31 1. Materials and methods

32 1.1 Sample preparation for single-cell RNA-seq

33 One portion of tissue from twin female goats (n=2/group) was minced into 2-3 mm pieces and 34 then incubated in a 37 °C water bath with multiple enzymes (1.0 mg/mL collagenase IV, 2.0 mg/mL 35 dispase, and 50 U/mL DNase I) at $100 \times rpm$ for 30 min. We added 10% FBS to stop the digestion 36 process, followed by a filtration step using 70-µm and 30-µm Smart Strainer (Miltenyi Biotec, Bergisch Gladbach, Germany). Then the supernatant was discarded, and cells were collected (400 37 \times g for 7 min at 12 °C). To remove red blood cells, dead cells, and cellular debris from the dissociated 38 39 cells, we used Red Blood Cell Lysis Buffer and the MACS Dead Cell Removal Kit (Miltenyi Biotec, 40 Bergisch Gladbach, Germany) as per the manufacturer's direction. After that, the total cell count 41 and viability were checked using a hemocytometer (Thermo Fisher Scientific) and trypan blue 42 (Thermo Fisher Scientific, Waltham, MA, USA), respectively. Finally, single-cell suspensions without cell debris and having greater than 90% viability were passed to the subsequent analysis. 43 44 The appropriate volume was calculated for a target capture of 8000 cells, and then the cells were 45 further diluted to a user guide concentration (700-1200 cells/ μ L) with 1× PBS with 0.04% BSA for 46 10x Genomics sequencing. 47 1.2 Single-cell RNA-seq library construction and sequencing Briefly, to obtain single-cell gel bead-in-emulsions (GEM), we loaded the cellular suspensions 48

49 onto the latest 10x Chromium[™] Single Cell 3' Solution system. Then, we used the 10x Genomics 50 3' Reagent Kits v3 and Agilent Bioanalyzer High Sensitivity chip to construct and check the quality 51 of the scRNA-seq libraries, respectively. To reduce the batch effects of samples, we constructed the 52 libraries using the exact versions of kits as per the manufacturer's protocols. The libraries were 53 sequenced on the same Illumina NovaSeq 6000 sequencing system in a 150-bp paired-ended manner 54 by LC-Bio Technology Co., Ltd. (Hangzhou, China) at a minimum depth of 20,000 reads per cell.

55 1.3 Single-cell RNA-seq data analysis

56 The Illumina bcl2fastq software (version 5.01) were applied to convert the sequencing results 57 in to FASTQ files. Raw data were demultiplexed, barcode and mapped to the goat reference genome (https://www.ncbi.nlm.nih.gov/assembly/GCF 001704415.1/) using the Cell Ranger package 58 (version 3.1.0). Primary alignment to the Cell Ranger showed 95% valid barcodes and 54.30% 59 60 sequencing saturation. Feature-barcode raw digital gene expression matrix (UMI counts per gene 61 per cell) was filtered and normalized by using the R package Seurat [1] (Version 3.1.1). Overall, 62 genes detected in fewer than one cell were filtered out, and cells were excluded if they expressed 63 fewer than 500 detected genes, UMI counts less than Inf, and the percent of mitochondrial-DNA derived gene expression below 25%. The Doublet Finder [2] package (version 2.0.3) was also 64 65 employed to filter out doublets. scRNA-seq data that met quality control criteria were used for transcriptomic analysis. 66

67 1.4 Uniform manifold approximation and projections (UMAP) analysis of single-cell RNA-seq
 68 datasets and identification of cell clusters

