

SUPPLEMENTAL MATERIAL

Figure S1. The *TBC1D3* locus is duplicated several times on chromosome 17. (A) Snapshot adapted from the UCSC Genome Browser (<http://genome.ucsc.edu/>) showing the position of the *TBC1D3* loci found duplicated in chromosome 17. BAC clones position in the assembly and their accession numbers are shown; specific BACs containing the *TBC1D3* loci are highlighted in red, and their sequences are complete. Gene composition of the region is also provided. The possibility that these duplicated loci are the consequence of a wrong assembly of the human genome can be excluded for several reasons. Firstly, all copies of the *TBC1D3* gene are entirely contained in BAC clones whose sequences are complete. Four BACs contain two copies each of the *TBC1D3* gene, which represents the only common portion of sequence. Secondly, (B) two copies of the *TBC1D3* gene lay in a region of the chromosome 17 containing also the *CCL3* and *CCL4* genes, which also underwent several rounds of segmental duplication during evolution (Modi, 2004). Lastly, (C) a recent duplication of the *TBC1D3* ancestral locus that preceded a fusion event with a duplicated *USP32*, gene must be invoked to account for the generation of *USP6* (Paulding *et al.*, 2003). In line with this, *TBC1D3* duplicated locus at 17q23.2 (chr17:55440265-55451181) maps very closely to the *USP32* gene (~200 Kbp), suggesting that proximity of the two “ancestral genes” might have favored a recombination event during the evolution of chromosome 17 in the primate lineage.

Figure S2. Exon and intron length conservation among the loci of *TBC1D3* and *RNTRE* from different organisms, and their protein products.

(A) Exon and intron length of Human *TBC1D3* and *RNTRE*, and of Mouse and Xenopus *RNTRE*. Length of intron 5 and 6 of the Xenopus *RNTRE* locus cannot be assessed due to gaps in the genomic assembly. (B) Multiple alignment of the protein product of the above mentioned loci. ClustalX colors (reflecting the chemical properties of the aminoacids) are applied whenever group conservation exceeds 50%. GenBank protein accession numbers are as following: Hs_RNTRE: AAH42943; Hs_TBC1D3; NP_115634; Mm_RNTRE: BAC97847; Xt_RNTRE: ORF predicted from mRNA CT030299.

