

Figure S2 Schematic representation for TOR mediated control of G1 cyclins and Msn2/4 nuclear translocation. Tor controls the synthesis of G1 cyclin by controlling the translational initiation of *CLN3* mRNA. Cln3 activates SBF, a transcriptional activator of Cln1/2. SBF is inactivated by mitotic cyclin, Clb2. Tor negatively regulates the phosphatase Pph21/22 under nitrogen rich condition, which is required to decrease the export rate of Msn2/4 from the nucleus. The term Tpk represents the input from cAMP pathway, which is required to decrease the import rate and increase the export rate.
