

Sequence of the *Escherichia coli pheST* Operon and Identification of the *himA* Gene

YVES MECHULAM, GUY FAYAT,* AND SYLVAIN BLANQUET

Laboratoire de Biochimie, Unité Associée No. 240 du Centre National de la Recherche Scientifique, École Polytechnique, 91128 Palaiseau Cedex, France

Received 28 January 1985/Accepted 6 May 1985

The complete nucleotide sequence of the *Escherichia coli pheST* operon coding for the two subunits of phenylalanyl-tRNA synthetase (an $\alpha_2\beta_2$ -type enzyme) has been determined. Another open reading frame (*prp*) was revealed downstream from *pheT* which was identified as *himA*, the gene for the α subunit of the integration host factor.

The *Escherichia coli pheST* operon codes for the small (β) and large (α) subunits of phenylalanyl-tRNA synthetase, a tetrameric enzyme of the $\alpha_2\beta_2$ type (5). These two genes, which map at 38 min on the chromosome (3), were isolated on a λ transducing phage, $\lambda p2$, and subcloned in pBR322 to give plasmid pB1 (Fig. 1) (8, 16). In vitro and in vivo studies (6, 23) strongly suggested that *pheST* transcription was controlled by a phenylalanine-dependent attenuation mechanism. More recently, the physiological behavior of mutants isolated in vivo or obtained in vitro by the creation of short deletions or insertions or of site-directed point mutations firmly established the presence of an attenuation mechanism (10, 22; J. F. Mayaux, G. Fayat, M. Panvert, M. Springer, M. Grunberg-Manago, and S. Blanquet, J. Mol. Biol., in press).

In this study, the sequence of the 2,688-base-pair (bp) *PstI-HindIII* region of pB1 was resolved by the dideoxy chain termination method (20), with recombinant M13mp8 and M13mp9 phage DNA used as the template (11) (Fig. 2). The first open reading frame to the right of the *PstI* site (nucleotides 1 to 221, Fig. 3) corresponds to the 3' end of the *pheS* structural gene, as previously reported (6). The second open reading frame, starting at nucleotide 239, previously identified as the beginning of the *pheT* structural gene (6), was 2,385 nucleotides long and accounted for a polypeptide of M_r 87,024. The deduced M_r of phenylalanyl-tRNA synthetase, 247,562, was in good agreement with previous determinations done by equilibrium centrifugation ($240,000 \pm 10,000$ [5]) and neutron scattering ($227,000 \pm 20,000$ [4]).

To search for a recognizable transcription termination signal downstream from the *pheST* operon, an 850-bp *SacII-SacII* fragment from the *pheST* transducing phage $\lambda p2$ (Table 1) was cloned into the single *SacII* site of plasmid pHL78 to give recombinant plasmid pHIII-2 (Fig. 1). This plasmid carries the 3'-terminal end of *pheT* (153 bp) and a large 3' flanking region (700 bp). The nucleotide sequence of the $\lambda p2$ *SacII* fragment was determined and combined with the sequence of the *PstI-HindIII* fragment of pB1 (Fig. 3). Downstream from *pheT*, on the same DNA coding strand and in a different coding phase, an open reading frame (*prp*) of 297 nucleotides was found. The first possible AUG initiator codon for this *prp* open reading frame was separated by only 7 nucleotides from the UGA stop codon of *pheT* and was preceded 10 bases upstream by a GAGG sequence internal to *pheT*, indicating a strong translation initiation

signal (21). In addition, 15 nucleotides downstream from the stop codon of *prp*, there was a region of dyad symmetry followed by a stretch of T's resembling a rho-independent transcription terminator (18).

It is known (14) that $\lambda p2$ expresses one of the two subunits of the integration host factor (IHF) coded by *himA*, the other subunit being encoded by the *himD* gene (also called *hip* [13]). On the other hand, $\lambda p2$ suppresses the $HimA^-$ phenotype (12). Moreover, *pheST* and *himA* are 95% cotransducible by phage P1 (14). Thus, *himA* should be located very close to the *pheST* operon on the *E. coli* chromosome, the order of these genes being *pheS-pheT-himA* (2). Since the M_r

* Corresponding author.

