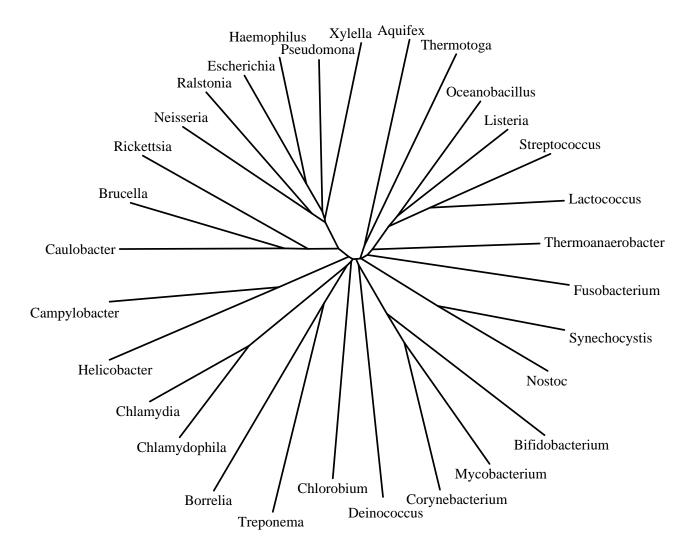

Figure S1: We computed a tree directly from a consensus distance matrix  $\{\mathbf{D}(i,j)\}$  to test how well the matrix conformed with a tree metric. The consensus distance matrix used for this figure was computed from 200 families of orthologous sequences of length 300. The tree was computed using the Fitch-Margoliash algorithm (program FITCH from the package PHYLIP), and gave an average percent standard deviation of 1.51%, meaning that a typical pairwise distance in the tree deviates by 1.51% from the distance in the matrix. The tree correctly reconstructs accepted clades such as Proteobacteria and Actinobacteria, but shows poor resolution in the center. The 30 organisms in the tree above were the 30 organisms used in the initial overall computation of the tree in Figure 1.

| Gene | Class | Name  | COG  | Rank | Coeff |

Table S1: Representative proteins used to root the bacterial tree of Figure 1. Sequence lengths in the first block are 180 and in the second block 60. The Rank column gives the conservation rank compared to other sequences of the same length; thus a 180-long sequence from elongation factor TU has rank 2 among 180-long sequences and a 60-long sequence from RNA polymerase, beta' subunit, has rank 2 among 60-long sequences.

Table S2: Representative proteins used to compute the initial, overall tree for Figure 1. Sequence lengths within the first block are all 300, second block 240, third block 160, and fourth block 130. Correlation coefficients are lower than in the other lists, because of the number and diversity of organisms. It is possible that almost all proteins have been horizontally transferred at some point within the history of Bacteria; in this case representative proteins are the ones with the least obvious—and hence least misleading—transfers.

Table S5: Some proteins with anomalously small evolutionary distances between distant taxa, presumably due to horizontal transfer between ancestors. Notice that even "informational" proteins such as ribosomal proteins and tRNA synthetases are subject to horizontal transfer. Class refers to the COG (clusters of orthologous groups) functional codes given in Table S6.

|   | Information storage and processing                           |
|---|--|
| J | Translation, ribosomal structure and biogenesis              |
| K | Transcription  |
| L | DNA replication, recombination and repair                    |
|   | Cellular processes   |
| D | Cell division and chromosome partitioning                    |
| O | Posttranslational modification, protein turnover, chaperones |
| M | Cell envelope biogenesis, outer membrane                     |
| N | Cell motility and secretion                                  |
| P | Inorganic ion transport and metabolism                       |
| T | Signal transduction mechanisms                               |
|   | Metabolism   |
| C | Energy production and conversion                             |
| G | Carbohydrate transport and metabolism                        |
| E | Amino acid transport and metabolism                          |
| F | Nucleotide transport and metabolism                          |
| Н | Coenzyme metabolism  |
| I | Lipid metabolism   |
| Q | Secondary metabolites biosynthesis, transport and catabolism |
|   | Poorly characterized   |
| R | General function prediction only                             |
| S | Function unknown   |

Table S6: Functional categories of COGs.
