Experimental Methods

Characterization

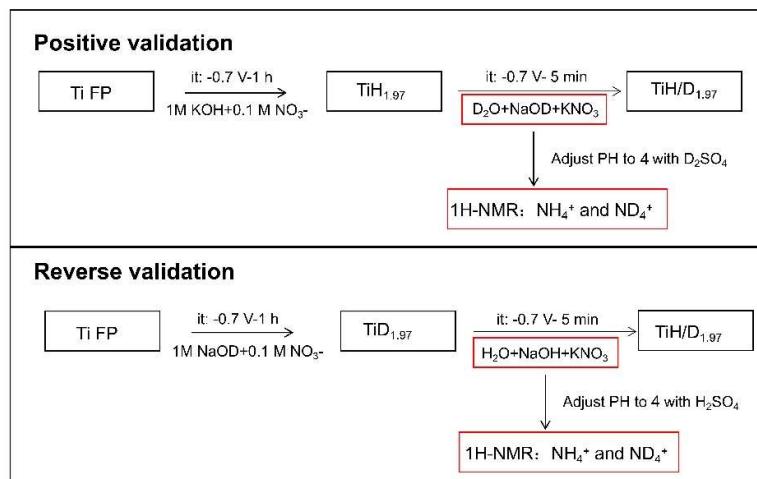

The crystal structure of the prepared electrocatalysts were determined by Smartlabse (RIGAKU) X-ray diffractometer (XRD) with Cu K α radiation ($\lambda=0.15406$ nm). The microstructure and morphology were clarified by Regulus 8100 (HITACHI) Field Emission Scanning Electron Microscope (FESEM) and JEM-2100F (JEOL) transmission electron microscope (TEM) at an acceleration voltage of 200 kV. High-angle annular dark-field scanning TEM (HAADF-STEM) image images were taken on an ARM-200CF (JEOL, Tokyo, Japan) transmission electron microscope, operating at 200 kV, to analyze the microzone structure. A UV-vis spectrophotometer (EVOLUTION 201, Thermo Scientific Corporation) measurements in the range of 200-1000 nm. ^1H -NMR measurements were performed on Bruker AVANCE III HD 600 MHz Nuclear Magnetic Resonance System (NMR-600). X-ray absorption fine structure (XAFS) measurements of the Ti K-edge in transmission mode for Ti foil and titanium hydride powder were performed at Beijing Synchrotron Radiation Facility (BL1W1B station), China.

Isotope labeled active hydrogen transfer in NIRR.

Positive validation method for the participation of lattice hydrogen in hydrogenation reactions in titanium hydride. In an H-type electrolysis cell, a $\text{TiH}_{1.97}/\text{Ti}$ catalyst was prepared. A D_2O solution containing 1 M NaOD and 0.1 M KNO_3 was used as the electrolyte for NIRR. Both the Ti FP and the synthesized $\text{TiH}_{1.97}/\text{Ti}$ electrode were rinsed with D_2O for 10 minutes and dried at 250 °C under argon for 24 h to remove H_2O . NIRR was conducted at -0.7 V vs. RHE for 5 min, after which 10 mL of

electrolyte was taken out and adjusted to pH = 4 with 2 M D₂SO₄, and the resulting products, NH₃ and ND₃, were explored using ¹H NMR.

Reverse validation method for the participation of lattice hydrogen in hydrogenation reactions in titanium hydride. In an H-type electrolysis cell, a TiD_{1.97}/Ti catalyst was prepared by cathodic electrochemical reconstruction for 30 min in a D₂O + NaOD + NO₃⁻ solution. Subsequently, an H₂O solution containing 1 M NaOH and 0.1 M KNO₃ was used as the electrolyte for NIRR. NIRR was conducted at -0.7 V vs. RHE for 5 min, after which 10 mL of electrolyte was taken out and adjusted to pH = 4 with 2 M D₂SO₄, and the resulting products, NH₃ and ND₃, were explored using ¹H NMR. The flow diagram for positive and reverse validation as flow:

Determination of ion concentration

The ultraviolet-visible (UV-Vis) spectrophotometer was used to detect the ion concentration of pre-test and post-test electrolytes after diluting to appropriate concentration to match the range of calibration curves (Fig. S10). The specific detection methods were described as follows.

Determination of ammonia-N

Ammonia-N was determined using salicylic acid-potassium sodium tartrate chromogenic reagent as the color reagent. First, a certain amount of electrolyte was

taken out from the electrolytic cell and diluted to 5 mL to detection range. Next, 0.5 mL salicylic acid-potassium sodium tartrate chromogenic reagent was added and mixed thoroughly, then 0.05 mL sodium nitroprusside and 0.05 mL sodium hypochlorite solution were put into the solution. The absorption intensity at a wavelength of 655 nm was recorded after sitting for 1 h. The concentration-absorbance curve was calibrated using a series of standard ammonium chloride solutions and the ammonium chloride crystal was dried at 105 °C for 2 h in advance.

