ABSTRACT

Objectives: Hepatitis C virus (HCV) infection poses a global health challenge. By the end of 2021, the World Health Organization estimated that less than a quarter of global HCV infections had been diagnosed. There is a need for a public health tool that can facilitate the identification of infected individuals and link them to testing and treatment, and that can be customized for each country.

Methods: We derived and validated a risk score to identify infected individuals in Egypt and demonstrated its utility. Utilizing data from the 2008 and 2014 Egypt Demographic and Health Surveys, two risk scores were constructed through multivariable logistic regression analysis. A range of diagnostic metrics was then calculated to evaluate the performance of these scores.

Results: The 2008 and 2014 risk scores exhibited similar dependencies on sex, age, and type of place of residence. Both risk scores demonstrated high and similar areas under the curve of 0.77 (95% CI: 0.76-0.78) and 0.78 (95% CI: 0.77-0.80), respectively. For the 2008 Risk Score, sensitivity was 73.7% (95% CI: 71.5-75.9%), specificity was 68.5% (95% CI: 67.5-69.4%), positive predictive value (PPV) was 27.8% (95% CI: 26.4-29.2%), and negative predictive value (NPV) was 94.1% (95% CI: 93.5-94.6%). For the 2014 Risk Score, sensitivity was 64.0% (95% CI: 61.5-66.6%), specificity was 78.2% (95% CI: 77.5-78.9%), PPV was 22.2% (95% CI: 20.9-23.5%), and NPV was 95.7% (95% CI: 95.4-96.1%). Each score was validated by applying it to a different survey database than the one used to derive it.

Conclusions: Implementation of HCV risk scores is an effective strategy to identify carriers of HCV infection and to link them to testing and treatment at low cost to national programs.

Keywords: Hepatitis C virus, viral hepatitis, risk score, Egypt, Demographic Health Survey.

What is already known on this topic

The World Health Organization has set a global target to eliminate HCV infection as a public health problem by 2030. The Middle East and North Africa (MENA) region is the most affected by HCV infection. While mass testing and treatment programs may be relevant in countries with high prevalence, other countries exhibit relatively low HCV prevalence, rendering such programs less cost-effective. There is a need for a public health tool that can aid in identifying potentially infected individuals to link them to testing and treatment.

What this study adds

This study demonstrated the effectiveness of a risk score as a non-invasive public health tool comprising a few simple questions to identify carriers of HCV infection and link them to testing and treatment. Specifically demonstrated in Egypt, the tool exhibited good diagnostic accuracy, as indicated by various diagnostic performance metrics.

How this study might affect research, practice or policy

A single national survey for HCV infection can be sufficient to develop an effective risk score for HCV infection, which can become an integral component of the national strategy to eliminate this infection in a given country.

INTRODUCTION

Hepatitis C virus (HCV) infection is a global public health challenge[1, 2] and a major cause of morbidity and mortality, resulting in liver cancer, fibrosis, and cirrhosis[3]. By end of 2021, the World Health Organization (WHO) estimated that 58 million people were infected with HCV, but only 15 million of them were diagnosed and only 9 million received treatment[4]. Direct-acting antivirals (DAA) offer highly effective treatment to cure this infection and to prevent progression toward severe forms of liver disease[5], as well as an opportunity to reduce HCV transmission through treatment as prevention[6, 7]. Accordingly, the WHO has set a global target to eliminate HCV infection as a public health problem by 2030[2, 8].

While DAAs are becoming accessible globally, it has been challenging to identify carriers of this infection so as to treat them, especially in the Middle East and North Africa (MENA), the region most affected by HCV infection and where most infected persons remain undiagnosed[9, 10].

Limited resources have made it challenging for viral hepatitis programs to find low-cost and cost-effective approaches to identify infected persons. While mass testing and treatment programs may be relevant in high prevalence countries, other countries have relatively low HCV prevalence making such programs less cost-effective[10-16]. While low-cost point-of-care tests (POCs) have been beneficial in some countries, such as Egypt[17], they remain relatively expensive for countries like Pakistan, which bear a substantial share of the global burden[18-20]. There is a need for a public health tool that can assist in identifying potentially infected persons so as to link them to testing and treatment.

One such tool is the use of risk scores to identify potentially infected individuals. A risk score comprises a small set of simple questions that can be used to assess the likelihood that an individual has a specific health condition[21-24], in this case, HCV infection. Such risk scores

1
2
3 have proven influential as public health tools for a range of health conditions, such as
4
5 diabetes[21-24].
6
7

8 In this study, we demonstrate the application of this public health tool for HCV infection in
9
10 Egypt, aiming to illustrate the public health value and practical utility of developing HCV risk
11
12 scores in various countries. The risk score derived here is not intended for universal application
13
14 across diverse settings; it is specifically designed for Egypt. However, the concept and analytical
15
16 approach can be adapted to other countries by considering the local HCV epidemiology to
17
18 determine the relevant factors and their respective weights for inclusion in a score tailored to
19
20 each specific context.

22
23

24 **METHODS**

25 *Egypt Demographic and Health Surveys*

26
27
28 The Egypt Demographic and Health Survey (EDHS) is a national survey that collected data
29
30 pertaining to the health and demographics of a nationally representative sample of the resident
31
32 population of Egypt, including HCV infection[25, 26]. The EDHS that included HCV
33
34 biomarkers was conducted in 2008 and 2014 and used rigorous sampling methods[27]. Details
35
36 on study design, data collection, and laboratory methods can be found in El-Zanaty et al.[25, 26].
37
38 HCV antibody testing was done using a third generation enzyme-linked immunosorbent assay
39
40 (ELISA), the Enzyme Immunoassay Adlatis EIAgen HCV Ab test (Adaltis Inc., Montreal,
41
42 Canada)[25, 26]. All samples that were positive in the ELISA assay and 5% of the negative
43
44 samples were then retested using a more specific assay, the chemiluminescent microplate
45
46 immunoassay (CMIA ARCHITECT plus i1000SR, Abbott Diagnostic, USA)[25, 26]. If a
47
48 sample was positive in both the ELISA and the CMIA testing, it was also tested for current
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 active infection, using real-time, reverse-transcription polymerase chain reaction (RT-qPCR)
4 testing to detect HCV ribonucleic acid (RNA)[25, 26]. Samples were further retested for internal
5 and external quality assurance[25, 26]. Here we restrict our analyses to the HCV antibody
6 results.
7
8
9
10

11
12 Data from the EDHS 2008 and EDHS 2014 were downloaded with permission from Measure
13 DHS[28]. The data can be accessed through application to the DHS Program at
14 <https://dhsprogram.com>. For purposes of this study, the EDHS individual database was merged
15 with the HCV biomarker database, based on established guidelines for managing DHS data[27].
16 All individuals with results for HCV antibody testing were included in the analysis.

24

25 ***Risk score derivation***

26
27 Associations of HCV antibody positivity (seropositivity) with a priori variables that are easy to
28 evaluate in a primary healthcare setting, and that can be included in a risk score, were
29 investigated. These variables included sex (male versus female), age (5-year age strata), and type
30 of place of residence (urban versus rural). Frequency distributions were generated to describe
31 demographic and clinical profiles of tested individuals.
32
33
34
35
36
37
38
39

40 Chi-square tests and univariable logistic regression were implemented to investigate
41 associations. Participants younger than 15 years of age were excluded as this age group was not
42 included in the EDHS 2008 and has low HCV prevalence (Table S1)[6, 29-31]. Odds ratios
43 (ORs), 95% confidence intervals (CIs), and p-values were reported. Covariates with p-values
44 ≤ 0.1 in univariable regression analysis were considered possibly associated with HCV
45 seropositivity. These were included in the multivariable analysis for estimation of adjusted ORs
46 (AORs) and associated 95% CIs and p-values. No other forward or backward elimination for
47 variable selection was used. Covariates with p-values ≤ 0.05 in the multivariable model were
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 considered predictors of HCV seropositivity. Univariable and multivariable analyses were
4
5 adjusted for sampling weights.
6
7

8 A risk score was constructed based on the β -coefficients obtained from the multivariable
9
10 regression model. β -coefficients were multiplied by a factor of 10 and then rounded to the
11
12 nearest integer. The total risk score was calculated by adding the individual scores. To keep the
13
14 score simple enough for use in primary healthcare and other general population settings, we did
15
16 not consider any interaction terms.
17
18

19 20 ***Performance and validation of the risk score*** 21

22
23 A receiver operating characteristics (ROC) curve was plotted to investigate the performance of
24
25 the risk score in predicting HCV seropositivity at different score cut-offs. A larger area under the
26
27 curve (AUC), also called the c-index, indicates better performance of the risk score. The cut-off
28
29 for the score was determined by maximizing the sum of the sensitivity and specificity.
30
31