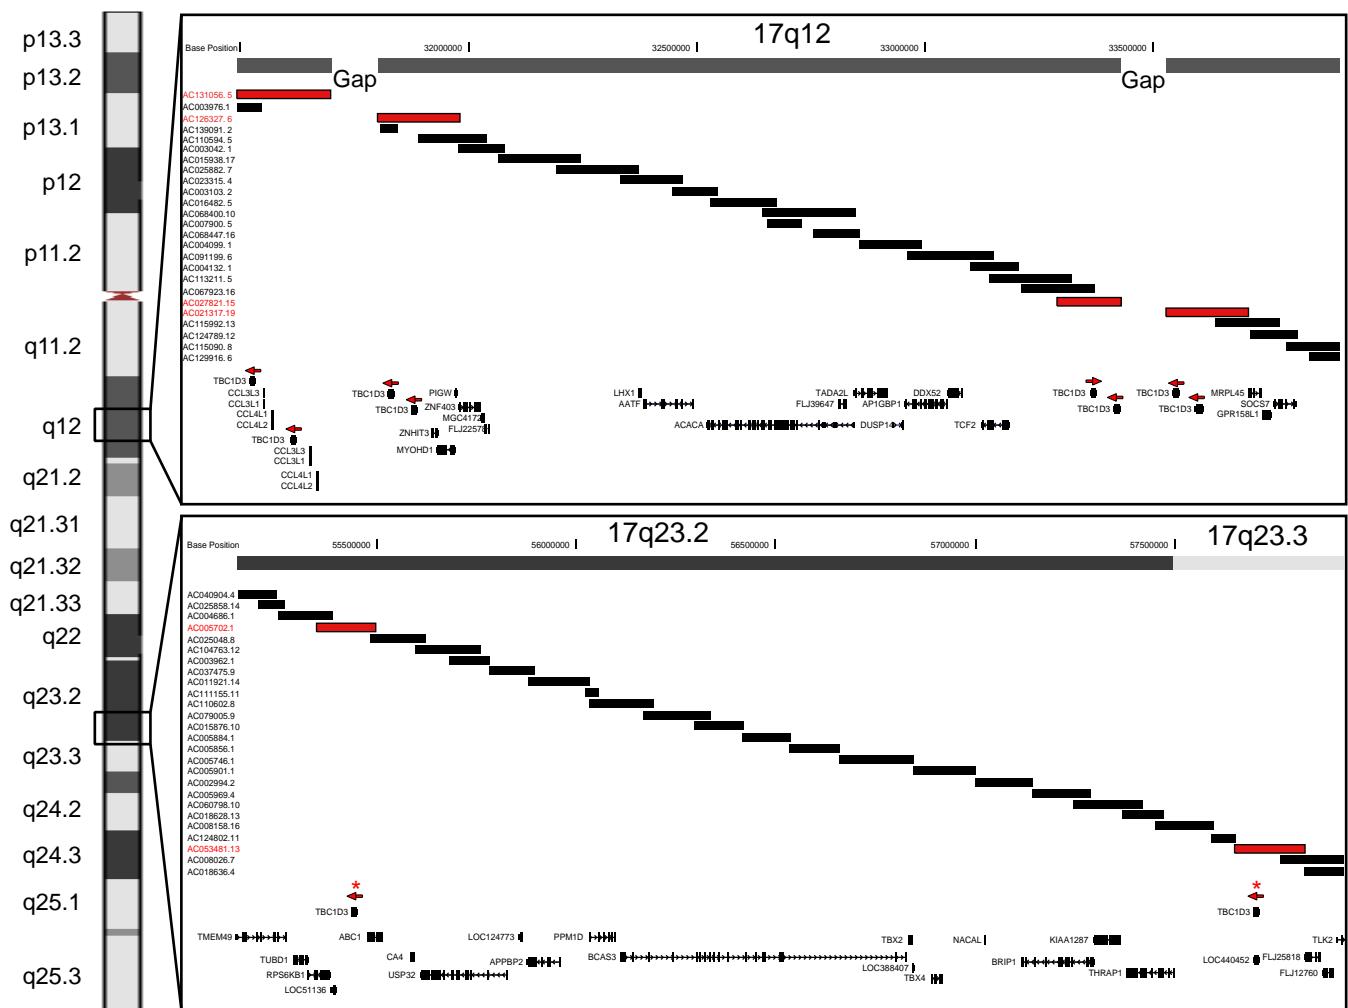

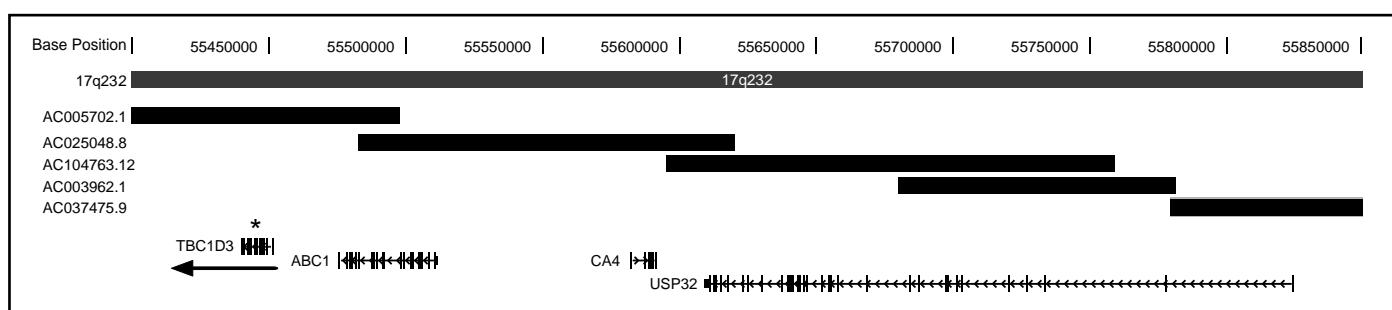

Figure S3. Quantification of colocalization between TBC1D3, GGA3 and ARFQ67L.

The extent of colocalization of coexpressed proteins in the experiments shown in Fig. 6 B-C of the main manuscript is reported at the left of each image, and was monitored using ImageJ (<http://rsb.info.nih.gov/ij/>, Colocalization Threshold plugin). After fixing the threshold values for each channel, spatial correlation was calculated and colocalizing pixels highlighted in white. The tables report the Manders Coefficients (tM1 and tM2, corresponding to the indicated color-coded signals of the expressed proteins), calculated over intensities higher than the set threshold.