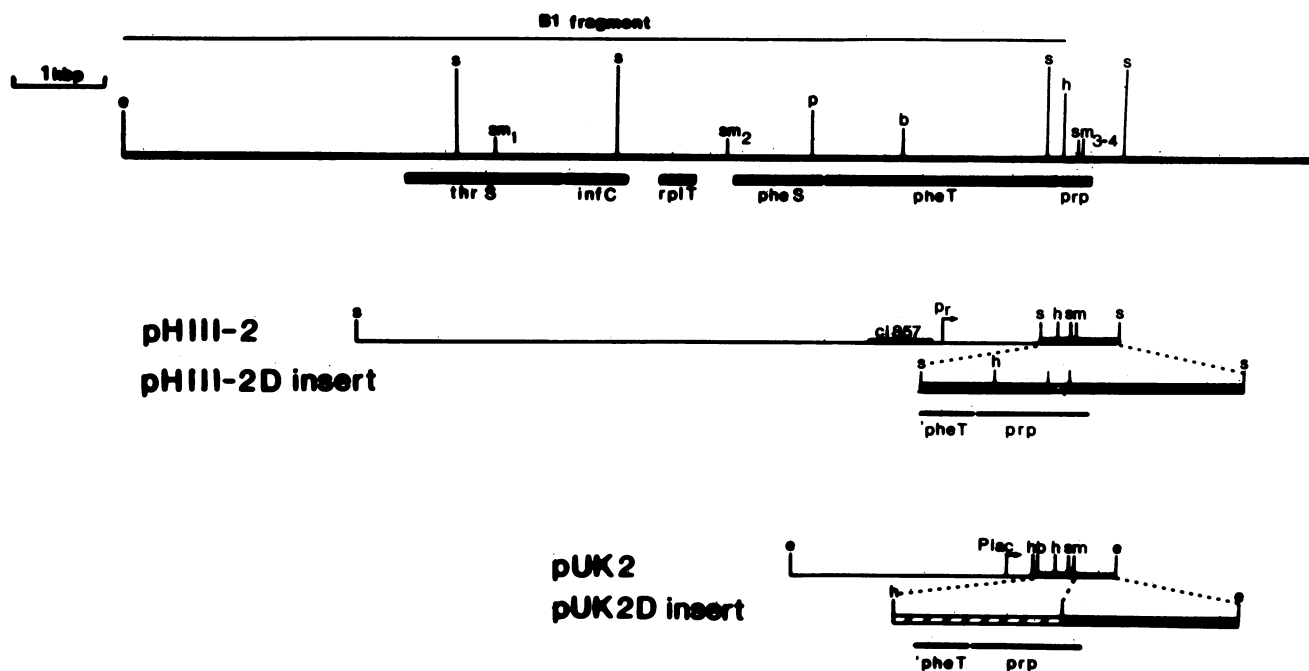

FIG. 1. Physical map of the *E. coli* chromosomal fragment carried by λ p2. (Top) Relevant region of the λ p2 insert. The *EcoRI*-*HindIII* fragment (B1 fragment) cloned in pBR322 to give plasmid pB1 is indicated. The locations of *thrS*, *infC*, *rplT*, *pheS*, and *prp* (*himA*), coding for threonyl-tRNA synthetase, initiation factor IF3, ribosomal protein L20, the β and α subunits of phenylalanyl-tRNA synthetase, and the α subunit of IHF, respectively, were deduced from DNA sequence data (6, 9, 19; this work). kbp, Kilobase pairs. (Center) Partial restriction map of pHIII-2, obtained by inserting the 850-bp *SacII*-*SacII* fragment of λ p2 into the single *SacII* site of plasmid pHL78. *prp* transcription on pHIII-2 is under the control of the strong inducible P_R promoter of phage λ (arrow). pHIII-2D was derived from pHIII-2 after deletion of a 67-bp *SmaI*-*SmaI* fragment internal to *prp* (hatched box). (Bottom) Partial restriction maps of pUK2 and its derivative pUK2D. pUK2 was obtained as follows: the *SacII* insert of pHIII-2 was cloned in the *SmaI* site of M13mp8 after digestion of the *SacII* 3'-protruding termini by T4 DNA polymerase. After transfection and characterization, the recombinant phage DNA was digested with *EcoRI* and *BamHI* (both present on the polylinker of M13mp8), and the resulting fragment was cloned in the corresponding sites of the pUC13 vector. In this plasmid, *prp* transcription is under control of the *lac* promoter (arrow). By using the *HindIII* site in the polylinker of pUC plasmids, a 438-bp *HindIII*-*SmaI* fragment (hatched box) carrying the 3' end of *pheT* and most of *prp* was deleted, creating pUK2D. Restriction enzyme cleavage sites: e, *EcoRI*; s, *SacII*; sm, *SmaI*; h, *HindIII*; b, *BamHI*; p, *PstI*.

of the putative *prp* product, 11,302, coincided with that of the *himA* protein, 11,000 (14), it was of interest to test the ability of *prp* to complement an *himA* mutant (*himA42*).