Following the removal of the low-quality cells and doublets, the "LogNormalize" method in the Seurat package was used to normalize the expression of the data. Then the principal component analysis (PCA) was performed using the "RunPCA" function based on the normalized expression value. Using a Jackstraw substitution test algorithm, we select the top ten principal components (PC) from the PCA analysis results for subsequent unsupervised clustering and cluster analysis. The process of clustering cells was performed using the "FindClusters" function with an appropriate resolution Two-dimensional visualization was obtained with a UMAP[3]. 76 Differentially expressed genes (DEGs) or marker genes for each significant cluster were found 77 using the Wilcoxon rank-sum test (default parameter is "bimod": likelihood-ratio test) as 78 implemented in the "FindAllMarkers" function ($|\log 2 FC| \ge 1$ and adjusted P value ≤ 0.01). Only 79 genes representing or expressing greater than 10% of the cells in a given cluster were considered. 80 Manual annotation (a combination of marker genes identified from the literature, marker gene list, 81 and gene ontology for cell types) was applied to assigned cell cluster identity. The Seurat function 82 of FeaturePlot, VlnPlot, and DotPlot were employed to plot the expression of selected genes. We 83 used heatmap.2 function from the gplots v3.6.1 R package with the default complete-linkage 84 clustering algorithm to construct heat maps.

85 1.5 Inference of differentiation trajectories

Single-cell trajectories were constructed using the R package monocle [4] Version 2.4 with the default parameter settings and the partition-based graph abstraction (PAGA) [5] with an edge significance threshold of 0.6.

89 1.6 Estimation of transcriptional noise

90 Estimation of transcriptional noise was performed mainly based on previous work [6]. Here, 91 we presented two measurements of transcriptional noise. Specifically, we first ensure that each cell 92 cluster has at least 10 cells. In order to avoid the impact brought by different UMI counts, each cell 93 was down-sampled to 100,000 UMIs so that all cells had an equal number of total UMI counts. 94 Similarly, to account for differences in cell-type frequency, we subsampled cell numbers to maintain 95 equal numbers of cells for the two groups. We then divided genes into 10 equally sized bins by mean 96 expression, with the top and bottom bins excluded. The 10% of genes with the lowest coefficient of 97 variation (CV) from each bin were kept. These genes were then used to calculate the Euclidean

98	distance between each cell and its corresponding cell type mean. This Euclidean distance was used
99	as one measure of transcriptional noise for each cell. The ratios of transcriptional noise between
100	neonatal and adult goats for each cell type were subsequently calculated. We also calculated the
101	average Euclidean distances for each goat. Alternatively, we used the 1-Spearman correlation
102	coefficient as the second measure. Spearman's correlation coefficients were calculated using the
103	subsampled gene expression matrices between each cell type and age group (neonatal and adult
104	stages). We then used Wilcoxon's rank sum test to statistically evaluate the relationship between
105	transcriptional noise and age for each cell type. The Bonferroni-Hochberg method was used to
106	correct the p values.
107	

108 **2. Supplementary Figures**

Figure. S1. Transcriptomic characteristics of the goat Pancreas. (A) Split views showed the biological duplicate effect on NG and AG groups. (B) UAMP clustering of 35,449 cells isolated from pancreas of neonatal (NG group) and adult goats (AG group). Cells are colored according to the cluster. Each dot represents a single cell. (C) Expression level of marker of acinar cell in different subsets. (D) Expression level of marker of ductal cell in different subsets.

Figure. S3. Cell-to-cell signaling networks and gene expression alterations of pancreatic endocrine cells of adult goats. Cell-to-cell signaling networks in neonatal goats (A) and adult goats (B). Networks depicting cell types as nodes and interactions as edges. Edge thickness is proportional to the number of interactions between the connecting types. (B) Heat map depicting the number of all possible interactions between the clusters analyzed in neonatal goats (C) and adult goats (D). Volcano map showing the number of DE genes between cells from AG and NG samples in β (E) and δ (F), with red and blue colors corresponding to up-and-downregulated genes in AG samples, respectively. Non-differential genes are shown in grey color.

3. Supplementary Tables

Table. S1. Overview of key genes from scRNA-seq data, divided by each cell
compartment, that exhibit relatively high or specific expression in each cell types used
for characterization annotation, related to Figure 1.
