Each model is run 100 times until the number of nodes reaches 3000. The average degree is constant ($\langle k \rangle = 8.0$) for PA, AP and CG model but is variable in DD model depending on the parameters p and q.

¹ In DD model, p=the connection probability between duplicates, q=the divergence probability. In CG model, the module is defined by the method by Newman or TCC (triangularly connected component).

² average degree

³ the degree exponent in $P(k) \sim k^{-\gamma}$

⁴ the number of triangles per edge

⁵the mixing exponent in $\langle k_{nn} \rangle(k) \sim k^{-\delta}$