Two *prp*-bearing plasmids were used for complementation experiments: pHIII-2 and pUK2, a derivative of pUC13 carrying the *SacII* fragment (Fig. 1). Complementation was

FIG. 2. Sequencing strategy for *pheT* and flanking regions. Arrows show the nucleotides sequenced by the dideoxy chain termination method. Recombinant M13mp8 or M13mp9 DNA was used as the template. Phage clones containing the *pheT* gene up to the *HindIII* site were constructed with pB1 as the source of DNA,

monitored with bacteriophage Mu, which does not grow in *himA* strains (12). Strain K936 (*himA42*) transformed by either pHIII-2 or pUK2 recovered the ability to support Mu plaque formation (Table 2). To show that *himA* suppression by pHIII-2 or pUK2 depended on the integrity of the *prp* coding phase, the same experiments were performed with modified plasmids pHIII-2D and pUK2D. pHIII-2D is a derivative of pHIII-2 obtained by deleting the 67-bp *SmaI* fragment internal to *prp* (Fig. 1). This deletion removed 36 codons in the 3' end of *prp* and should result in a truncated protein of 64 amino acids. In plasmid pUK2D (Fig. 1), the DNA region corresponding to the 3' end of *pheT*, the intergenic *pheT*-*prp* region, and the first 83 codons of *prp* have been removed. Both of the truncated *prp* genes were unable to suppress the *HimA*⁻ phenotype (Table 2). Finally, the burst size of phage Mu was used as a quantitative measurement of *HimA*⁻ phenotype suppression. The results (Table 2) confirmed that *prp* carried by pUK2 suppressed the *HimA*⁻ phenotype. The average burst size of the native *HimA*⁺ phenotype (strain K37) recovered by 70% after

whereas clones containing the *SacII*-*SacII* region were derived from pHIII-2. The DNA sequence of the first 300 nucleotides of the *pheT* structural gene had already been determined (6) by the chemical sequencing method.

suppression of the mutation. These results strongly suggest that *prp* corresponds well to the *himA* structural gene.

Several studies have demonstrated that the *himA-himD* product complex (IHF) is able to bind DNA with high affinity (15). Therefore, it is worthwhile noticing that the *prp* product has extensive homology with several prokaryotic, DNA-binding proteins, including NS1 and NS2 (HU α and HU β) from *E. coli*, DNA-binding protein II from *Bacillus stearothermophilus*, and class II DNA-binding proteins from

K936(pHIII-2D)	-	ND

^a Burst values of Mucts62 were measured by the method of Miller and Friedman (12). It was verified that transforming strain K37 with the various plasmids did not significantly affect either Mucts62 plaque formation or Mu phage burst.

^b ND, Not determined.

Rhizobium meliloti, *Clostridium pasteurianum*, and *Thermoplasma acidophilum*. For each of these proteins, the number of amino acids identical to those in the *B. stearothermophilus* sequence was between 29 and 54; for *prp*, comparison with the *B. stearothermophilus* protein showed that 39 amino acids were strictly conserved (Fig. 4). The three-dimensional crystal structure of the *B. stearothermophilus* DNA-binding protein II has been solved at a resolution of 3 Å (0.3 nm) (24). It is striking that the highly conserved amino acids responsible for its hydrophobic core and therefore for its dimer stability, i.e., Phe-29, -47, -50, and -79, Ile-32, and Leu-6, -36, and -44, are also found at the same positions in the *prp* product, except for the methionine at position 6 (Fig. 4). In addition, the arm region of the *B. stearothermophilus* protein (Fig. 4), thought to be involved in nucleic acid interactions, corresponded to the highly homologous region among the seven proteins, including the putative *prp* product (homologies between the *himA* product and HU were recently quoted in a personal communication from H. I. Miller in reference 7).

To conclude, the proximity of *pheST* and *himA*, as shown by the DNA sequence, suggests a link between the expression of these genes. The nature of the link and the possible role of *lexA* (13) in the expression of this cluster of genes are currently under study in our laboratory.

We gratefully acknowledge the help of Jean-Francois Mayaux at the initial stage of this work and the continued interest and support of Marianne Grunberg-Manago and Mathias Springer. We also thank Philippe Dessen for helpful advice and computer assistance.
