## 1049 Supplemental Methods

### 1050 Trait TPC model specifications

1051 In the following models, the subscript  $i$  denotes values corresponding to each individual-  
 1052 level observation. The temperature-dependent mean trait value ( $\mu_i$ ) is defined by either a quadratic  
 1053 or Brière function. The inequalities are used to restrict the trait values to zero where the  
 1054 temperature is greater than  $T_{max}$  or less than  $T_{min}$ . The other parameters ( $\tau$ ,  $s$ ,  $r$ , and  $p$ ) are used to  
 1055 define the relevant probability distribution and relate it to  $\mu_i$ . The corresponding code can be found  
 1056 in the project GitHub repository.

1057

1058 *Normal likelihood truncated at 0 with Brière function for bite rate*

1059  $\text{bite rate}_i \sim \text{normal}(\mu_i, \tau) \text{ truncated}(0,)$

1060  $\mu_i = cT(T-T_{min})(T_{max}-T)^{1/2}(T > T_{min})(T < T_{max})$

1061

1062 *Negative binomial likelihood with quadratic function for lifespan*

1063  $\text{lifespan}_i \sim \text{gamma}(s_i, r)$

1064  $s_i = r * \mu_i$

1065  $\mu_i = -c(T-T_{min})(T-T_{max})(T > T_{min})(T < T_{max})$

1066

1067 *Gamma likelihood with quadratic function for lifetime egg production*

1068  $\text{egg}_i \sim \text{negative binomial}(p_i, r)$

1069  $p_i = r / (r + \mu_i)$

1070  $\mu_i = -c(T-T_{min})(T-T_{max})(T > T_{min})(T < T_{max})$

1071 **Parton-Logan model for diurnal temperature fluctuations**

1072 To simulate a stereotypical profile of temperature fluctuation around a temperature mean  
 1073 through the course of a 24-hour period, we programmed our incubator using a Parton-Logan model  
 1074 <sup>66</sup> to run 10 daily temperature fluctuation profiles. Profiles fluctuated at the hourly scale with a  
 1075 diurnal temperature range (DTR) of either 9 or 12°C around five mean temperatures (16, 20, 24,  
 1076 28, or 32°C; **Figure 1**). Parton-Logan models assume a sinusoidal relationship with temperature  
 1077 during the day ( $T_{day}$ ) that peaks at a maximum temperature ( $T_{max}$ ), followed by an exponential  
 1078 decay during the night ( $T_{night}$ ; **Equation S1**) that asymptotes at the minimum temperature ( $T_{min}$ ).

$$1079 \quad T_{day}(m) = T_{min} + (T_{max} - T_{min}) \sin\left(\frac{\pi m}{Y + 2a}\right) \quad \text{Eq. S1A}$$

$$1080 \quad T_{night}(n) = \frac{T_{min} - T_{sunset} \cdot e^{\frac{-Z}{\tau}} + (T_{sunset} - T_{min})e^{\frac{-n}{\tau}}}{1 - e^{\frac{-Z}{\tau}}} \quad \text{Eq. S1B}$$

1081 Note these definitions of  $T_{min}$  and  $T_{max}$  differ from those used elsewhere in the paper, which  
 1082 describe the thermal limits of a TPC. For a given temperature regime,  $T_{sunset}$  is calculated as the  
 1083 final temperature predicted by **Equation S1A** and then used to parameterize **Equation S1B**. We  
 1084 assumed a day length ( $Y$ ) and night length ( $Z$ ) of 12 hours each, such that the ratio of light to dark  
 1085 hours was 12:12. The day constant ( $a = 1.5$ ) sets the period of the sine wave and thus determines  
 1086 the timing of  $T_{max}$ , (where larger  $a$  delays  $T_{max}$ ), while the night constant ( $\tau = 4$ ) adjusts the timing  
 1087 of the exponential decay (where smaller  $\tau$  results in a faster decay). The inputs  $m$  and  $n$ , denote the  
 1088 number of hours after sunrise and sunset, respectively, are used to calculate the desired sequence  
 1089 of hourly temperatures over time. Finally, the mean of  $T_{min}$  and  $T_{max}$  do not exactly equal the  
 1090 mean daily temperature predicted by this model.

1091 With this model, the mean daily temperature ( $T_{mean}$ ) is close but not exactly equal to the  
1092 mean of  $T_{min}$  and  $T_{max}$ . Thus, in order to parameterize the model for a specific mean temperature,  
1093 you cannot determine  $T_{min}$  and  $T_{max}$  simply by subtracting or adding (respectively) half the DTR to  
1094 the desired  $T_{mean}$  – a small corrective factor ( $c$ ) must also be used. This corrective factor is scaled  
1095 by the DTR and is specific to a given day length. For a 12:12 day:night cycle,  $c = 0.0575824$  and  
1096 is used according to:

$$1097 \quad T_{min} = T_{mean} - \frac{DTR}{2} - c \cdot DTR \quad \text{Eq. S2A}$$

$$1098 \quad T_{max} = T_{mean} + \frac{DTR}{2} - c \cdot DTR \quad \text{Eq. S2B}$$