32 Sensitivity is the probability that the risk score will yield a positive diagnosis in a subject who is
33
34 truly HCV antibody-positive. Specificity is the probability that the risk score will yield a
35
36 negative diagnosis in a subject who is truly HCV antibody-negative.
37
38

39 Performance of the risk score was also investigated by estimating the positive predictive value
40
41 (PPV) and the negative predictive value (NPV) of the risk score. PPV is the probability that a
42
43 subject with a positive diagnosis per the risk score is truly HCV antibody-positive. NPV is the
44
45 probability that a subject with a negative diagnosis per the risk score is truly HCV antibody-
46
47 negative. The proportion of subjects who have scores greater than or equal to the cut-off of the
48
49 risk score was estimated to determine the proportion of individuals that need to be biochemically
50
51 tested for HCV antibodies.
52
53
54
55
56
57
58
59
60

1
2
3 To validate the performance of the EDHS 2008 risk score, it was applied to the EDHS 2014 data,
4 providing an independent validation with a dataset different from the one used for its derivation.
5
6 Performance diagnostics were subsequently assessed. Given the pronounced cohort effect in the
7
8 epidemiology of HCV infection in Egypt[6, 29-31], the age variable was adjusted to reflect the
9
10 6-year interval between the surveys. For example, individuals who were 11 years old in 2008
11
12 would have been 17 years old at the time of the second survey in 2014. The same approach was
13
14 also used to validate the EDHS 2014 risk score—it was applied to the EDHS 2008 database and
15
16 performance diagnostics were assessed.
17
18
19
20
21

22 While the cut-off for the score was determined by maximizing the sum of sensitivity and
23
24 specificity, this cut-off can be adjusted as needed from a programmatic standpoint to optimize a
25
26 specific diagnostic metric, such as sensitivity instead of specificity. To illustrate this flexibility,
27
28 an additional analysis was incorporated featuring a variety of score cut-offs, resulting in diverse
29
30 values of sensitivity, specificity, PPV, and NPV. Such additional analysis enables program
31
32 managers and readers to discern the trade-offs among these diagnostic metrics and observe the
33
34 implications of selecting an alternative programmatic approach, such as prioritizing the
35
36 optimization of sensitivity over specificity.
37
38
39
40

41 Analyses were conducted in Stata version 16.1 (Stata Corporation, College Station, TX, USA).
42
43 The study was reported following the Strengthening the Reporting of Observational Studies in
44
45 Epidemiology (STROBE) guidelines (Table S2).
46
47

48 **RESULTS**

49
50
51 In the 2008 EDHS, 11,126 individuals 15-59 years of age were tested, of whom 1,571 were
52
53 antibody-positive[25]. The 2014 EDHS included children 1-14 years of age in addition to adults
54
55 15-59 years of age[26]. In this latter survey, 26,047 individuals were tested of whom 1,456 were
56
57
58
59
60

antibody-positive[26].

Characteristics of individuals who were tested for HCV antibodies and the proportion of each population stratum that was HCV antibody-positive are shown in Table S1 for both of the EDHS surveys. Results of both surveys were consistent, taking into account the age shift in the national cohort with the passage of 6 years between the EDHS 2008 and EDHS 2014.

HCV seropositivity was strongly associated with sex, age, and place of residence in both national surveys (Table 1 and Table S3). Male sex and rural residence were associated with higher seropositivity. Seropositivity increased rapidly with age.

The 2008 and 2014 Egypt Hepatitis C Risk Scores derived using the EDHS 2008 and EDHS 2014 data, respectively, are shown in Figure 1. The 2008 Risk Score had a range of 0-41. The 2014 Risk Score had a range of 0-53. Both showed similar dependence on sex, age, and type of place of residence. Both demonstrated high and similar AUCs (Figure 2). The AUC was 0.77 (95% CI: 0.76-0.78) for the 2008 Risk Score and 0.78 (95% CI: 0.77-0.80) for the 2014 Risk Score. The highest sum of sensitivity and specificity was obtained at a score cut-off value of 22 for the 2008 Risk Score and at a cut-off of 34.5 for the 2014 Risk Score.

For the 2008 Risk Score, sensitivity was 73.7% (95% CI: 71.5-75.9%), specificity was 68.5% (95% CI: 67.5-69.4%), PPV was 27.8% (95% CI: 26.4-29.2%), and NPV was 94.1% (95% CI: 93.5-94.6%) (Table 2). For the 2014 Risk Score, sensitivity was 64.0% (95% CI: 61.5-66.6%), specificity was 78.2% (95% CI: 77.5-78.9%), PPV was 22.2% (95% CI: 20.9-23.5%), and NPV was 95.7% (95% CI: 95.4-96.1%). The proportion of the population 15-59 years of age that needed to be biochemically tested for HCV antibodies was 37.2% (95% CI: 36.3-38.1%) using the 2008 Risk Score and 25.5% (95% CI: 24.9-26.2%) using the 2014 Risk Score. Of all HCV-infected persons in the EDHS samples, application of this score would have diagnosed (that is

1
2
3 identified; sensitivity) 73.7% (95% CI: 71.5-75.9%) and 64.0% (95% CI: 61.5-66.6%) of all
4
5 HCV antibody-positive persons in samples of the EDHS 2008 and 2014, respectively.
6
7

8 When the 2008 Risk Score was applied to the EDHS 2014 data, the AUC was 0.75 (95% CI:
9
10 0.74-0.77), the sensitivity was 66.1% (95% CI: 63.5-68.6%), and the specificity was 72.3% (95%
11
12 CI: 71.5-73.1%) (Table 2). These performance indicators were similar to the original
13
14 performance indicators generated using the EDHS 2008 data, as well as to the performance
15
16 indicators of the 2014 Risk Score on the EDHS 2014 data. Therefore, this application validates
17
18 this risk score. A similar outcome was found when the 2014 Risk Score was applied to the EDHS
19
20 2008 data, also providing a validation of the 2014 risk score.
21
22
23
24

25 Figure 3 displays the proportion of HCV infections in the population that are diagnosed as a
26
27 function of the proportion of the population that needs to be tested to identify these infections,
28
29 using each of EDHS 2008 and EDHS 2014 data. The figure shows the effect of prioritization of
30
31 testing for those with higher to lower risk score. This provides a demonstration of the utility of
32
33 using the risk score: a large proportion of HCV infections can be diagnosed by testing only a
34
35 small proportion of the population. It is most efficient programmatically to start testing
36
37 individuals with the highest risk score and progressively moving on to those with lower and
38
39 lower risk scores. As testing is expanded to those with low risk scores, the yield in identifying
40
41 more HCV infections is very limited.
42
43
44
45

46 Table 3 illustrates the implications of selecting various score cut-offs, providing insight into the
47
48 trade-offs among different diagnostic metrics, as well as the proportion of the population
49
50 requiring biochemical testing and the proportion of all HCV-infected individuals identified
51
52 through the application of this score. For instance, by enhancing the specificity of the risk score,
53
54 the PPV increases, and the proportion of the population necessitating testing decreases. This
55
56
57
58
59
60

1
2
3 reduction in testing requirements helps alleviate costs and streamline the logistics of the test-and-
4
5 treat program. However, this enhanced program efficiency comes at the expense of lower NPV
6
7 and sensitivity, implying a smaller proportion of HCV-infected individuals in the population
8
9 being identified through the risk score.
10
11

12 13 **DISCUSSION**

14
15 We demonstrated that a risk score that consists of few simple questions that are easy to evaluate
16
17 in a primary healthcare setting or implemented through a website or an app that helps persons
18
19 identify their risk of being HCV infected, provides an effective and non-invasive public health
20
21 tool to identify carriers of HCV infection and to link them to testing and treatment. Biochemical
22
23 testing methods to identify HCV infected persons are invasive and time-consuming and require
24
25 human and financial resources, as well as complex logistics, making them less scalable,
26
27 particularly in resource-limited settings. In contrast, initial screening using a risk score can be
28
29 easily administered or self-administered, is non-invasive, and requires minimal resources and
30
31 logistics. Therefore, HCV risk scores can be an indispensable strategy for the global response to
32
33 attain the target of HCV elimination as a public health problem by 2030.
34
35
36
37
38

39 While the concept of a risk score shares similarities with risk-based testing, which has been
40
41 implemented in some countries, predominantly in higher-income nations[32-34], the risk score
42
43 approach transcends mere risk-based testing. It enables a broader application across various
44
45 settings and situations and can significantly contribute to raising awareness of the infection
46
47 among the general population. The risk score approach represents a tool that addresses several
48
49 public health needs simultaneously, extending the application of risk-based testing beyond
50
51 conventional healthcare settings. Moreover, it entails minimal costs and logistics, making it
52
53 feasible even in resource-limited settings.
54
55
56
57
58
59
60

1
2
3 Remarkably, the risk score, comprising three simple questions, demonstrated considerable
4 diagnostic accuracy, as evidenced by the values of various diagnostic metrics, including AUC,
5 sensitivity, specificity, PPV, and NPV. Of particular note is the high NPV, ensuring that a
6 negative result is highly unlikely to be a false negative, thereby obviating the need for
7 individuals with a negative outcome using the score to undergo testing for HCV antibodies. The
8 score also identified 73.7% and 64.0% of all HCV infections in the EDHS 2008 and EDHS 2014
9 samples, respectively. Thus, the score fulfills its objective of facilitating the efficient
10 identification of individuals with HCV infection while minimizing the necessity for conducting
11 biochemical testing. This underscores the value of this approach in identifying as many HCV-
12 infected persons as early as possible and initiating treatment before progression to serious
13 clinical disease.