Determination of nitrate-N

Firstly, a certain amount of electrolyte was taken out from the electrolytic cell and diluted to 5 mL to detection range. Then, 0.1 mL 1 M HCl and 0.01 mL 0.8 wt% sulfamic acid solution were added into the aforementioned solution. The absorption spectrum was measured using an UV-Vis spectrophotometer and the absorption intensities at a wavelength of 220 nm were recorded. The final absorbance value was calculated by this equation: $A = A_{220nm}$. The concentration-absorbance curve was calibrated using a series of standard potassium nitrate solutions and the potassium nitrate crystal was dried at 105-110 °C for 2 h in advance.

Determination of nitrite-N

A mixture of p-aminobenzene sulfonamide (4 g), N-(1-Naphthyl) ethylenediamine dihydrochloride (0.2 g), ultrapure water (50 mL) and phosphoric acid (10 mL, $\rho=1.70$ g mL^{-1}) was used as a color reagent. A certain amount of electrolyte was taken out from the electrolytic cell and diluted to 10 mL to detection range. Next, 0.1 mL color reagent was added into the aforementioned 10 mL solution and mixed uniformly, and the absorption intensity at a wavelength of 540 nm was recorded after sitting for 20 min. The concentration-absorbance curve was calibrated using a series of standard sodium nitrite solutions.

Isotope Labeling Experiments.

99.21% K¹⁵NO₃ was used as the feeding N-source to perform the isotopic labeling nitrate reduction experiments to clarify the source of ammonia. 1 M KOH was used as electrolyte and K¹⁵NO₃ with a concentration of 0.1 M ¹⁵NO₃⁻-¹⁵N was added into the cathode compartment as the reactant. After electroreduction, electrolyte with obtained ¹⁵NH₄⁺-¹⁵N was taken out and the pH value was adjusted to be weak acid with 2 M H₂SO₄ for further analysis by ¹H NMR (600 MHz) with external standards of maleic acid.

Computational details

All the spin-polarized density functional theory calculations were performed by using the Vienna ab initio Simulation Program (VASP)^{1, 2}. The generalized gradient approximation (GGA) in the Perdew-Burke-Ernzerhof (PBE) form and a cutoff energy of 500 eV for planewave basis set were adopted³. A 3 × 3 × 1 Monkhorst-Pack grid was used for sampling the Brillouin zones at structure optimization⁴. The ion-electron interactions were described by the projector augmented wave (PAW) method⁵. A Gaussian smearing of 0.05 eV to the orbital occupation was applied during the geometry optimization and for the total energy computations. The convergence criteria of structure optimization were choose as the maximum force on each atom less than 0.02 eV/Å with an energy change less than 1 × 10⁻⁵ eV. Periodic slabs with 2 × 3 and 2 × 2 supercell were applied to model the catalyst surfaces, respectively, and a sufficient vacuum of 18 Å was considered in the orthogonal direction to avoid periodic interaction. The DFT-D3 semiempirical correction was described via Grimme's scheme method⁶. According to previously reports, the effective strength parameter ($U_{eff} = U - J$) of the Hubbard on-site Coulomb correlation were set at 2.58 eV for Ti element⁷.

The implicit solvent model (VASPsol) was adopted since the reaction normally takes place in an aqueous solution⁸. To calculate the kinetic energy barrier of chemical reactions, the climbing image nudged elastic band (CI-NEB) method with 6 images was used to search for the transition states (vibrational frequencies were evaluated to confirm minima and transition states), in which all of the force components perpendicular to the tangent of the reaction path were relaxed to be less than 0.05 eV/Å⁹.

The Gibbs free energy change (ΔG) for each elemental step is defined as^{10, 11}:

$$\Delta G = \Delta E + \Delta ZPE - T\Delta S + \Delta G_U + \Delta G_{pH} \quad (1)$$

where ΔE and ΔZPE are the adsorption energy based on density functional theory calculations and the zero-point energy correction, respectively. T , ΔS , U , and ΔG_{pH} represent the temperature ($T = 298$ K), the entropy change, the applied electrode potential, and the free energy correction of the pH ($pH = 0$), respectively. In addition, the atomic coordinates of the optimized computational models had been provided as as a separate supporting file named as supplementary data 1.

