimate disease incidence (for the GBD methodology regarding ILDs and sarcoidosis data collection is provided on pages 888-892 in the following document: [https://www.thelancet.com/cms/10.1016/S0140-6736\(20\)30925-9/attachment/7709ecbd-5dbc-4da6-93b2-3fd0bedc16cc/mmc1.pdf](https://www.thelancet.com/cms/10.1016/S0140-6736(20)30925-9/attachment/7709ecbd-5dbc-4da6-93b2-3fd0bedc16cc/mmc1.pdf)). Disease classifications within the GBD database adhere to the International Classification of Diseases (ICD) coding system. The collation and dissemination of data are managed by the GBD Collaborators, and the datasets are made publicly accessible for further analysis.

We queried the data on the 1st level cause, selecting the same 24 European Countries, and directly extracted the prevalence rates for each year and for each Country. We used prevalence data for ILDs and sarcoidosis (ICD-10 codes “J84 – *other interstitial lung diseases*” + “D86 – *sarcoidosis*”) as a proxy. We extracted the average annual prevalence rate change for each European Country for the interval 2010-2019, as no more restricted intervals were possible.

Supplementary Material S3

Segmented regression model

The model assesses the overall trends in mortality, initially with no Joinpoints, and tests for significant changes in the model with sequential addition of points where there is significant change in the slope of the line. The model also computes an estimated average annual percent change for each trend by fitting a regression line to the natural logarithm of the rates. The log-linear transformation allows us to approximate normal distributions and, by estimating the annual percentage change, we were able to assess change in mortality trend at a constant percentage per year.

On the Joinpoint software input tabs, we used the following options on the basis of Irimata et al. indications (Irimata KE, Bastian BA, Clarke TC, Curtin SC, Badwe R, Rui P. Guidance for Selecting Model Options in the National Cancer Institute Joinpoint Regression Software. *Vital Health Stat 1*. 2022 Oct;(194):1-22. PMID: 36255743):

- *Heteroscedastic/correlated errors option (Input File tab)* → we used Standard Error (Provided): this option is the loosest as it allows the errors to be both homoscedastic and heteroscedastic, based on the variance structure provided in the data file. Mortality data are suggested to be treated as uncorrelated as no year-on-year correlation is supposed.
- *Log transformation (Input File tab)* → we applied the log transformation option, as it best suited our need to obtain the relative differences and discuss the APCs, rather than looking at absolute rates.
- *Modelling method and constraints (Method and Parameters tab)* → we adopted the Grid model in this case and used the following constraints: minimum number of observations from a joinpoint to either end of the data = 2; minimum number of observations between two joinpoints = 1; number of points to place between adjacent observed values in the grid search = 0.

- Number of joinpoints (minimum and maximum number of joinpoints) (Method and Parameters tab)

→ we used 0 as minimum number of joinpoint and increased to 1 the number of maximum joinpoints (default 0 for less than 7 observation points – years in our case).

- Model selection method (Method and Parameters tab) → as we had less than 10 time points, we applied the Bayesian Information Criterion (BIC) model.

Supplementary Material S5

Direct standardisation method

For direct standardisation we used the STATA command *dstdize* using the following syntax:

`dstdize charvar popvar stratavars, by(groupvars) [dstdize_options]` where *charvar* is the characteristic (i.e., IPF deaths) to be standardised across different subpopulations identified by *groupvars* (i.e., country and year), *popvar* defines the weights used in standardization (i.e., number of residents in each country and in each year), *stratavars* defines the strata across which the weights are to be averaged in *dstdize* (i.e., sex and age groups).

Therefore, with this command, it is possible to perform a direct standardisation adjusted for covariates of interest. We used the following code:

```
dstdize deaths population age sex using ("reference population"), by (country year).
```

Crude mortality rates and rate ratios calculation

We calculated the crude mortality rates dividing the number of J84.1 deaths by the total resident population for each year and for each country.

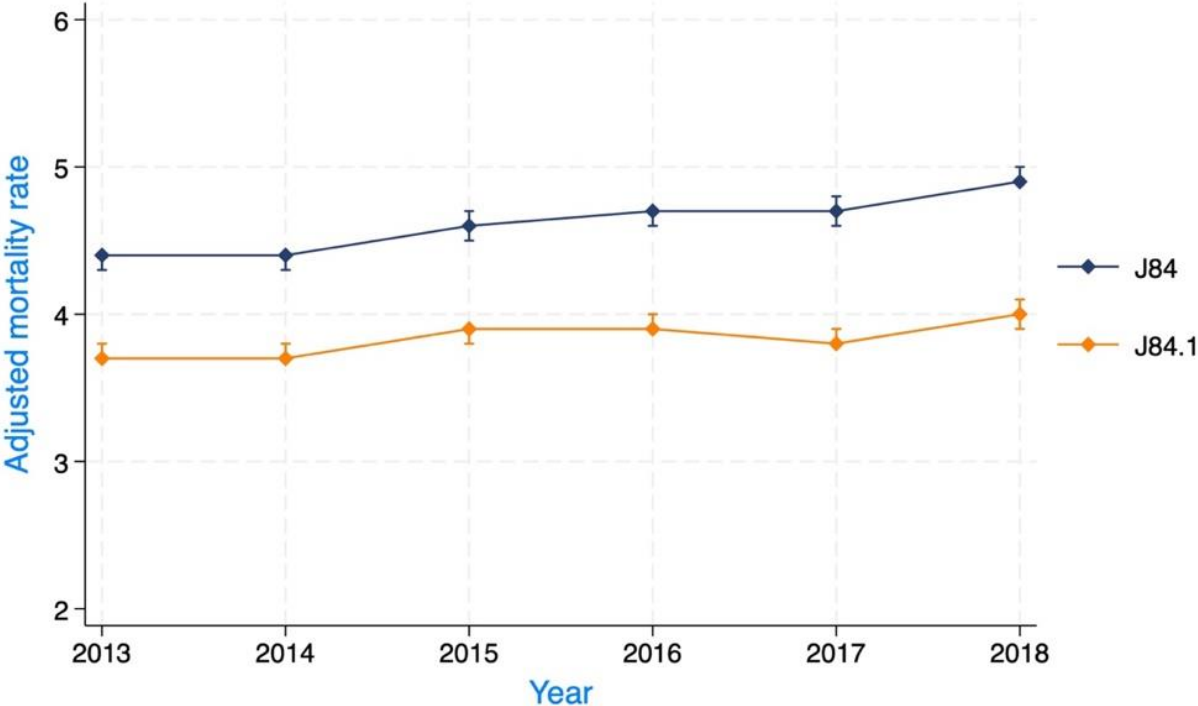

To obtain mortality rate ratios in each country, we compared the adjusted mortality rate of a certain category with the adjusted mortality rate of a selected reference (i.e., male vs female).
