

Dataset S6. Basal metabolic rates in birds

McKechnie & Wolf (2004, Table A1) analyzed whole-body basal metabolic rates Q (W ind⁻¹) as compiled by Reynolds & Lee (1996) for 254 bird species, to find that in 42 cases the conditions for measurements of basal metabolic rate had not been met. Those 42 values were not analyzed in our study. Additionally, McKechnie & Wolf (2004, Table A2) compiled literature data on basal metabolic rate in 60 bird species.

In some cases where no sufficient details were given in the published study, McKechnie & Wolf (2004) contacted the authors to ensure that basal metabolic rate conditions were strictly met. Most data of V. Gavrilov (Gavrilov 1974; Kendeigh, Dol'nik & Gavrilov 1977, ~60 species), who had not been contacted, were presented in Table A1 of McKechnie & Wolf (2004) as having an unknown or small ($n < 3$) number of individuals measured.

Below in Table **S6a** the following data are presented. 314 values from McKechnie & Wolf (2004) (254-42+60) were pooled with 113 values of basal metabolic rate of 113 bird species measured by V. Gavrilov. As no sufficient details about the data of V. Gavrilov are present in the international literature, these data are provided below in a separate Table **S6b** with a detailed description of the measurement procedure, the number of individuals studied, time and season of measurements and reference publications.

In the resulting compilation of 385 values, some species were represented twice, like where McKechnie & Wolf (2004) cited the work of Gavrilov (1974) or Kendeigh, Dol'nik & Gavrilov (1977), or where two or more studies investigated one and the same species. In the former case the original value provided by V. Gavrilov in Table **S6b** was taken. In the latter case the lowest value for the species was chosen. This yielded a total of 321 BMR values for 321 species that are presented in Table **S6a**. These values were used in the analyses presented in Table 1 and Figures 1-3 in the paper.

Table **S6b**. Basal metabolic rate in birds (experimental data obtained by V. Gavrilov)

Notes on measurements procedure. Basal metabolism is the rate of energy utilization by a bird at complete rest, without the energetic costs of digestion and assimilation of food or cold stress, i.e. the rate of energy utilization of fasting, inactive birds in the zone of thermoneutrality. Basal metabolism was determined by measuring rates of oxygen consumption in closed boxes of different volumes, where CO₂ was absorbed using NaOH or KOH (closed-circuit respirometry). Basal oxygen consumption was measured in birds under postabsorptive conditions at night (N), as indicated in Table **S6a**, at different ambient temperatures that allowed strict determination of the thermoneutrality zone. The larger birds were deprived of food from mid-day, and the smaller birds from 3 to 4 hours before the nightfall. The birds were placed singly in small cages, which were then placed in plexiglass chambers in the dark. The chamber sizes varied from 3 to 25 liters, depending on the size of the bird. The flow of air through the chamber was controlled, and after stabilizing chamber temperature, the outflow was connected to an oxygen measuring instrument. Actual measurements of oxygen consumption were never started earlier than 1-3 hours after dusk and always ended 1 to 2 hours before dawn. Each experiment lasted from 1 to 4 hours. Tests were done at the beginning and end of the experiments to make certain that the boxes were properly sealed. Measurements were also done in the daytime on birds with different amounts of food in the alimentary tract. **The number of individuals measured varied from two (*Tetrao urogallus*) or three-four (in some large nonpasserine birds) to eight-twelve (in most other species) and up to 20-35 (in well-studied species, like for example *Parus major*, *Fringilla coelebs*).** The birds were weighed early at the beginning and at the end of the experiment. If the change of body mass was small (not more than 1.5-2% of body mass), corrections were made using a caloric equivalent equal to 25.1 kJ g⁻¹. If the change of body mass was greater, the data were not used.

Notations:

Mg — mean body mass, g; *N* — number of measured birds;

D — measurements were made during the active (day-time) phase of the avian circadian cycle;

N — measurements were made during the resting (night-time) phase of the avian circadian cycle;

W — measurements were made during the nonproductive "winter" phase of the avian annual cycle;

S — measurements were made during the reproductive "summer" phase of the avian annual cycle;

A — measurements were made during the nonproductive "autumnal" (postmoult) phase of the avian annual cycle;

V — measurements were made during the early part of the productive "vernal" phase of the avian annual cycle;

Y — measurements were made during the whole year;

QkJday — whole-body basal metabolic rate, kJ ind⁻¹ day⁻¹.

Note: data in Table S6a marked "G" are taken from Table S6b and correspond to the minimum night-time (N) mass-specific basal metabolic rate for the corresponding species, qWkg = (QkJday/Mg)×10⁶/24/3600 W kg⁻¹.