14
15 This approach was demonstrated for Egypt, considering the availability of two EDHS surveys to
16 derive and validate the score. The two scores exhibited comparable structures and diagnostic
17 performances, with minor differences attributed to sampling variation of the same population
18 across two distinct rounds of the EDHS surveys. Each score was validated by applying it to a
19 database other than the one used to derive it. The latter application yielded a diagnostic
20 performance that was comparable to the original diagnostic performance against the database
21 used to originate it. This highlights how a single national survey for HCV infection may be
22 sufficient to develop an effective risk score for this infection, and that can become an integral
23 component of the national response to eliminate HCV infection.

24
25 The approach demonstrated in this study can be applied in other countries, including those in the
26 MENA region. In countries where nationally representative population-based surveys have been
27 conducted, these surveys can serve as the basis for deriving the risk score, as was done in this

1
2
3 study. However, only three MENA countries—Egypt, Libya, and Pakistan—have conducted
4 such surveys[25, 26, 35, 36]. For countries where such surveys are not available[10-16], the risk
5 score can still be derived using data from available regional surveys. Alternatively, if regional
6 surveys are not available, the effects of risk factors for infection can be pooled, either in terms of
7 odds ratios or relative risks, using data from analytical studies[37]. These effects can also be
8 derived from meta-regression analyses applied to all available HCV prevalence studies for each
9 country[38-45].

10
11 While this study focused on demonstrating the utility of this concept as a public health tool,
12 actual application of this approach to different countries can be enhanced for even higher
13 diagnostic accuracy. One extension could be adding more variables to the score in a manner
14 tailored to the local epidemiology of each country. For instance, province or city of birth and/or
15 current residence, prior exposure to an HCV mode of transmission[37], or history of HCV
16 infection in the family, could be added, among others. Given that the risk of exposure to HCV
17 infection varies immensely by at-risk population type and shows a distinctive hierarchy[46], an
18 additional component to the score could be to integrate the at-risk population type as a
19 variable[41, 46], thereby further enhancing the diagnostic accuracy of the score. Testing
20 strategies, therefore, could be highly efficient in identifying HCV infected persons at a modest
21 cost.

22
23 However, caution must be exercised to prevent the creation of stigma associated with HCV
24 infection or the use of an HCV risk score. For instance, it may not be feasible to include
25 questions about stigmatized behaviors in the MENA context, such as injecting drug use or
26 specific sexual practices, when the score is applied in general population settings like primary
27 healthcare. However, such questions may be appropriate in other settings, such as voluntary
28

1
2
3 counseling and testing (VCT) centers or outreach efforts by community organizations working
4 with the most at-risk populations[47]. It is important also for the risk score to factor community
5 acceptance in its design and implementation, ensuring it addresses the specific needs of certain
6 groups, such as women of childbearing age in contexts where the risk of HCV vertical
7 transmission is not negligible[48-50].
8
9

10
11
12 The application of HCV risk scores can be influenced by programmatic considerations and
13 variations in context. This may necessitate prioritizing specific diagnostic metrics, such as
14 sensitivity over specificity. The approach presented here demonstrates an inherent flexibility of
15 the score, allowing adjustments to address specific programmatic needs, as illustrated by the
16 analysis using different cut-off points (Table 3). However, it is critical to acknowledge the
17 inherent trade-offs between diagnostic metrics. Optimizing one metric, such as sensitivity, will
18 inevitably impact others, like specificity. Therefore, careful consideration is essential to align the
19 score's cut-off with the specific programmatic context and its corresponding needs.

34 This study has limitations. For ease of use in primary healthcare and more broadly by the public,
35 a risk score has to be simple. Accordingly, it cannot fully represent the complex epidemiology of
36 HCV infection, such as interactions among risk factors. This risk score was derived for Egypt,
37 which may not benefit from this risk score, given that this country has opted for mass testing of
38 its entire population[17]. Derivation of a risk score typically requires at least one round of a
39 population-based survey, ideally at the national level, but many countries may not have such
40 survey data to be able to easily derive a risk score. The risk score was derived for a high-burden
41 country, and utility of this approach still needs to be demonstrated for countries with low HCV
42 prevalence. Nonetheless, this approach may prove to have higher utility in countries with low
43 HCV prevalence than in countries with high HCV prevalence, as HCV epidemiology shows a

7

8 **Conclusions**

9

10
11 An HCV risk score can be derived using only one round of a population-based survey and offers
12
13 an effective, simple, non-invasive strategy to identify carriers of HCV infection and to link them
14
15 to testing and treatment, at low cost. This public health tool can be implemented and used for
16
17 prioritizing populations for interventions with minimal logistical complexity and cost, especially
18
19 in resource-limited countries.

Abbreviations: aOR, Adjusted odds ratio; CI, Confidence interval; EDHS, Egypt Demographic and Health Survey; HCV, Hepatitis C virus; Ref, Reference category.

*The analysis applied the EDHS sampling weights.

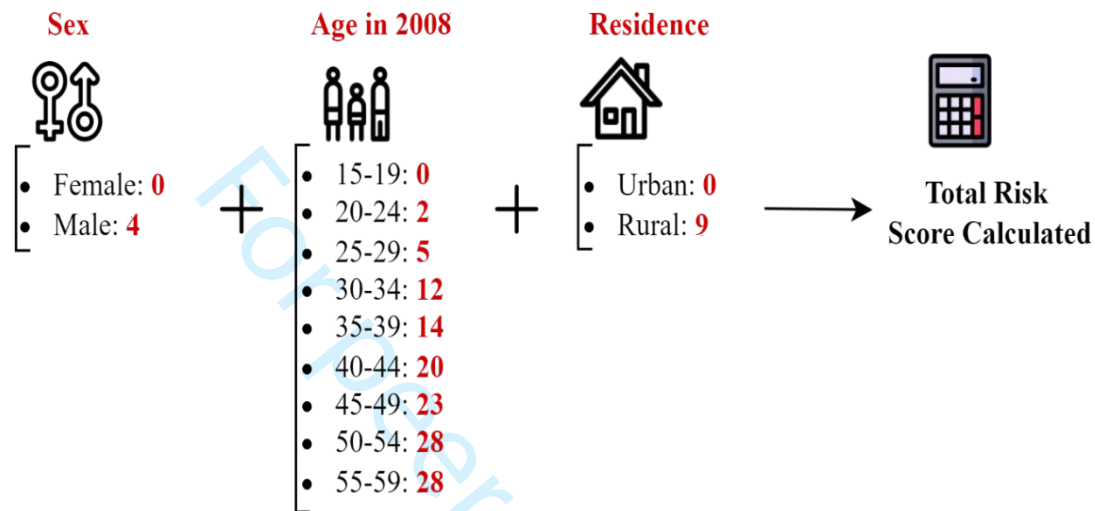

†The odds ratio was adjusted for sex, age, and type of place of residence.

‡ β -coefficients were based on the multivariable regression analysis.