TiH_{1.97}/Ti

Fig. S3 The digital images of Ti FP and TiH_{1.97}/Ti.

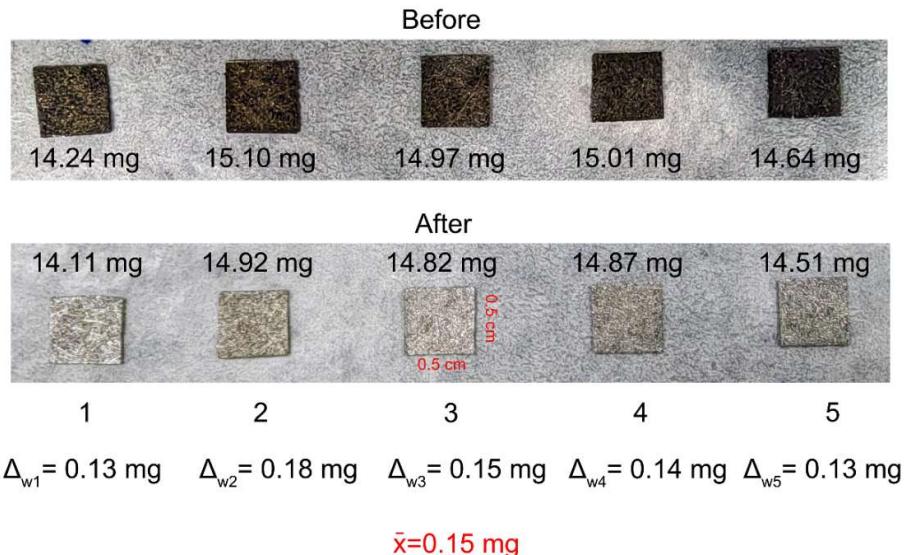

Fig. S4 Weighing the difference in mass before and after the reaction with 0.1 M HCl.

Note: We used the strong oxidizing agent (HCl: 0.1 M) to undergo a chemical reaction with the electrode ($\text{TiH}_{1.97}/\text{Ti}$). By weighing the difference in mass before and after the reaction (Fig. S4), we could obtain the weight of the titanium hydride loaded on the electrode (data from five sets of measurements were taken and the average was calculated). This was because metal hydrides are highly reactive with hydrochloric acid, while metallic titanium did not react with HCl, so the weight loss on the electrode belongs to titanium hydride. Through calculation, we obtained a titanium hydride loading of 0.6 mg cm^{-2} on the electrodes.

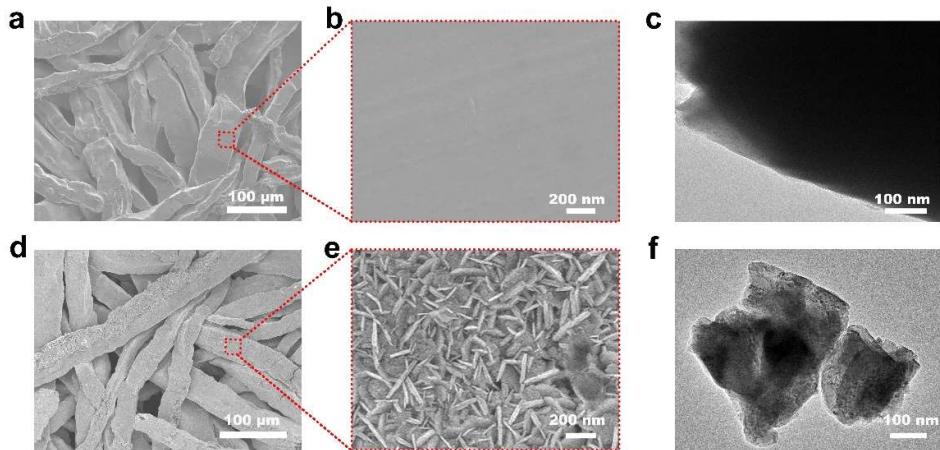

Fig. S14 (a, b) SEM and (c) TEM images of the original Ti FP. (d, e) SEM and (f) TEM images of the titanium hydride after electrocatalysis.

Note: Based on the SEM images in Fig. S14a and the locally magnified image (Fig. S14b), it could be seen that the Ti FP were formed by the intertwined and interwoven titanium fibers, and the diameter of a single titanium fiber was approximately 60 μm . The surface of the titanium fibers was smooth and free of any impurities. The TEM image (Fig. S14c) also showed the smooth surface and solid structure of the titanium fibers. After NIRR treatment, $\text{TiH}_{1.97}/\text{Ti}$ still maintained the mesh-like structure of the titanium fiber paper (Fig. S14d), and the titanium hydride nanosheets on the surface did not undergo significant morphological changes compared to the pre-electrocatalysis (Fig. S14e and Fig. 1g). The TEM image (Fig. S14f) also showed that the surface of the nanosheets remained smooth after electrochemical catalysis, further indicating the good structural stability of the catalyst.

