SUPPLEMENTARY METHODS

Composite exposure

A composite measure was created (i.e., joint/pipe years) to assess a multifaceted exposure including duration, frequency, and quantity of cannabis smoking. Joint/pipe years was calculated using the low end, midpoint, and high end for each categorical response to "During the time that you smoked marijuana or hashish regularly, how often would you usually smoke it?". For the midpoint, joint/pipe years was calculated as follows: (midpoint value of each categorical response to "During the time that you smoked marijuana or hashish regularly, how often would you usually smoke it?" x 12 months/year x "On the days that you smoked marijuana or hashish, how many joints or pipes would you usually smoke?" x years of regular smoking) / days per year (For example: (6 times per month x 12 months/year x 3 joints/pipes per day x 10 years of regular smoking) / 365.25 = 5.9 joint/pipe years. Midpoint values were determined as follows: "Missing"=0, "once per month" =1, "2-3 time per month" =2.5, "4-8 times per month (about 1-2 times per week)"=6, "9-24 times per month (about 3-5 times per week)"=16.5, "25-30 times per month (about one or more times per day)" =27.5.

Covariates

Sex, race/ethnicity, household income and educational attainment were assessed using standard questionnaires at the baseline visit.(1) Age, physical activity, cigarette smoking, current alcohol use, diabetes status, and medication use were assessed using standard questionnaires at Exam 6.

Physical activity was reported as the total of moderate and vigorous activity, measured in MET-min/week from Monday through Sunday. Values exceeding the 99th percentile (n=31) were deemed unrealistic and were set equal to the 99th percentile (27,870 MET-min/week).

Interaction analysis

Multiplicative, first-order interactions were constructed in the multivariable adjusted regression models for variables designated a priori: age (59-69, 70-80, > 80), race/ethnicity (Non-Hispanic White, Non-Hispanic Black, Hispanic, Chinese), sex (male, female), and cigarette smoking status (current, past, never). Interaction terms were considered significant in the final multivariable adjusted model if $p < 0.10$.

p	0.01	<.01	<.01	0.82	0.43	0.33	0.85	0.52	0.98	0.73	0.72	0.83

All comparisons include participants who reported no history of regular smoking.

Model 1: age, gender, race/ethnicity, HH income.

Model 2: Model 1 plus alcohol and cigarette use, physical activity

Model 3 : Model 2 plus BMI, total cholesterol to HDL cholesterol ratio, FBG, antihypertensive, antilipidemic, and antidiabetic medications.

Abbreviations: CI, confidence interval; HH, household; BMI, body mass index; HDL, high density lipoprotein; FBG, fasting blood glucose

p-values for multiple comparisons have been adjusted using Tukey's method.

The largest significant p value was reported when multiple significant differences were found.

Bold = p < 0.05

Low end, midpoint, and high end of each categorical response to "During the time that you smoked marijuana or hashish regularly, how often would you usually smoke it?".

Model 1: age, gender, race/ethnicity, education, HH income.

Model 2: Model 1 plus alcohol and cigarette use, physical activity

Model 3 : Model 2 plus BMI, total cholesterol to HDL cholesterol ratio, FBG, antihypertensive, antilipidemic, and antidiabetic medications.

Abbreviations: CI, confidence interval; HH, household; BMI, body mass index; HDL, high density lipoprotein; FBG, fasting blood glucose

Bold = p < 0.05

Table 5 (Supplementary) – Adjusted mean blood pressure and 95% confidence intervals among participants denying MI or stroke, by cannabis smoking status (subgroup, n=3,105)

Characteristic	Model 3