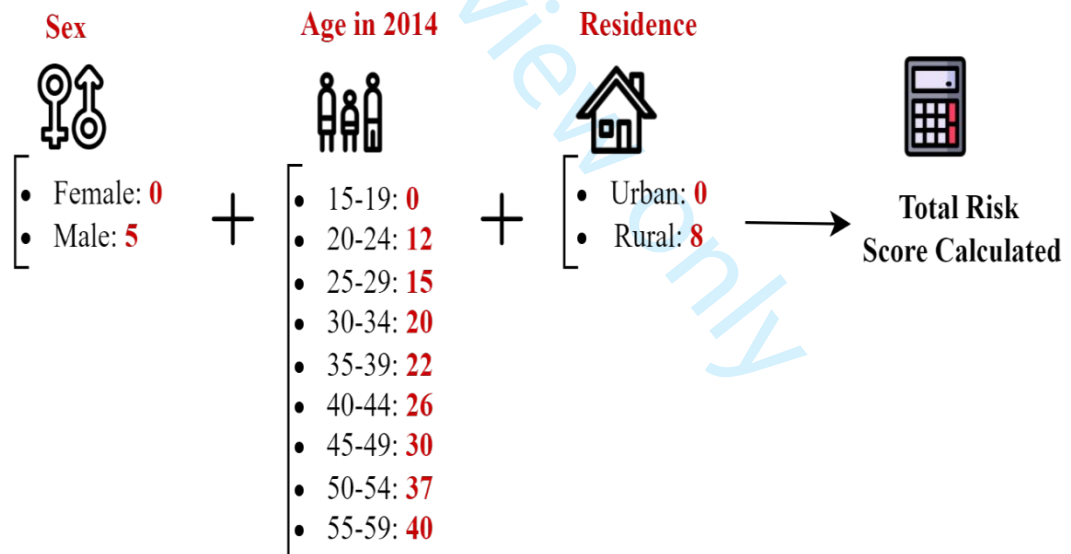

§The risk score was calculated by multiplying the β coefficient by 10 and then rounding the result to the nearest integer.

Figure 1. Mathematical formula of the derived Egypt Hepatitis C Risk Score. A) Egypt Hepatitis C Risk Score using the EDHS 2008. B) Egypt Hepatitis C Risk Score using the EDHS 2014.

A.

B.

Abbreviations: EDHS, Egypt Demographic and Health Survey; ROC, receiver operating characteristics.

The two scores exhibited comparable structures and diagnostic performances, with minor differences attributed to sampling variation of the same population across two distinct rounds of the EDHS surveys. Details on the derivation of these scores are provided in the Methods and Results sections.

Figure 2. Diagnostic performance of the Egypt Hepatitis C Risk Score using the area under the (ROC) curve. A) Using the EDHS 2008 data. B) Using the EDHS 2014 data.

A.

B.

Abbreviations: EDHS, Egypt Demographic and Health Survey; ROC, receiver operating characteristics.

Table 2 Performance of the Egypt Hepatitis C Risk Score

	AUC (95% CI)	Risk score cut-off*	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Proportion needing testing (95% CI)
Derived risk scores							
Risk score derived using the EDHS 2008	0.77 (0.76-0.78)	22.0	73.7 (71.5-75.9)	68.5 (67.5-69.4)	27.8 (26.4-29.2)	94.1 (93.5-94.6)	37.2 (36.3-38.1)
Risk score derived using the EDHS 2014	0.78 (0.77- 0.80)	34.5	64.0 (61.5-66.6)	78.2 (77.5-78.9)	22.2 (20.9-23.5)	95.7 (95.4-96.1)	25.5 (24.9-26.2)
Validation of risk scores							
2008 risk score applied to the EDHS data 2014†	0.75 (0.74-0.77)	22.0	66.1 (63.5-68.6)	72.3 (71.5-73.1)	21.9 (20.6-23.2)	94.8 (94.3-95.2)	31.7 (30.9-32.5)
2014 risk score applied to the EDHS data 2008‡	0.76 (0.74-0.77)	33.5	70.0 (67.5-72.6)	70.0 (69.0-70.9)	24.7 (23.3-26.1)	94.3 (93.7-94.9)	34.6 (33.7-35.5)

Abbreviations: AUC, Area under the curve; EDHS, Egypt Demographic and Health Survey; HCV, Hepatitis C virus; NPV, Negative predictive value; PPV, Positive predictive value.

*The optimal cut-off for the score was determined by maximizing the sum of the sensitivity and specificity.

†The risk score assumes the age of the individuals in 2008 in order to account for the age shift.

‡The risk score assumes the age of the individuals in 2014 in order to account for the age shift.

Figure 3. Proportion of HCV infections in the population that are diagnosed as a function of the proportion of the population that needs to be tested to identify these infections. The figure shows the effect of prioritization of testing for those with higher to lower risk score. A) Using the EDHS 2008 data. B) Using the EDHS 2014 data.

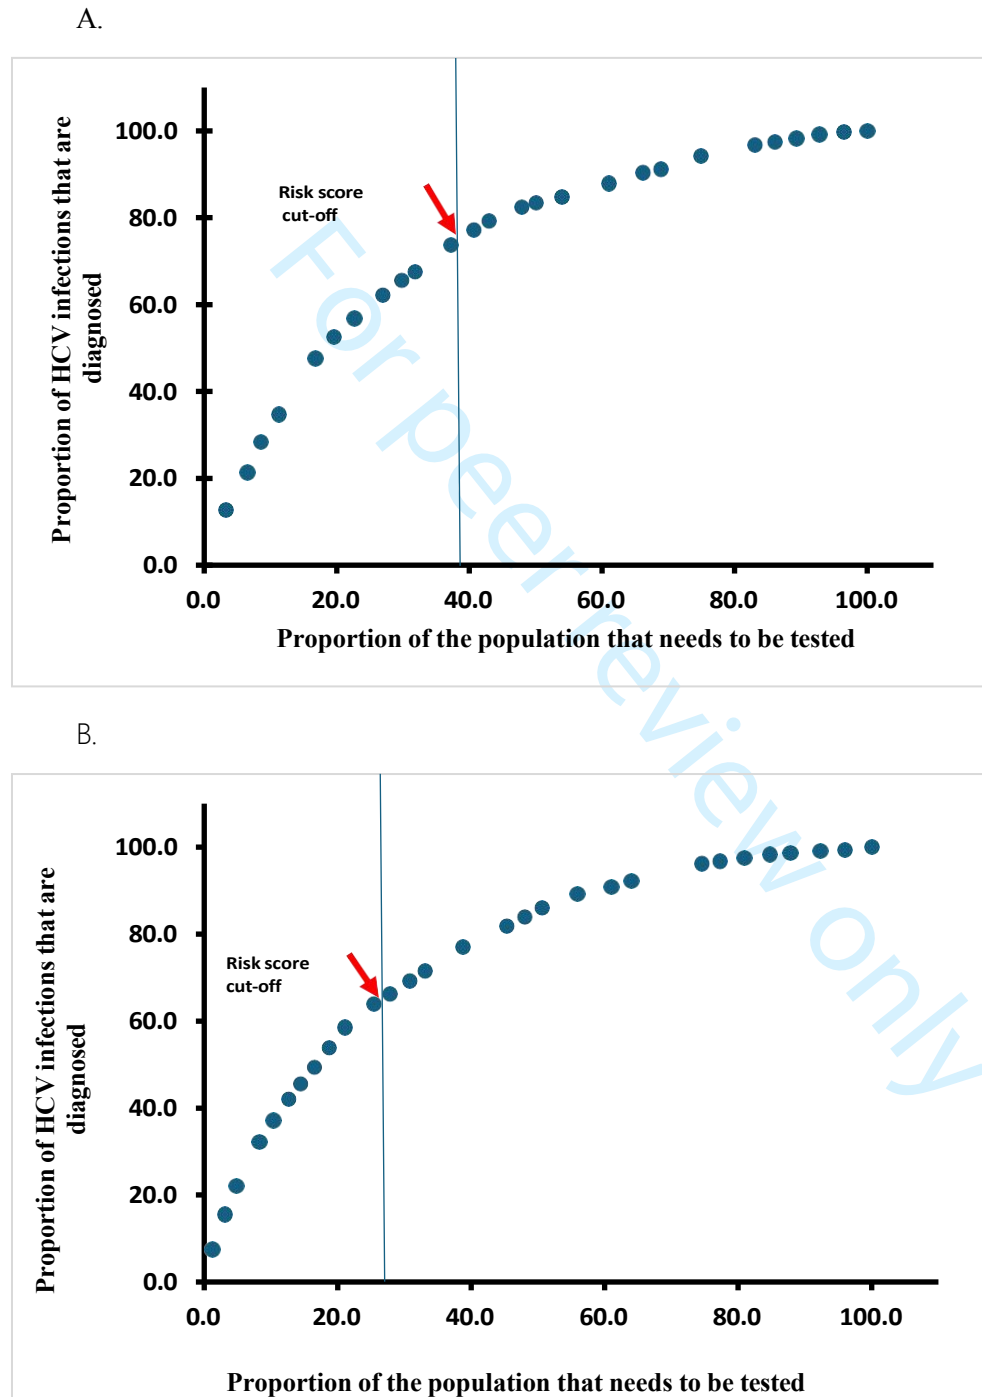

Table 3 Implications of selecting various score cutoffs on the different diagnostic metrics.