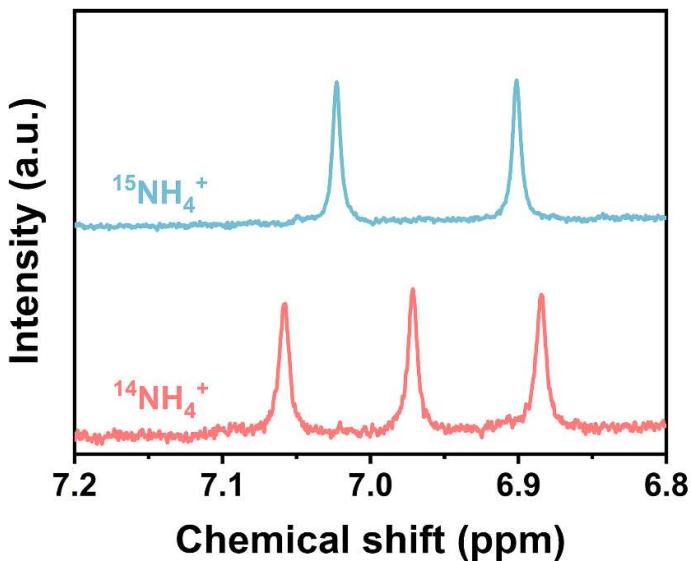

Fig. S21 ^1H NMR spectra of the electrolyte after the NIRR using $^{15}\text{NO}_3^-$ as the feedstock.

Note: To confirm that the isotopic labeling experiments were conducted using $^{15}\text{NO}_3^-$ and $^{14}\text{NO}_3^-$ as reactants, respectively. The $^{15}\text{NH}_3$ signal, a classic marker, was detected at $\delta = 6.90$ and 7.02 ppm in the ^1H nuclear magnetic resonance (NMR) spectrum with $^{15}\text{NO}_3^-$ as the feedstock (Fig. S21), showing no difference compared to the ^1H NMR spectrum of $(^{15}\text{NH}_4)_2\text{SO}_4$. Similarly, using $^{14}\text{NO}_3^-$ as the reactant in the electrolyte yielded consistent detection results with that of $(^{14}\text{NH}_4)_2\text{SO}_4$ via ^1H NMR analysis, illustrating that the NH_3 was generated entirely by NIRR¹².

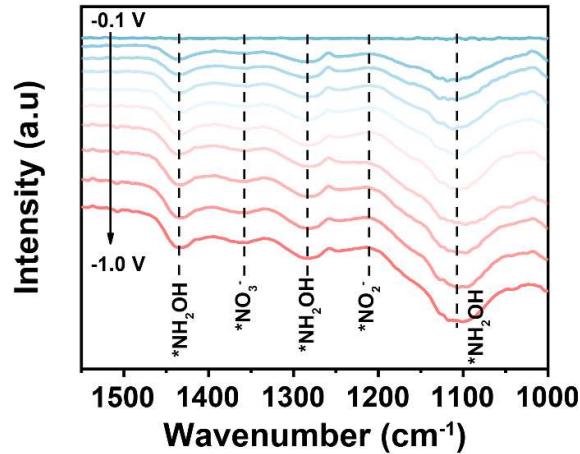

Fig. S24 In-situ ATR FTIR spectra of different intermediates in NIRR pathway.

Note: We employed in-situ Attenuated Total Reflection Fourier Transform Infrared Spectroscopy (ATR-FTIR) to monitor intermediates adsorbed on the titanium hydride. As shown in Fig. S24, five distinct absorption bands were observed in the spectra of $\text{TiH}_{1.97}$ ^{13, 14}. Initially, as the potential increased, the absorption bands at 1354 cm^{-1} , corresponding to the symmetric and asymmetric N-O stretching of NO_3^- , indicated the consumption of NO_3^- . Concurrently, the downward band at 1236 cm^{-1} was attributed to the N-O antisymmetric stretching vibration of NO_2^- , signifying NO_2^- formation from the reduction of NO_3^- . With further negative shift in potential, an intermediate around 1110 cm^{-1} was attributed to the N-O stretching vibration of hydroxylamine (NH_2OH), a crucial intermediate for NH_3 formation. The presence of the characteristic peak of the $-\text{NH}_2$ wagging mode at 1440 cm^{-1} confirmed the formation of NH_3 ¹⁵.

