Regions showing significant placebo effects in heat as compared with warm stimulation. Abbreviations are given in the text. All effects are increases (positive effects). X, y, and z refer to activation center of mass coordinates in mm relative to the anterior commissure in Montreal Neurological Institute space (based on the SPM2 avg152T1.img template brain). Vol.: volume of activation. Max T: maximum absolute t-value in the region. SVC t-threshold: nonparametric significance threshold for small-volume corrected (SVC) significance at corrected $p < .05$, one tailed. Correlation with RP: Maximum absolute partial correlation among activated voxels between opioid activity ([P – C Heat] vs. [C – P Warm]) and reported placebo analgesia (RP). % Increase: Placebo effect expressed as a percentage of baseline binding. Baseline binding was calculated as the average binding in the high-opioid-binding mask (average binding = 1.30 across regions). +, $P < .10$; *, $P < .05$; ***, $P < .005$, all two-tailed. L, left; R, right.