Risk score cut-off	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Proportion needing testing (95% CI)	Proportion that are diagnosed (95% CI)

Rural	6,678 (60.0)	1,129 (16.9)		14,092 (54.1)	910 (6.5)	

Abbreviations: EDHS, Egypt Demographic and Health Survey; HCV, Hepatitis C virus

Table S2 STROBE checklist for cross-sectional studies

	Item No	Recommendation	Main Text Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	Abstract
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	Abstract
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	Introduction
Objectives	3	State specific objectives, including any prespecified hypotheses	Introduction
Methods			
Study design	4	Present key elements of study design early in the paper	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score')
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	Methods ('Egypt Demographic and Health Surveys')
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	Methods ('Egypt Demographic and Health Surveys')
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score') & Table S1
Data sources/measurement	8	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score') & Table 1 & Table 3 & Tables S2-S3 & Figures 1-2 & Figure S2
Bias	9	Describe any efforts to address potential sources of bias	Methods ('Risk score derivation' & 'Performance and validation of the risk score') & Table 2 & Figures 1-2
Study size	10	Explain how the study size was arrived at	Not applicable, see Methods ('Egypt Demographic and Health Surveys')
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score') & Tables 1-3 & Table S3
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	Methods ('Risk score derivation' & 'Performance and validation of the risk score')
		(b) Describe any methods used to examine subgroups and interactions	Not applicable, see Methods ('Risk score derivation' & 'Performance and validation of the risk score')
		(c) Explain how missing data were addressed	Not applicable, see Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation')
		(d) If applicable, describe analytical methods taking account of sampling strategy	Not applicable
		(e) Describe any sensitivity analyses	Not applicable
Results			
Participants	13	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed (b) Give reasons for non-participation at each stage (c) Consider use of a flow diagram	Table 1 & Tables S1 & Table S3
Descriptive data	14	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Table 1 & Table S1 & Table S3 & Figure S1
		(b) Indicate number of participants with missing data for each variable of interest	Not applicable, see Methods ('Egypt Demographic and Health Surveys')
Outcome data	15	Report numbers of outcome events or summary measures	Results, Figures 1-2, Figure S1, Tables 1-3 & Table S1
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Table 1 & Table S3

		(b) Report category boundaries when continuous variables were categorized	Tables 1-3 & Table S1 & Table S3
		© If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	Tables 2-3 & Table S3 & Figure S1
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	Results & Table 2 & Figure 2
Discussion			
Key results	18	Summarise key results with reference to study objectives	Discussion, paragraphs 1-3
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	Discussion, paragraph 9
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	Discussion, paragraphs 4-6
Generalisability	21	Discuss the generalisability (external validity) of the study results	Discussion, paragraphs 7-8
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	Acknowledgements

ABSTRACT

Objectives: Hepatitis C virus (HCV) infection poses a global health challenge. By the end of 2021, the World Health Organization estimated that less than a quarter of global HCV infections had been diagnosed. There is a need for a public health tool that can facilitate the identification of people with HCV infection and link them to testing and treatment, and that can be customized for each country.

Methods: We derived and validated a risk score to identify people with HCV in Egypt and demonstrated its utility. Utilizing data from the 2008 and 2014 Egypt Demographic and Health Surveys, two risk scores were constructed through multivariable logistic regression analysis. A range of diagnostic metrics was then calculated to evaluate the performance of these scores.

Results: The 2008 and 2014 risk scores exhibited similar dependencies on sex, age, and type of place of residence. Both risk scores demonstrated high and similar areas under the curve of 0.77 (95% CI: 0.76-0.78) and 0.78 (95% CI: 0.77-0.80), respectively. For the 2008 Risk Score, sensitivity was 73.7% (95% CI: 71.5-75.9%), specificity was 68.5% (95% CI: 67.5-69.4%), positive predictive value (PPV) was 27.8% (95% CI: 26.4-29.2%), and negative predictive value (NPV) was 94.1% (95% CI: 93.5-94.6%). For the 2014 Risk Score, sensitivity was 64.0% (95% CI: 61.5-66.6%), specificity was 78.2% (95% CI: 77.5-78.9%), PPV was 22.2% (95% CI: 20.9-23.5%), and NPV was 95.7% (95% CI: 95.4-96.1%). Each score was validated by applying it to a different survey database than the one used to derive it.

Conclusions: Implementation of HCV risk scores is an effective strategy to identify carriers of HCV infection and to link them to testing and treatment at low cost to national programs.

Keywords: Hepatitis C virus, viral hepatitis, risk score, Egypt, Demographic Health Survey.

Strengths and limitations of this study:

- This study derived a risk score that provides a non-invasive and easily administered method to identify hepatitis C virus carriers and link them to treatment and care.
- The risk score was based on and validated using two rounds of population-based, high-quality national surveys in Egypt.
- The derivation of the risk score used only a few variables and thus may not adequately capture the complex epidemiology of hepatitis C virus infection.
- The derived risk score is specific to Egypt and may not be applicable to populations in other countries.

INTRODUCTION

Hepatitis C virus (HCV) infection is a global public health challenge[1, 2] and a major cause of morbidity and mortality, resulting in liver cancer, fibrosis, and cirrhosis[3]. By end of 2021, the World Health Organization (WHO) estimated that 58 million people were infected with HCV, but only 15 million of them were diagnosed and only 9 million received treatment[4]. Direct-acting antivirals (DAA) offer highly effective treatment to cure this infection and to prevent progression toward severe forms of liver disease[5], as well as an opportunity to reduce HCV transmission through treatment as prevention[6, 7]. Accordingly, the WHO has set a global target to eliminate HCV infection as a public health problem by 2030[2, 8].

While DAAs are becoming accessible globally, it has been challenging to identify carriers of this infection so as to treat them, especially in the Middle East and North Africa (MENA), the region most affected by HCV infection and where most people with HCV infection remain undiagnosed[9, 10]. Limited resources have made it challenging for viral hepatitis programs to find low-cost and cost-effective approaches to identify people with HCV. While mass testing and treatment programs may be relevant in high prevalence countries, other countries have relatively low HCV prevalence making such programs less cost-effective[10-16]. While low-cost point-of-care tests (POCs) have been beneficial in some countries, such as Egypt[17], they remain relatively expensive for countries like Pakistan, which bear a substantial share of the global burden[18-20]. There is a need for a public health tool that can assist in identifying persons potentially living with HCV, to link them to testing and treatment.

One such tool is the use of risk scores to identify individuals potentially living with HCV. A risk score comprises a small set of simple questions that can be used to assess the likelihood that an individual has a specific health condition[21-24], in this case, HCV infection. Such risk scores

1
2
3 have proven influential as public health tools for a range of health conditions, such as
4
5 diabetes[21-24].
6
7

8 In this study, we demonstrate the application of this public health tool for HCV infection in
9
10 Egypt, aiming to illustrate the public health value and practical utility of developing HCV risk
11
12 scores in various countries. The risk score derived here is not intended for universal application
13
14 across diverse settings; it is specifically designed for Egypt. However, the concept and analytical
15
16 approach can be adapted to other countries by considering the local HCV epidemiology to
17
18 determine the relevant factors and their respective weights for inclusion in a score tailored to
19
20 each specific context.
21
22
23

24 **METHODS**

25 *Egypt Demographic and Health Surveys*

26
27
28 The Egypt Demographic and Health Survey (EDHS) is a national survey that collected data
29
30 pertaining to the health and demographics of a nationally representative sample of the resident
31
32 population of Egypt, including HCV infection[25, 26]. The EDHS that included HCV
33
34 biomarkers was conducted in 2008 and 2014 and used rigorous sampling methods[27]. Details
35
36 on study design, data collection, and laboratory methods can be found in El-Zanaty et al.[25, 26].
37
38 HCV antibody testing was done using a third generation enzyme-linked immunosorbent assay
39
40 (ELISA), the Enzyme Immunoassay Adlatis EIAgen HCV Ab test (Adaltis Inc., Montreal,
41
42 Canada)[25, 26]. All samples that were positive in the ELISA assay and 5% of the negative
43
44 samples were then retested using a more specific assay, the chemiluminescent microplate
45
46 immunoassay (CMIA ARCHITECT plus i1000SR, Abbott Diagnostic, USA)[25, 26]. If a
47
48 sample was positive in both the ELISA and the CMIA testing, it was also tested for current

60

1
2
3 active infection, using real-time, reverse-transcription polymerase chain reaction (RT-qPCR)
4 testing to detect HCV ribonucleic acid (RNA)[25, 26]. Samples were further retested for internal
5 and external quality assurance[25, 26]. Here we restrict our analyses to the HCV antibody
6 results.
7
8
9
10

11
12 Data from the EDHS 2008 and EDHS 2014 were downloaded with permission from Measure
13 DHS[28]. The data can be accessed through application to the DHS Program at
14 <https://dhsprogram.com>. For purposes of this study, the EDHS individual database was merged
15 with the HCV biomarker database, based on established guidelines for managing DHS data[27].
16 All individuals with results for HCV antibody testing were included in the analysis.

