## ***1. Genotyping technology and quality control of genotyping***

DNA of PANDoRA samples was isolated from whole blood using QIAamp DNA extraction kit (Qiagen, California, USA) and distributed in 384-well plates for genotyping. For quality control, 8% of the samples were randomly replicated throughout the plates, and no-template controls were included in each plate. Genotyping was performed using KASP assay. A QuantStudio 5 instrument and QuantStudio software (Applied Biosystems) were used to detect the genotypes. After genotyping, deviation from HWE distribution was assessed in controls, considering the overall population and dividing by the country of origin of the samples.

## ***2. Imputation and quality controls of imputation***

The genotypes of PDAC cases and controls were downloaded from the database of Genotypes and Phenotypes (dbGaP; study accession nos. phs000206.v5.p3 and phs000648.v1.p1; project reference no. 12644). Genotyping procedures, quality control and data collection details of these studies have been previously described in the original publications[1-4]. After downloading the datasets, we carried out quality controls (QCs) and imputation. The QCs were performed prior to the imputation and included: removal of individuals with gender mismatches, call rate < 0.98, minimal or excessive heterozygosity (> 3 SDs from the mean) or cryptic relatedness (PI\_HAT > 0.2) and exclusion of SNPs with minor allele frequency (MAF) < 0.01, call rate < 0.98 or evidence for violations of HWE ( $p < 1 \times 10^{-6}$ ). The genotypes were phased using SHAPEIT v2 software and the imputation was performed, separately for each dataset, using the Michigan Imputation Server (<https://imputationserver.sph.umich.edu>), and the Haplotype Reference Consortium (HRC) as reference, and merged using PLINK 2.0 software<sup>51</sup>. Afterwards the SNPs with completion rate and call-rate < 98%, a minor allele frequency (MAF) < 0.01, evidence for violations of HWE ( $p < 1 \times 10^{-5}$ )

and low-quality imputation score (INFO score < 0.7) were discarded, leaving 7,509,345 SNPs in the final dataset.

### ***3. PANDoRA ethnic composition***

The PANDoRA consortium has been extensively described elsewhere[5]. Briefly, it consists of a multicentric study conducted in 10 European countries (Italy, Greece, Germany, Netherlands, Denmark, Czech Republic, Hungary, Poland, Lithuania and United Kingdom), and Brazil. Cases had a confirmed diagnosis of PDAC and data on age at diagnosis, sex and country of origin was retrospectively collected for each patient. Controls were selected from blood donors, the general population and hospitalised subjects without oncological diseases. In addition to PANDoRA subjects, the genotypes of British and Dutch controls from the European Prospective Investigation into Cancer and Nutrition (EPIC)[6, 7], a prospective cohort study with 519,978 participants (aged 35–70 years) from ten European countries, and German controls from Epidemiologische Studie zu Chancen der Verhütung, Früherkennung und optimierten Therapie chronischer Erkrankungen in der älteren Bevölkerung (ESTHER)[8], a cohort study that includes 9,961 German people aged between 50 and 74 years, were included.

### ***4. Supplementary Table 1 (uploaded as separated Excel file due to its large size).***

### ***5. Supplementary Table 2 (uploaded as separated Excel file due to its large size).***

**6. Supplementary Table 3.**

**Supplementary Table 3.** Cell types analysed either in whole blood or peripheral mononuclear blood cells.
