Table 2.2 Frequencies of genes with a putative $\sigma 70$ promoter harbouring an UP element, under two constraint sets, in 32 prokaryotic genomes. *n*: micro-organism name; *a*: abbreviation for micro-organism name (see Table 2.1); *at*: average percentage of nucleotides T and A over the 350 bp-long region upstream of start codon, computed over the total number *g* of genes in the genome; *upsp_{CI}*: number of genes with an UP element harboured in the Strong Promoter region, identified under constraint set *CI*; *upsp_{CII}*: *idem*, under the more relaxed constraint set *CII* (see text, Section "Genome analysis upon request" for the definition of *CI* and *CII* constraints); $p2_{CI} = 100 \times upsp_{CI}/sp_{CI}$, $p2_{CII} = 100 \times upsp_{CII}/sp_{CII}$, with *sp_{CI}* (resp. *sp_{CII}*) the number of genes harbouring a Strong Promoter under constraints *CI* (resp. *CII*). The percentages indicated in the two rightmost columns are respectively $p1_{CI} \times p2_{CI} = upsp_{CI}/g$ and $p1_{CII} \times p2_{CII} = upsp_{CII}/g$, that is the ratio of the number of genes identified with an UP element in their putative strong promoter, to the number *g* of genes encoding proteins in the genome considered.