26
27 None.
28
29

30 ***Risk score derivation***

31
32 Associations of HCV antibody positivity (seropositivity) with a priori variables that are easy to
33 evaluate in a primary healthcare setting, and that can be included in a risk score, were
34 investigated. These variables included sex (male versus female), age (5-year age strata), and type
35 of place of residence (urban versus rural). Frequency distributions were generated to describe
36 demographic and clinical profiles of tested individuals.
37
38
39
40
41
42
43
44

45 Chi-square tests and univariable logistic regression were implemented to investigate
46 associations. Participants younger than 15 years of age were excluded as this age group was not
47 included in the EDHS 2008 and has low HCV prevalence (Table S1)[6, 29-31]. Odds ratios
48 (ORs), 95% confidence intervals (CIs), and p-values were reported. Covariates with p-values
49 ≤ 0.1 in univariable regression analysis were considered possibly associated with HCV
50
51
52
53
54
55
56
57
58
59
60

1
2
3 seropositivity. These were included in the multivariable analysis for estimation of adjusted ORs
4 (AORs) and associated 95% CIs and p-values. No other forward or backward elimination for
5 variable selection was used. Covariates with p-values ≤ 0.05 in the multivariable model were
6 considered predictors of HCV seropositivity. Univariable and multivariable analyses were
7 adjusted for sampling weights.

8
9
10 A risk score was constructed based on the β -coefficients obtained from the multivariable
11 regression model. β -coefficients were multiplied by a factor of 10 and then rounded to the
12 nearest integer. The total risk score was calculated by adding the individual scores. To keep the
13 score simple enough for use in primary healthcare and other general population settings, we did
14 not consider any interaction terms.

15 16 17 ***Performance and validation of the risk score***

18
19
20 A receiver operating characteristics (ROC) curve was plotted to investigate the performance of
21 the risk score in predicting HCV seropositivity at different score cut-offs. A larger area under the
22 curve (AUC), also called the c-index, indicates better performance of the risk score. The cut-off
23 for the score was determined by maximizing the sum of the sensitivity and specificity.

24
25
26 Sensitivity is the probability that the risk score will yield a positive diagnosis in a subject who is
27 truly HCV antibody-positive. Specificity is the probability that the risk score will yield a
28 negative diagnosis in a subject who is truly HCV antibody-negative.

29
30
31 Performance of the risk score was also investigated by estimating the positive predictive value
32 (PPV) and the negative predictive value (NPV) of the risk score. PPV is the probability that a
33 subject with a positive diagnosis per the risk score is truly HCV antibody-positive. NPV is the
34 probability that a subject with a negative diagnosis per the risk score is truly HCV antibody-
35 negative. The proportion of subjects who have scores greater than or equal to the cut-off of the

3 risk score was estimated to determine the proportion of individuals that need to be biochemically
4 tested for HCV antibodies.
5
6

7
8 To validate the performance of the EDHS 2008 risk score, it was applied to the EDHS 2014 data,
9 providing an independent validation with a dataset different from the one used for its derivation.
10 Performance diagnostics were subsequently assessed. Given the pronounced cohort effect in the
11 epidemiology of HCV infection in Egypt[6, 29-31], the age variable was adjusted to reflect the
12 6-year interval between the surveys. For example, individuals who were 11 years old in 2008
13 would have been 17 years old at the time of the second survey in 2014. The same approach was
14 also used to validate the EDHS 2014 risk score—it was applied to the EDHS 2008 database and
15 performance diagnostics were assessed.

26
27 While the cut-off for the score was determined by maximizing the sum of sensitivity and
28 specificity, this cut-off can be adjusted as needed from a programmatic standpoint to optimize a
29 specific diagnostic metric, such as sensitivity instead of specificity. To illustrate this flexibility,
30 an additional analysis was incorporated featuring a variety of score cut-offs, resulting in diverse
31 values of sensitivity, specificity, PPV, and NPV. Such additional analysis enables program
32 managers and readers to discern the trade-offs among these diagnostic metrics and observe the
33 implications of selecting an alternative programmatic approach, such as prioritizing the
34 optimization of sensitivity over specificity.

52 53 **RESULTS**

54
55
56
57
58
59
60

1
2
3 In the 2008 EDHS, 11,126 individuals 15-59 years of age were tested, of whom 1,571 were
4 antibody-positive[25]. The 2014 EDHS included children 1-14 years of age in addition to adults
5 15-59 years of age[26]. In this latter survey, 26,047 individuals were tested of whom 1,456 were
6 antibody-positive[26].
7
8
9

10
11
12
13 Characteristics of individuals who were tested for HCV antibodies and the proportion of each
14 population stratum that was HCV antibody-positive are shown in Table S1 for both of the EDHS
15 surveys. Results of both surveys were consistent, taking into account the age shift in the national
16 cohort with the passage of 6 years between the EDHS 2008 and EDHS 2014.
17
18
19

20
21
22 HCV seropositivity was strongly associated with sex, age, and place of residence in both national
23 surveys (Table 1 and Table S3). Male sex and rural residence were associated with higher
24 seropositivity. Seropositivity increased rapidly with age.
25
26
27
28
29

30
31 The 2008 and 2014 Egypt Hepatitis C Risk Scores derived using the EDHS 2008 and EDHS
32 2014 data, respectively, are shown in Figure 1. The 2008 Risk Score had a range of 0-41. The
33 2014 Risk Score had a range of 0-53. Both showed similar dependence on sex, age, and type of
34 place of residence. Both demonstrated high and similar AUCs (Figure 2). The AUC was 0.77
35 (95% CI: 0.76-0.78) for the 2008 Risk Score and 0.78 (95% CI: 0.77-0.80) for the 2014 Risk
36 Score. The highest sum of sensitivity and specificity was obtained at a score cut-off value of 22
37 for the 2008 Risk Score and at a cut-off of 34.5 for the 2014 Risk Score.
38
39
40
41
42
43
44
45

46
47 For the 2008 Risk Score, sensitivity was 73.7% (95% CI: 71.5-75.9%), specificity was 68.5%
48 (95% CI: 67.5-69.4%), PPV was 27.8% (95% CI: 26.4-29.2%), and NPV was 94.1% (95% CI:
49 93.5-94.6%) (Table 2). For the 2014 Risk Score, sensitivity was 64.0% (95% CI: 61.5-66.6%),
50 specificity was 78.2% (95% CI: 77.5-78.9%), PPV was 22.2% (95% CI: 20.9-23.5%), and NPV
51 was 95.7% (95% CI: 95.4-96.1%). The proportion of the population 15-59 years of age that
52
53
54
55
56
57
58
59

1
2
3 needed to be biochemically tested for HCV antibodies was 37.2% (95% CI: 36.3-38.1%) using
4 the 2008 Risk Score and 25.5% (95% CI: 24.9-26.2%) using the 2014 Risk Score. Of all people
5
6 with HCV in the EDHS samples, application of this score would have diagnosed (that is
7
8 identified; sensitivity) 73.7% (95% CI: 71.5-75.9%) and 64.0% (95% CI: 61.5-66.6%) of all
9
10 these persons in samples of the EDHS 2008 and 2014, respectively.
11
12
13
14

15 When the 2008 Risk Score was applied to the EDHS 2014 data, the AUC was 0.75 (95% CI:
16
17 0.74-0.77), the sensitivity was 66.1% (95% CI: 63.5-68.6%), and the specificity was 72.3% (95%
18
19 CI: 71.5-73.1%) (Table 2). These performance indicators were similar to the original
20
21 performance indicators generated using the EDHS 2008 data, as well as to the performance
22
23 indicators of the 2014 Risk Score on the EDHS 2014 data. Therefore, this application validates
24
25 this risk score. A similar outcome was found when the 2014 Risk Score was applied to the EDHS
26
27 2008 data, also providing a validation of the 2014 risk score.
28
29
30