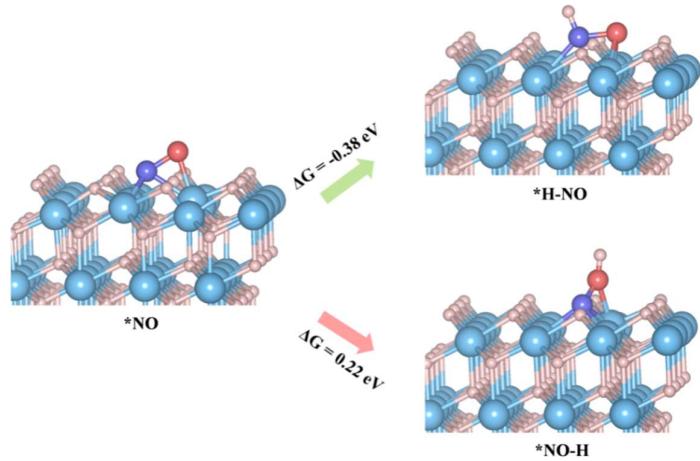

Fig. S31 Calculated reaction free energy from ***NO** to ***NO-H** and ***H-NO**. The light blue, purple, red and pink spheres represent Ti, N, O, and H atoms, respectively.

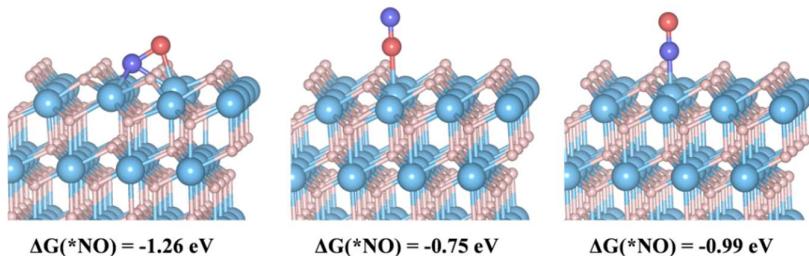

Fig. S32 Different adsorption configurations and corresponding adsorption free energies of NO on $\text{TiH}_{1.97}$. The light blue, purple, red and pink spheres represent Ti, N, O, and H atoms, respectively.

Note: As shown in Fig. S31, it could be found that the reaction free energy from $^*\text{NO}$ to $^*\text{NO-H}$ (0.22 eV) was higher than that from $^*\text{NO}$ to $^*\text{H-NO}$ (-0.38 eV), indicating the priority of N-terminal of NO during hydrogenation process. In addition, the different adsorption configurations of NO on $\text{TiH}_{1.97}$ were tested, as shown in Fig. S32. By comparing the adsorption free energy of NO, we could conclude that NO tends to adsorb on $\text{TiH}_{1.97}$ in a lying mode with ΔG ($^*\text{NO}$) of -1.26 eV.

Supplementary Tables

Table S1. Data obtained by fitting Nyquist plots.

Sample	R _s (ohm)	R _p (ohm)	CPE ₁ (F cm ⁻²)	R _{ct} (ohm)	CPE ₂ (F cm ⁻²)
TiH _{1.97} +NO ₃ ⁻	1.55	0.23	0.993	0.82	1.028
TiH _{1.97}	1.803	0.07	1.115	4.751	0.865
Ti+NO ₃ ⁻	1.998	0.252	1.084	1.759	1.047
Ti	2.13	0.174	1.047	19.97	0.823

Table S2. Structural parameters of Ti, TiH_{1.97} and TiH₂ extracted from the EXAFS fitting.

Sample	Scattering path	CN	R(Å)	$\sigma^2/\text{\AA}^2$	R factor
TiH _{1.97}	Ti-Ti1.1	12	3.13	0.006	0.011
TiH ₂	Ti-Ti1.1	12	3.14	0.004	0.005
Ti fiol	Ti-Ti1.1	6	2.90	0.012	0.013

The S_0^2 was fixed as 0.7. The interatomic distances (R) and coordination numbers (CN). The CN was the coordination number; R was the half path length of the path, for a single scattering path, it was the inter-atomic distance. σ^2 was the mean square variation in path length, this parameter encapsulates both static and thermal disorder. ΔE_0 was an adjustment to the E_0 used to evaluate the wavenumber of the theory, it is useful to think of ΔE as the parameter which aligns the energy grids of the data and the theory. R factor was used to indicate the accuracy of the fitting. The fitted ranges for k and R spaces were selected to be k=3-12.4 Å⁻¹ with R=1.5-3.5 Å (k³-weighted).
