

This is an appendix to the paper by Key & Ross 1999 Sex differences in energy expenditure in non-human primates. *Proc. R. Soc. Lond. B* **266**, 2479-2485.

Electronic appendices are refereed with the paper. However, no attempt has been made to impose a uniform editorial style on the appendix.

ELECTRONIC APPENDIX A: DATA AND DATA COLLECTION

In order to assess both short-term (daily energy expenditure) and long-term (the energetic cost of reproduction) energy demands, the following data are required: male and female activity budgets, male and female body mass, day range, gestation length, weaning age and inter-birth interval. These data were primarily collected from the literature; Data and data sources are shown in tables 1 and 2. A complete data set was available for 19 haplorhine primates, representing a good cross-section of genera: 7 Cebidae, 8 Cercopithecidae, 1 Hylobatidae and 3 Hominidae.

Only data from wild populations were used for activity budgets, male and female body mass and day ranges. Activity budget data were taken from the available literature, which usually divides activities into time spent sleeping, resting, moving, feeding and socialising. In two instances (*Callicebus torquatus* and *Ateles paniscus*) time spent socialising was not recorded. In many studies a small percentage of activity time was recorded as unknown. In these cases, it was assumed that the various activities performed during the unknown period occurred in the same proportion as during the observed period. It is noteworthy that time spent sleeping is 50% in nearly all cases. Since animals are rarely watched during the night, it is unclear whether they really are inactive for the whole of this time or whether other activities, such as socialising, occur. In the absence of data, it is assumed that this time is devoted only to sleeping.

Every effort was made to collect data on other parameters from the same study site as used for the activity budget data, or, if this was not possible, from an ecologically similar site (table 2). In some instances data from captive populations were also used for inter-birth interval and weaning

age, although this was avoided wherever possible. In many cases gestation lengths from captive animals were used, as these values are generally more accurate than those estimated from wild animals. For a few species, it was not possible to find gestation lengths, and in the following cases mean values for related species of the same size were used (shown in brackets): *Ateles paniscus* (*Ateles* mean), *Brachyteles arachnoides* (*Ateles* mean), *Callicebus torquatus* (*Callicebus moloch*) and *Colobus badius* (*Colobus polykomos*). Similarly, in the absence of data, lactation length of *Callicebus moloch* was used for *Callicebus torquatus*. Body mass data were not always available from the same site as used for activity budget data. In these cases data from nearby populations of the same subspecies were used. Body masses are mean values for each group, and hence do not take seasonal weight fluctuation into account. Ideally the influence of such fluctuations on metabolic costs would be calculated, but the lack of detailed data for most species makes this impossible here.

Table 1. Time budget data

(Values are expressed as percentage of day spent feeding (F), resting (R), moving (M), socialising (So) and sleeping (Sl). Study sites are shown under the species names).