31
32 Figure 3 displays the proportion of HCV infections in the population that are diagnosed as a
33
34 function of the proportion of the population that needs to be tested to identify these infections,
35
36 using each of EDHS 2008 and EDHS 2014 data. The figure shows the effect of prioritization of
37
38 testing for those with higher to lower risk score. This provides a demonstration of the utility of
39
40 using the risk score: a large proportion of HCV infections can be diagnosed by testing only a
41
42 small proportion of the population. It is most efficient programmatically to start testing
43
44 individuals with the highest risk score and progressively moving on to those with lower and
45
46 lower risk scores. As testing is expanded to those with low risk scores, the yield in identifying
47
48 more HCV infections is very limited.
49
50
51

52
53 Table 3 illustrates the implications of selecting various score cut-offs, providing insight into the
54
55 trade-offs among different diagnostic metrics, as well as the proportion of the population
56
57
58
59
60

1
2
3 requiring biochemical testing and the proportion of all individuals with HCV identified through
4 the application of this score. For instance, by enhancing the specificity of the risk score, the PPV
5 increases, and the proportion of the population necessitating testing decreases. This reduction in
6 testing requirements helps alleviate costs and streamline the logistics of the test-and-treat
7 program. However, this enhanced program efficiency comes at the expense of lower NPV and
8 sensitivity, implying a smaller proportion of individuals with HCV in the population being
9 identified through the risk score.
10
11
12
13
14
15
16
17
18

19 **DISCUSSION**

20
21 We demonstrated that a risk score that consists of few simple questions that are easy to evaluate
22 in a primary healthcare setting or implemented through a website or an app that helps persons
23 identify their risk of being HCV infected, provides an effective and non-invasive public health
24 tool to identify carriers of HCV infection and to link them to testing and treatment. Biochemical
25 testing methods to identify people with HCV are invasive and time-consuming and require
26 human and financial resources, as well as complex logistics, making them less scalable,
27 particularly in resource-limited settings. In contrast, initial screening using a risk score can be
28 easily administered or self-administered, is non-invasive, and requires minimal resources and
29 logistics. Therefore, HCV risk scores can be an indispensable strategy for the global response to
30 attain the target of HCV elimination as a public health problem by 2030.

46 While the concept of a risk score shares similarities with risk-based testing, which has been
47 implemented in some countries, predominantly in higher-income nations[32-34], the risk score
48 approach transcends mere risk-based testing. It enables a broader application across various
49 settings and situations and can significantly contribute to raising awareness of the infection
50 among the general population. The risk score approach represents a tool that addresses several
51
52
53
54
55
56
57
58
59
60

1
2
3 public health needs simultaneously, extending the application of risk-based testing beyond
4 conventional healthcare settings. Moreover, it entails minimal costs and logistics, making it
5
6 feasible even in resource-limited settings.
7
8
9

10 Remarkably, the risk score, comprising three simple questions, demonstrated considerable
11 diagnostic accuracy, as evidenced by the values of various diagnostic metrics, including AUC,
12 sensitivity, specificity, PPV, and NPV. Of particular note is the high NPV, ensuring that a
13 negative result is highly unlikely to be a false negative, thereby obviating the need for
14
15 individuals with a negative outcome using the score to undergo testing for HCV antibodies. The
16 score also identified 73.7% and 64.0% of all HCV infections in the EDHS 2008 and EDHS 2014
17 samples, respectively. Thus, the score fulfills its objective of facilitating the efficient
18
19 identification of individuals with HCV infection while minimizing the necessity for conducting
20 biochemical testing. This underscores the value of this approach in identifying as many people
21 with HCV as early as possible and initiating treatment before progression to serious clinical
22 disease.

35

36 This approach was demonstrated for Egypt, considering the availability of two EDHS surveys to
37 derive and validate the score. The two scores exhibited comparable structures and diagnostic
38 performances, with minor differences attributed to sampling variation of the same population
39 across two distinct rounds of the EDHS surveys. Each score was validated by applying it to a
40 database other than the one used to derive it. The latter application yielded a diagnostic
41 performance that was comparable to the original diagnostic performance against the database
42 used to originate it. This highlights how a single national survey for HCV infection may be
43 sufficient to develop an effective risk score for this infection, and that can become an integral
44 component of the national response to eliminate HCV infection.

2
3 The approach demonstrated in this study can be applied in other countries, including those in the
4 MENA region. In countries where nationally representative population-based surveys have been
5 conducted, these surveys can serve as the basis for deriving the risk score, as was done in this
6 study. However, only three MENA countries—Egypt, Libya, and Pakistan—have conducted
7 such surveys[25, 26, 35, 36]. For countries where such surveys are not available[10-16], the risk
8 score can still be derived using data from available regional surveys. Alternatively, if regional
9 surveys are not available, the effects of risk factors for infection can be pooled, either in terms of
10 odds ratios or relative risks, using data from analytical studies[37]. These effects can also be
11 derived from meta-regression analyses applied to all available HCV prevalence studies for each
12 country[38-45].

13
14
15 While this study focused on demonstrating the utility of this concept as a public health tool,
16 actual application of this approach to different countries can be enhanced for even higher
17 diagnostic accuracy. One extension could be adding more variables to the score in a manner
18 tailored to the local epidemiology of each country. For instance, province or city of birth and/or
19 current residence, prior exposure to an HCV mode of transmission[37], or history of HCV
20 infection in the family, could be added, among others. Given that the risk of exposure to HCV
21 infection varies immensely by at-risk population type and shows a distinctive hierarchy[46], an
22 additional component to the score could be to integrate the at-risk population type as a
23 variable[41, 46], thereby further enhancing the diagnostic accuracy of the score. Testing
24 strategies, therefore, could be highly efficient in identifying people with HCV at a modest cost.

25
26
27 However, caution must be exercised to prevent the creation of stigma associated with HCV
28 infection or the use of an HCV risk score. For instance, it may not be feasible to include
29 questions about stigmatized behaviors in the MENA context, such as injecting drug use or

1
2
3 specific sexual practices, when the score is applied in general population settings like primary
4 healthcare. However, such questions may be appropriate in other settings, such as voluntary
5 counseling and testing (VCT) centers or outreach efforts by community organizations working
6 with the most at-risk populations[47]. It is important also for the risk score to factor community
7 acceptance in its design and implementation, ensuring it addresses the specific needs of certain
8 groups, such as women of childbearing age in contexts where the risk of HCV vertical
9 transmission is not negligible[48-50].

10
11
12 The application of HCV risk scores can be influenced by programmatic considerations and
13 variations in context. This may necessitate prioritizing specific diagnostic metrics, such as
14 sensitivity over specificity. The approach presented here demonstrates an inherent flexibility of
15 the score, allowing adjustments to address specific programmatic needs, as illustrated by the
16 analysis using different cut-off points (Table 3). However, it is critical to acknowledge the
17 inherent trade-offs between diagnostic metrics. Optimizing one metric, such as sensitivity, will
18 inevitably impact others, like specificity. Therefore, careful consideration is essential to align the
19 score's cut-off with the specific programmatic context and its corresponding needs.

20
21
22 This study has limitations. For ease of use in primary healthcare and more broadly by the public,
23 a risk score has to be simple. Accordingly, it cannot fully represent the complex epidemiology of
24 HCV infection, such as interactions among risk factors. This risk score was derived for Egypt,
25 which may not benefit from this risk score, given that this country has opted for mass testing of
26 its entire population[17]. Derivation of a risk score typically requires at least one round of a
27 population-based survey, ideally at the national level, but many countries may not have such
28 survey data to be able to easily derive a risk score. The risk score was derived for a high-burden
29 country, and utility of this approach still needs to be demonstrated for countries with low HCV

1
2
3 prevalence. Nonetheless, this approach may prove to have higher utility in countries with low
4
5 HCV prevalence than in countries with high HCV prevalence, as HCV epidemiology shows a
6
7 clearer hierarchy in infection exposure risk in countries with concentrated HCV epidemics
8
9 compared to those with generalized HCV epidemics[46].
10
11

12 **Conclusions**

13
14
15 An HCV risk score can be derived using only one round of a population-based survey and offers
16
17 an effective, simple, non-invasive strategy to identify carriers of HCV infection and to link them
18
19 to testing and treatment, at low cost. This public health tool can be implemented and used for
20
21 prioritizing populations for interventions with minimal logistical complexity and cost, especially
22
23 in resource-limited countries.

Type of place of residence								
Urban	1.00		Ref	0	1.00		Ref	0
Rural	2.34 (2.0-2.7)	<0.001	0.85	9	2.15 (1.78-2.59)	<0.001	0.76	8

Abbreviations: aOR, Adjusted odds ratio; CI, Confidence interval; EDHS, Egypt Demographic and Health Survey; HCV, Hepatitis C virus; Ref, Reference category.

[†]The analysis applied the EDHS sampling weights.

^{††}The odds ratio was adjusted for sex, age, and type of place of residence.

[‡]β-coefficients were based on the multivariable regression analysis.

[§]The risk score was calculated by multiplying the β coefficient by 10 and then rounding the result to the nearest integer.

Table 2 Performance of the Egypt Hepatitis C Risk Score

	AUC (95% CI)	Risk score cut- off*	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Proportion needing testing (95% CI)
Derived risk scores							
Risk score derived using the EDHS 2008	0.77 (0.76-0.78)	22.0	73.7 (71.5-75.9)	68.5 (67.5-69.4)	27.8 (26.4-29.2)	94.1 (93.5-94.6)	37.2 (36.3-38.1)
Risk score derived using the EDHS 2014	0.78 (0.77- 0.80)	34.5	64.0 (61.5-66.6)	78.2 (77.5-78.9)	22.2 (20.9-23.5)	95.7 (95.4-96.1)	25.5 (24.9-26.2)
Validation of risk scores							
2008 risk score applied to the EDHS data 2014†	0.75 (0.74-0.77)	22.0	66.1 (63.5-68.6)	72.3 (71.5-73.1)	21.9 (20.6-23.2)	94.8 (94.3-95.2)	31.7 (30.9-32.5)
2014 risk score applied to the EDHS data 2008‡	0.76 (0.74-0.77)	33.5	70.0 (67.5-72.6)	70.0 (69.0-70.9)	24.7 (23.3-26.1)	94.3 (93.7-94.9)	34.6 (33.7-35.5)

Abbreviations: AUC, Area under the curve; EDHS, Egypt Demographic and Health Survey; HCV, Hepatitis C virus; NPV, Negative predictive value; PPV, Positive predictive value.

*The optimal cut-off for the score was determined by maximizing the sum of the sensitivity and specificity.

†The risk score assumes the age of the individuals in 2008 in order to account for the age shift.

‡The risk score assumes the age of the individuals in 2014 in order to account for the age shift.

Table 3 Implications of selecting various score cutoffs on the different diagnostic metrics.

Risk score cut-off	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Proportion needing testing (95% CI)	Proportion that are diagnosed (95% CI)

A.

B.

Abbreviations: EDHS, Egypt Demographic and Health Survey; ROC, receiver operating characteristics. The two scores exhibited comparable structures and diagnostic performances, with minor differences attributed to sampling variation of the same population across two distinct rounds of the EDHS surveys. Details on the derivation of these scores are provided in the Methods and Results sections.

Mathematical formula of the derived Egypt Hepatitis C Risk Score. A) Egypt Hepatitis C Risk Score using the EDHS 2008. B) Egypt Hepatitis C Risk Score using the EDHS 2014.

Proportion of HCV infections in the population that are diagnosed as a function of the proportion of the population that needs to be tested to identify these infections. The figure shows the effect of prioritization of testing for those with higher to lower risk score. A) Using the EDHS 2008 data. B) Using the EDHS 2014 data.

215x279mm (200 x 200 DPI)

Table S1 Characteristics of individuals tested for HCV antibodies in the EDHS 2008 and 2014

Characteristics	EDHS 2008			EDHS 2014		
	Total tested (%)	HCV antibody positive (proportion %)	p-value	Total tested (%)	HCV antibody positive (proportion %)	p-value
No	11,126	1,571		26,047	1,456	
Sex						
Female	6,052 (54.4)	711 (11.8)	<0.001	13,707 (52.6)	660 (4.8)	<0.001
Male	5,074 (45.6)	860 (17.0)		12,340 (47.4)	796 (6.4)	
Age group (years)						
1-4	-	-	-	3,282 (12.6)	10 (0.3)	
5-9	-	-	-	3,601 (13.8)	10 (0.3)	
10-14	-	-	-	3,161 (12.1)	23 (0.7)	
15-19	2,000 (18.0)	82 (4.1)		2,568 (9.9)	30 (1.2)	
20-24	1,837 (16.5)	91 (5.0)		1,976 (7.6)	54 (2.7)	
25-29	1,520 (13.7)	92 (6.1)		2,358 (9.0)	88 (2.7)	
30-34	1,244 (11.2)	133 (10.7)		2,076 (8.0)	114 (5.5)	<0.001
35-39	1,141 (10.3)	147 (12.9)	<0.001	1,853 (7.1)	130 (7.0)	
40-44	1,069 (9.6)	238 (22.3)			1,468 (5.6)	146 (10.0)
45-49	939 (8.4)	275 (29.3)		1,380 (5.3)	208 (15.1)	
50-54	728 (6.5)	272 (37.4)		1,334 (5.1)	337 (25.3)	
55-59	648 (5.8)	241 (37.2)		990 (3.8)	306 (30.9)	
Type of place of residence						
Urban	4,448 (40.0)	442 (9.9)	<0.001	11,955 (45.9)	546 (4.6)	<0.001
Rural	6,678 (60.0)	1,129 (16.9)		14,092 (54.1)	910 (6.5)	

Abbreviations: EDHS, Egypt Demographic and Health Survey; HCV, Hepatitis C virus

Table S2 STROBE checklist for cross-sectional studies

	Item No	Recommendation	Main Text Page No
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	Abstract page 2
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	Abstract page 2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	Introduction page 4
Objectives	3	State specific objectives, including any prespecified hypotheses	Introduction page 5
Methods			
Study design	4	Present key elements of study design early in the paper	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score') pages 5-8
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	Methods ('Egypt Demographic and Health Surveys') pages 5-6
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	Methods ('Egypt Demographic and Health Surveys') pages 5-6
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score') pages 5-8 & Table S1 page 1
Data sources/measurement	8	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score') pages 5-8 & Table 1 & Table 3 & Tables S2-S3 pages 3-4 & Figures 1-2
Bias	9	Describe any efforts to address potential sources of bias	Methods ('Risk score derivation' & 'Performance and validation of the risk score') pages 6-8 & Table 2 & Figures 1-2
Study size	10	Explain how the study size was arrived at	Not applicable, see Methods ('Egypt Demographic and Health Surveys') pages 5-6
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation' & 'Performance and validation of the risk score') pages 5-8 & Tables 1-3 & Table S3
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	Methods ('Risk score derivation' & 'Performance and validation of the risk score') pages 5-8
		(b) Describe any methods used to examine subgroups and interactions	Not applicable, see Methods ('Risk score derivation' & 'Performance and validation of the risk score') pages 6-8
		(c) Explain how missing data were addressed	Not applicable, see Methods ('Egypt Demographic and Health Surveys', 'Risk score derivation') pages 5-8
		(d) If applicable, describe analytical methods taking account of sampling strategy	Not applicable
		(e) Describe any sensitivity analyses	Not applicable
Results			
Participants	13	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed (b) Give reasons for non-participation at each stage (c) Consider use of a flow diagram	Table 1 & Tables S1 & Table S3
Descriptive data	14	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Table 1 & Table S1 & Table S3 & Figure S1
		(b) Indicate number of participants with missing data for each variable of interest	Not applicable, see Methods ('Egypt Demographic and Health Surveys') pages 5-6
Outcome data	15	Report numbers of outcome events or summary measures	Results pages 8-11 , Figures 1-2, Figure S1, Tables 1-3 & Table S1
Main results	16	(a) Give unadjusted estimates and, if applicable,	Table 1 & Table S3

		confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	
		(b) Report category boundaries when continuous variables were categorized	Tables 1-3 & Table S1 & Table S3
		© If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	Tables 2-3 & Table S3 & Figure S1
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	Results pages 8-11 & Table 2 & Figure 2
Discussion			
Key results	18	Summarise key results with reference to study objectives	Discussion pages 11-12 , paragraphs 1-3
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	Discussion, paragraph 9 page 14
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	Discussion, paragraphs 4-6 pages 12-13
Generalisability	21	Discuss the generalisability (external validity) of the study results	Discussion, paragraphs 7-8 pages 13-14
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	Acknowledgements page 16

Table S3 Results of univariable and multivariable regression analyses to derive the Egypt Hepatitis C Risk Score using data from EDHS 2008 and EDHS 2014

Abbreviations: aOR, Adjusted odds ratio; CI, Confidence interval; EDHS, Egypt Demographic and Health Survey; HCV, Hepatitis C virus; OR, Odds ratio; Ref, Reference category.

*The analysis applied the EDHS sampling weights.

†The odds ratio was adjusted for sex, age, and type of place of residence.

‡β-coefficients were based on the multivariable regression analysis.

§The risk score was calculated by multiplying the β coefficient by 10 and then rounding the result to the nearest integer.
